I. Metallic Currency.—The metallic circulation of the United Kingdom consists of gold, silver, and copper. The actual amount of gold and silver coin in circulation at any given time within the country cannot be estimated by the amount of the metal coined; for gold and silver moneys are exported whenever a profit can be made by their exportation. The amount of moneys coined at the Mint in the year 1835 (the last return is of that year) was as follows:—gold, 1,109,718*l.*; silver, 146,665*l.*; copper, 2688*l.* It has

been asserted that the average amount of our gold currency, exclusive of the amount retained by the Bank of England, is 30 millions; but the data for such an estimate are necessarily shifting and uncertain. The circulation of silver coin in this country is of very inconsiderable amount. This is the main difference between the metallic currency of the United Kingdom and that of the rest of the world. The total existing quantity of gold, when compared with the existing quantity of silver, has been stated to be as about 1 to 50, and the relative value of gold to silver is as 1 to about 15; consequently the value of the general silver currency of the world as compared with the gold currency, is somewhat more than as 3 to 1. In this country, however, gold is the only legal tender for sums above forty shillings, and consequently the metallic currency is essentially gold, the silver coins being, like the copper, only a sort of tokens auxiliary to the gold. By the present Mint regulations, a seignorage, or duty, is charged on the silver coinage, amounting to 6½ per cent: upon the gold coinage no seignorage whatever is charged. A pound troy of the metal of which our silver coin is made consists of 11 oz. 2 dwts. of pure silver and 18 dwts. alloy; it is coined into 66 shillings. Our gold coins contain 11 parts fine gold and 1 part alloy; a pound troy of which mixture (called standard gold) is coined into 46 sovereigns and 14s. 6d. The bullion value of the silver coinage being therefore more than 6 per cent. less than the gold coinage, that portion of our metallic currency remains perfectly subsidiary to the gold currency; there is no necessity for determining the relative values of the two species of currency by an agio; the silver of the world necessarily goes to other countries where it forms the basis of the currency, either exclusively or in connexion with gold. Our metallic system of currency was established by law in 1816, although in practice the same principle had long prevailed, in consequence of the relative values of gold and silver in our Mint regulations. The English system gets rid of the complexity of a double standard, but there is reason to apprehend that this apparent simplicity may be purchased at too high a price. Our standard being that of the metal which is 50 times less in quantity and more than 3 times less in total value than the standard adopted by other nations, the fluctuations in the value of our standard are necessarily more frequent and more extensive than in the standard of silver, or in a standard of gold and silver exchangeably. Gold possessing large value in small bulk is in greater demand than silver when money is required for the purposes of governments. Mr. Rothschild told the Bank Charter Committee in 1832, that 'When the Emperor of Russia made war in Poland lately, gold which went from Hamburgh to Petersburg and Warsaw was paying from three to four and five per cent profit.' Such operations of course suddenly affect the price of gold; and their results in altering the exchangeable value of commodities, and in contracting the entire currency, are most severely felt where gold is the standard.

II. *Paper Currency*.—This may be divided into—1. Bank Currency: 2. Private Currency. The paper currency proceeding from banks of issue consists of the notes of the Bank of England, and the notes of country banks, whether private or joint-stock banks. The circulation of the Bank of England in October, 1836, was 17,936,000*l.*; that of the private banks in September, 1836, was 7,764,824*l.*; and that of the joint-stock banks at the same date was 3,969,121*l.*; making a total bank currency of 29,669,945*l.* This bank currency of about 30 millions is based upon our metallic currency, and is convertible into that upon demand. Bank of England notes are legal tender, by the Bank Charter of 1834, by country banks; but at the Bank of England and its branches, Bank of England notes are payable in gold. The Bank of England therefore requires a sufficient supply of bullion to meet the possible demand for specie. That demand in recent times has arisen not from any want of confidence in the solvency of the Bank of England at home, but from the state of the foreign exchanges, which causes specie to be sent abroad. It is held that the only sound principle of managing a currency consisting partly of coined money and partly of paper money, is to have some authority presiding over the issues of paper which will be adequate to preserve the currency in the same state with reference to other countries as if it were purely metallic; and that the Bank of England, holding this authority, ought invariably to allow the currency to expand and contract under the action of the foreign exchanges. The monetary crisis of

1836-7 has been asserted to have been produced by a neglect of this principle, the drain upon the bullion of the Bank not having been followed by a proportionate reduction in the circulation of its notes. The examination of this and other questions affecting our currency may be better postponed to future articles. [EXCHANGES; MONEY.] 2. *Private Paper Currency* consists of bills of exchange and cheques upon bankers. The total amount of this credit currency in the United Kingdom is enormous. It is peculiarly liable to abuse; but the vast commercial business of the country could not be carried on without bills of exchange, which, passing from hand to hand, discounted and re-discounted, perform the functions of money. The deposits of individuals with bankers are considered by some economists to perform the same function; in both cases credit becomes a substitute for currency. The doctrine that 'bank deposits perform the functions of money,' has been lately brought forward by Colonel Torrens, but it was first promulgated by Mr. Pennington in 1829. We subjoin the statement of this doctrine in the words of Colonel Torrens, leaving for the present any examination of the probable extent of the operation of the principle:—

'Let us assume that the merchants and dealers within the metropolitan district require for the conducting of their business circulating money to the amount of 10,000,000*l.*, and that they actually hold this amount in coin and Bank of England paper. This being the previous state of things, let us assume again, that these merchants and dealers open accounts with the London bankers, and place with them, as deposits, the 10,000,000*l.*, in coin and notes, which they before kept in their own desks. Now this change in the manner of keeping the cash required to meet the current demands of the market, would not leave the merchant and dealer with a less command of money, with a less power of making payments and of making purchases, than they before possessed. By drawing checks upon their bankers to the amount of 10,000,000*l.*, they can come into the market just as effectually as they could before have done by bringing out coin and notes to that amount from their own cash boxes. If the whole of the 10,000,000*l.* in coin and notes deposited with the bankers were locked up in their coffers until drawn out in payment of the checks of the depositors, this locking up of coin and notes would have no conceivable effect in depriving the depositors of the power of drawing checks, and of making payments or purchases to the amount of the 10,000,000*l.* It is evident, therefore, that transferring coin and bank paper from the desks of merchants and others, and placing them for safe custody as bank deposits, could have no effect whatever, either in contracting or in expanding the currency, even if the whole of the coin and bank paper so transferred were locked up in the coffers of the bank until withdrawn in payment of the checks of the depositors. But the whole of the coin and notes deposited with the banks would not be locked up until required in payment of the checks drawn by the depositors. Bankers make their profit by lending, upon available securities, the greater part of the sums deposited with them by their customers. When our merchants and dealers deposited 10,000,000*l.* with the banks, the bankers would retain a part of the sum—say 2,000,000*l.* as a reserve, or rest, for the purpose of making occasional payments over their counters, and would employ the other 8,000,000*l.* in the purchase of stock, or of exchequer bills, or in the discount of bills of exchange. Now, it is self-evident that this would occasion an extension of the general medium of exchange. The merchants and others who had deposits with the bankers to the amount of 10,000,000*l.* would be just as able as they were before to come into the market and make payments and purchases to the amount of 10,000,000*l.*; while the persons who sold the stock and the exchequer bills, or who obtained the discounts, would be able to come into the market, and effect payments, and make purchases, to the amount of 8,000,000*l.* Thus, in this case, which has been taken for illustration, the operation of the private banks in receiving deposits, and in investing them in available securities, would have the effect of increasing the circulating medium by 8,000,000*l.*' (*Letter to Lord Melbourne*, 1837.)

CURRENT. Current water is opposed to stagnant water, and commonly used to express the motion of water in rivers, produced by the continuous but varying inclination of the bed of the streams. The word current is likewise applied to the rapid motion of the air. Further, it is

used to designate the great masses of moving water, which, in modern times, have been found to exist in the ocean, and which constitute the currents of the sea.

CURRENTS AT SEA are large masses of water in the ocean or in closed seas, which are in continual motion in a certain direction; and so far they may be compared with the currents of rivers. But they occupy a much greater extent of surface, running sometimes two or three thousand miles, with an average breadth of two or three hundred miles. Though their existence was doubtless known to some of the early navigators, it is only in modern times that they have attracted general attention, and that a few facts respecting them have been collected, most of which are found in Major Rennell's very valuable treatise on the currents of the Atlantic Ocean.

Some of these currents traverse the ocean near the equatorial line, and generally run east or west, if they are not deflected from their course by the opposing land. Others, which seem to have their origin near the poles, generally run in a southern direction as far as the tropics, and sometimes farther. The currents at sea run in some parts with an increased, and in others with a decreased, rapidity; and, as might be naturally inferred, the water of these currents is either of a lower or higher temperature than the adjacent sea, according to their line of approach from a warmer or a cooler climate. This difference in some places amounts to 10° Fahrenheit; and the skilful mariner may often learn from his thermometer, the probable error of his latitude by the log.

Humboldt, ascribing the formation of these currents to the rotation of the earth, calls them currents of rotation. But he does not distinguish between the proper currents and the drift-water, which latter produces a slight western current on the surface of the ocean between the tropics. This latter motion indeed is probably caused by the united effects of the rotation and the trade-winds on the wide expanded surface of the ocean. The small degree of velocity in this current, however, shows that the stronger currents near the equator cannot arise from the same cause. Rennell, the first writer who carefully distinguished the currents from the drift-water, thinks that the equatorial currents are caused by the accumulation of great masses of drift-water near the equator by the north-easterly and south-easterly trade-winds. But this opinion will be found inadmissible when it is considered that such accumulation could only produce a superficial current, and that many instances adduced by himself evidently show that these currents are not superficial, but probably reach the bottom of the sea, and certainly go to a very great depth.

The currents which flow from the higher latitudes towards the equator are supposed to have their origin in the melting of the masses of ice which encompass the poles. But if this supposition were true, these currents would cease during the winter, unless we also suppose that the melting of the ice continues to take place even during that season at a great depth beneath the surface of the sea, an assumption which in the present state of our knowledge on this subject can hardly be admitted.

If however both these opinions respecting the origin of the currents were allowed to be true, we should still have to account for the origin of other currents, in the formation of which neither the drift-water between the tropics nor the melting of snow near the poles can possibly have any share. Of such a description is the current which seems to be formed between the southern coast of Ireland and Cape Finisterre in Spain [**ATLANTIC OCEAN**], and runs along the western coast of southern Europe and northern Africa to the Bight of Benin.

CURRIE, JAMES, M.D., was born 31st May, 1756, at Kirkpatrick-Fleming, in Dumfries-shire, of which parish his father was clergyman. Being originally intended for a mercantile life, as soon as he had received the rudiments of a liberal education he went out to Virginia; but upon the breaking out of the American war in 1776 he returned home, and soon after commenced the study of medicine at the University of Edinburgh. Having completed the usual course, he took his degree of M.D. at Glasgow in 1780, and immediately proceeded to London. His intention now was to go out to Jamaica, where there appeared to be a favourable opening for the exercise of his profession; but a sudden attack of illness prevented him from sailing after he had taken his passage. On his recovery he settled and began to practise in Liverpool, in

1781. Here he soon met with great success in his profession. His first publication was a biographical memoir of a deceased friend, which was printed in the 'Transactions of the Manchester Philosophical and Literary Society' for 1785. In 1790 a paper on tetanus and convulsive disorders, which he communicated to the 3rd volume of the 'Memoirs of the London Medical Society,' considerably extended his professional reputation. In 1792 he was elected a Fellow of the Royal Society. In 1793 he published a pamphlet, under the title of 'A Letter, Commercial and Political, addressed to the Right Hon. Wm. Pitt, by Jasper Wilson, Esq.,' which attracted a good deal of attention: it was an exposure of the impolicy of the war with France. In 1797 appeared the work on which his professional reputation principally rests, entitled 'Medical Reports on the Effects of Water, cold and warm, as a remedy in Febrile Diseases.' The method of treatment here recommended by Dr. Currie, affusion in cold water in cases of fever, though a remedy not to be trusted except to the most skilful hands, has since been applied in suitable circumstances with extraordinary success. A second volume of the Reports appeared in 1804, and the author was preparing a new edition of the whole work when he died. The name of Dr. Currie is best known to general readers by his edition of the works of Robert Burns, including both his Poems and Letters, which he published for the benefit of the poet's family, in 4 vols., 8vo., in 1800. It was introduced by a criticism on the writings of Burns, and 'Some Observations on the character and condition of the Scottish Peasantry,' both of which papers were drawn up with much elegance and ability. This edition has formed the basis of every succeeding collection of the poet's works. In 1804 Dr. Currie felt his health rapidly giving way; and leaving Liverpool, he spent some time in Bath and Clifton. In March, 1805, he considered himself to be so far restored, that he took a house and commenced practising in Bath; but his illness soon returned, and he died at Sidmouth on the 31st of August in the same year. (Chalmers's *Dictionary*, from a Memoir in the *Magazines* drawn up by Dr. Aiken.)

CURRU'CA. [**BLACK-CAP; SYLVIADÆ.**]

CURSO'RIOUS, COURSER (Ornithology), a genus of birds of the order *Cursores*, Temm. established by Dr. Latham.

Generic character.—Bill as long as head; mandibles arched, and compressed towards their extremities; base depressed; tip sharp and entire; *nostrils* basal, oval, with an oblong lateral opening. First *quill* longest. *Legs* long; three front toes separated throughout; middle toe much the longest, with a serrated claw. Type, *Cursorius Isabelinus*.

Geographical distribution.—Africa seems to be the country principally inhabited by these birds, and there they are to be found generally at a distance from the sea, and in the arid inland tracts, where they run with great swiftness.

Example, *Cursorius Temminckii*, *Black-bellied Courier*, Sw. The following is Mr. Swainson's specific character and description.

'Cream-coloured brown; top of the head and breast ferruginous, nuchal collar double; the lower, with the quills and middle of the body, black; the upper and the sides of the body white. Total length from the bill to the tail eight inches; bill one inch from the gape, and half from the end of the nostrils. Legs three inches from the naked thigh to the tip of the middle toe, the claw of which is serrated internally. Tail round; the middle feathers not spotted; the two next with a black dot near the tip, which, in the next pair, is further broken into two white dots; the outer pair white.' (*Zool. Illust.* pl. 106. first series). *Locality.*—Africa (Abyssinia).

The Type, *Cursorius Isabelinus*, Meyer, Temminck, *Cursorius Europæus*, Ind. Orn., *Le Courvite*, Buff. Cream-coloured Plover, Lath. Gen. Syn. Cream-coloured Courser, Penn. Br. Zool., cream-coloured Swift-foot, Selby, has been seen in France and England, but only as an occasional visiter. Thus we find (Mont. Orn. Dict. last edit.) that one was killed in France, where it was seen to run with great swiftness; another was shot near St. Alban's in East Kent, the seat of William Hammond, Esq., on the 10th of November, 1785, and he presented the prize to Dr. Latham. Mr. Hammond first met with it on some light land; and so little fearful was it, that having no gun with him at that time, he sent for one, which did not readily go off, having been charged for some time, and, in consequence, he missed

his aim: the report frightened the bird away, but after making a turn or two, it again settled within one hundred yards of him, when he was prepared with a second shot, which killed it. He observed it to run with incredible swiftness, considering its size, and at intervals to pick something from the ground: it was so bold as to render it difficult to make it rise in order to take a more secure aim on the wing. The note was unlike that of any known bird. Colonel Montagu says that one was shot in North Wales in the year 1793, and preserved in the collection of the late Professor Sibthorp at Oxford. Mr. Atkinson, author of 'The Compendium of Ornithology,' was also in possession of a specimen shot at Netherby, in April, 1816.

Another of these birds was taken in Austria; and the young bird in the Darmstadt Museum, alluded to by M. Temminck, was probably killed in Europe. Mr. Fox (*Zool. Journal*, vol. iii., p. 492) records the death of one shot on the 15th October, 1827, under Timberwood Hill, in Charnwood Forest, Leicestershire, by a tenant of Mr. T. Gisborne's. He described it as coming flying over his head, uttering a cry with which he was unacquainted, and it settled near him. Some idea of the enormous prices which were at one time given by collectors for rare birds killed in Britain, may be formed from the sum which Dr. Latham's specimen produced: Mr. Fox says it was purchased for eighty-three guineas.

[Cursorius Temminckii.]

C. Bonaparte, Prince of Musignano (*Specchio comparativo*) places the form in the family Pressirostres of the order Grallæ, between *Otis* and *Ædicnemus*.

CURTATE (shortened), a term sometimes applied in geometry or astronomy to a line projected orthographically upon a plane. [PROJECTION.]

CURTEIN, or CURTANA, the name given to the first or pointless sword, carried before the kings of England at their coronation; also called the sword of King Edward the Confessor. It is mentioned by both these names in Matthew Paris, under the year 1236, when detailing the marriage ceremonial of Henry III. In antient times it was the privilege of the earls of Chester to bear this sword before the king, which, in an emblematical form, is considered as the sword of mercy.

CURVATURE, a mathematical term expressive of the comparative degree of bending which takes place near the different points of a curve. If we imagine a point to describe a curve, to be continually changing the direction of its motion, it may change this direction either more or less rapidly, that is, describe a line which is more or less curved. As in the article CONTACT, we shall first take a rough method of illustration grounded on the notions we derive from experience, and show how the accuracy of mathematics is introduced into the definition. We must suppose the reader to have gained the ideas which are introduced in the articles DIRECTION and VELOCITY.

Two points, A and a, are describing two curves, the

directions of motion at A and a being AT and at. That the first curve is more curved than the second, we may easily see; and if we wished to give some notion of the comparative degree of curvature, we might proceed as follows. Measure off equal arcs AB and ab (remember this equality throughout), say of one inch each; ascertain the direction BV and bv, from which A and a are proceeding when they arrive at B and b, and measure the angles BVT and bvt. If we find the first to be twice as great as the second, then the phenomenon by which we recognize curvature (change of direction) is twice as great in the first as in the second. Hence we say that the curvature of the first is twice as great as that of the second.

But here arises a difficulty of the same kind as that explained in VELOCITY. The preceding ratio of two to one is that of the whole effects of curvature from A to B, and from a to b. If the change of direction were uniform, that is, if every tenth (or other) part of AB gave a tenth (or other) part of the change of direction, it would then be indifferent whether we chose an inch for AB and ab, or any other length. But if the curvature vary unequally, the comparison of the united effects of all the curvatures from A to B, and from a to b, does not give a proper ratio of the comparative curvatures at A and a. The only curve in which this is the case is the circle, which is the curve of uniform curvature, just as the straight line is the line of uniform direction. But we immediately perceive that if AB and ab had each been the hundredth part of an inch instead of an inch, this objection would have held in a less degree; if the thousandth part of an inch, still less, and so on. Hence, as in VELOCITY, it is not by the proportion of the angles BVT and bvt that we get an exact and unalterable notion of what is taking place at A and a, but by the limit to which that proportion approaches, as B and b move back towards A and a, and the angles in question diminish without limit. This is the accurate terminal notion on which the mathematical theory of curvature is founded.

If the two curves had been circles (or curves of uniform curvature) it is found that the limit of the proportion of these angles (or the proportion of the angles themselves, which for circles is the same as its limit) is inversely as the radii of the circles; that is, doubling the radius of a circle halves its curvature, and so on. This suggests an absolute measure of the curvature at A. Let the second curve be a circle, so taken that BVT and bvt shall have a limiting proportion of 1 to 1, or shall continually approximate to equality (EQUALITY, APPROACH TO). The circle ab has then at a the same curvature as the curve at A, and its radius (called the radius of curvature) being determined, the degree of curvature at A is known, as compared with that of any point of any other curve whose radius of curvature is known. This radius of curvature is thus determined: Draw the perpendicular BK and the chord AB. Then if the chord AB be always represented by the fraction c of an inch, and BK by k of an inch, the limit towards which $c \times c \div k$ approaches, as B is made to approach towards A, is the diameter of the circle of the curvature, or double of its radius. Or if through A and B a circle be always conceived to pass, which touches both AV and VB at A and B, the limiting position of that circle is the circle of curvature.

If the curve be referred to rectangular coordinates, and if x and y be those of the point A, $y = \phi x$ the equation of the curve, and ϕ' and ϕ'' the first and second differential coefficients of ϕx , then

$$\text{Radius of curvature at A is } \frac{(1 + \phi'^2)^{\frac{3}{2}}}{\phi''}$$

If ϕ be the angle made by the tangent with the axis of x , and s the arc from any given point to A ,

$$\text{Rad. of Curv. at } A \text{ is } \frac{ds}{d\phi}$$

On this subject see INVOLUTE, EVOLUTE.

When the curve is not a plane curve, imagine it orthographically projected upon a plane. Its change of direction is then partly parallel to the plane, partly perpendicular to it, and the curve is said to have *double curvature*. But as this subject, together with that of the curvature of surfaces, is not of an elementary character, we shall not proceed further here, but refer to SURFACES, and to all works which treat largely of the Differential Calculus.

The circle of curvature is also the circle of contact, or the nearest circle which can be drawn to the curve, just as the straight line of direction is also the line of contact, or the tangent. An infinite number of circles can be made to present the appearance of touching the curve at A , [CONTACT] of all of which the circle of curvature comes the closest. Moreover, it always cuts the curve which it also touches (in the mathematical sense), except only at particular points. That is to say, the circle of curvature has in general a contact of the second order with its curve, in which case the circle always passes through the curve. But if at any particular point the contact should be of a higher and odd order, the circle of curvature does not pass through the curve.

CURVE, and CURVES, THEORY OF. A curve is a line which has *curvature*. Though the second of these terms be derived from the first, yet it is the notion explained in the preceding article which is preliminary to the explanation of the general term *curve*. Let a point move with a perfectly gradual change of direction, and it describes a curve.

Curves are said to be of the same species, in which the motion of the describing point is regulated by the same mathematical law. Thus the general law of the circle is, that all its points are equidistant from a given point. This law is the characteristic of the species; one circle is distinguished from another by the length of the constant distance supposed in the law of formation.

And in like manner as 0, or nothing, is classed under the general name of number or quantity, so the straight line itself (or the line without curvature) is, in algebra, spoken of under the general term *curve*. Or, in the last-mentioned science, the word means any line which is described by a point moving under one and the same law through every part of space which is consistent with the law.

The connexion of algebra with the doctrine of curves depends upon the method of coordinates (ABSCISSA, ORDINATE, COORDINATES), by means of which every algebraical function whatsoever is connected with the properties of a curve. This is the point of greatest utility in the theory, namely, the power which it gives of representing to the eye all the varieties of magnitude which an algebraical function undergoes, while one of its letters passes through every state of numerical magnitude.

The number of curves which have received distinct names, out of the infinite number which may be drawn, is very small; we subjoin the names of those which are of most usual occurrence, referring to the several articles for further information.

TANGENTS, &c., CURVES OF.]	
1. Circle	19. Exponential or Logarithmic Curve
2. Ellipse	20. Spiral of Archimedes
3. Hyperbola	21. Logarithmic Spiral or Equiangular Spiral
4. Parabola	22. Reciprocal Spiral
5. Semi-cubical Parabola	23. Lituus
6. Cissoid of Diocles	24. Quadratrix of Dinostratus
7. Conchoid of Nicomedes	25. ——— of Tschirnhausen
8. Trisectrix	26. Catenary
9. Lemniscata	27. Tractory
10. Cycloid	28. Syntactory
11. Companion of the Cycloid	29. Tractrix
12. Harmonic Curve	30. Ovals of Cassini
13. Trochoid	31. Watts's Parallel motion curve
14. Epicycloid and } Trochoidal	
Cardioid	
15. Hypocycloid	
16. Epitrochoid	
17. Hypotrochoid	
18. Curve of sines, cosines, tangents, &c. [SINES,	

The general characteristics of curves are extremely varied, and very few of them have received names. We subjoin a diagram, which will show all the varieties of figure most commonly considered in works on the Differential Calculus, premising however that we do not actually know any curve which contains them all. It would appear as if our figure contained several curves, but it must be remembered that in the algebraical sense many curves exist with branches completely unconnected, but all described under one law.

The several parts of the preceding are of continual occurrence; the following are the names and references:

(1). Points of inflexion or contrary flexure (FLEXURE, CONTRARY).

(2). MULTIPLE POINTS, double, triple, &c. according to the number of times the curve passes through them.

(3). CUSPS: the terms are hardly sufficiently well settled to enable us to say whether the 3* is to be considered a double point, a triple point, or not a multiple point at all.

(4). It is customary to call any part of the curve which encloses space an OVAL, though, according to the common meaning of the term, there is no oval in our diagram except 4†. Of 4* we hardly know whether it would be called an oval or not.

(5). Conjugate points [CONJUGATE]; when of a general law of description which gives ovals, a particular case is taken in which an oval disappears, it generally leaves behind it, so to speak, a single point which is included under the equation to the curve, but has no contiguous points. We should propose to call these points *evanescent ovals*, and shall give some instances in the article OVAL. [INVOLUTE, EVOLUTE, CAUSTIC, CONTACT, TANGENT, ARC, AREA, ASYMPTOTE, MAXIMA and MINIMA, &c.]

CURZOLA, or CORZOLA (formerly Corecra, Strabo, p. 315), an island in the Adriatic, comprised in the circle of Ragusa and in the Austrian kingdom of Dalmatia. The channel of Curzola separates it from the peninsula of Sabinello. Including the adjacent islets of Agosta and Torcola, the area is about 231 square miles. Curzola contains one town, a market-town, and about 6500 inhabitants. The surface is chiefly occupied by woods and forests, which furnish good ship-timber; the vineyards annually yield about 80,000 hogsheads of wine, and the fisheries on the coast are productive; but little grain is raised, and the fresh water is scarcely usable. Curzola, the chief town, is situated on a neck of land upon the channel (here called canal), in 42° 57' N. lat. and 16° 50' E. long.; it is surrounded by walls, and has a cathedral, two monasteries, about 800 houses, and 1800 inhabitants. It is the seat of a bishopric, builds vessels, and traffics with the produce of the island.

CUSCUTA/CEÆ, a small natural order of monopetalous exogens, cut off from Convolvulaceæ because of their imbricate corolla, which does not fall off after flowering, their seeds with a spiral acotyledonous embryo, and their leafless parasitical habit. Cuscuta, or Dodder, is a genus met with in most temperate climates, the species fixing themselves on the branches of woody or other plants, twisting round them, striking a number of minute suckers down upon their bark, and thus attracting from the system of the plants and from the air, the sustenance necessary to their own support. Hence they are true parasites although they do not actually, like miseltoe, plunge their roots into the wood and incorporate themselves with the tissue.

Common Dodder, *Cuscuta europæa*, is a white or reddish-looking annual, which flings its thread-shaped arms like a cluster of living threads round the branches of heath, furze,

[*Cuscuta minor*, twining round Lucerne.]

1, a perfect flower; 2, a corolla cut open; 3, an ovary with its calyx; 4, the embryo.

&c., on commons and dry wastes. It has no leaves, except tiny scales that stand in their room; and it bears small clusters of white bell-shaped blossoms, each of which has five scales at the base of its tube. The fruit is a little membranous capsule, opening transversely like a soap-box, and dropping four seeds upon the soil. There is a common prejudice that these seeds actually strike root into the plant; but that this is a popular error is sufficiently shown by the following observations translated from De Candolle: 'The seed of Dodder differs from that of other Convolvulaceæ by the absence of cotyledons, as the Dodder itself differs from them by the absence of leaves; the latter are either entirely absent, or are reduced to almost imperceptible scales. The germination of the Dodder is effected, like that of plants in general, in the earth, and without requiring the presence of other vegetables. The embryo, deprived of its cotyledons, is nourished, in its first development, at the expense of the central albumen which it envelopes. The slender and simple radicle descends into the earth; and the plumule, equally simple and cylindrical, rises like a thread: if it finds no other living plant near it, it dies; if it finds one, it surrounds the stem, and from the points of contact proceed hollow tubercles or suckers which plant themselves in the bark, and suck the juice which has been elaborated by the plant attacked; then the root becomes obliterated and dies, and the plant lives from that time forward by its suckers only. Whilst it was not a parasite, it rose vertically; as soon as it became one, it was no longer tempted to direct itself either vertically, or towards the light. Its shoots dart from one plant to the other, and thus are conveyed to new victims when the old ones are exhausted. Often the seeds germinate before they quit the capsules, and the new plant immediately becomes a parasite; this is particularly observed in the *Cuscuta monogyna*, which attacks the vines in Languedoc.

'The Didders, called by the French cultivators *teigne*, *rache*, *perruque*, &c., are very dangerous to the fields of leguminous plants which they attack, and upon which they multiply themselves with singular rapidity. They destroy the plants either by depriving them of their nourishment, or by strangling them in their folds. It is difficult to guard against them on account of the rapidity of their vegetation, the facility with which they pass from one plant to another, the abundance of their seeds, and the double power which they possess of germinating either in the earth or in the capsule. M. Vaucher cleared his artificial fields from dodder pretty well by perpetually breaking and dividing their stalks with a rake. The means which appears to me really efficacious are immediately to mow all the portions of artificial meadow where Dodder has been seen to develop itself, and to do it before it can have produced seed. If it appear in fields of flax, the plants attacked must be cut down, or rooted up; and if it appear among vines, the branches must be cut before the seed is matured. If these precautions have been neglected,

and a portion of the land should be infested with these seeds, the crop which has been attacked must be replaced by crops of corn or of grasses. Thus time is given to the seeds of Dodder which have been concealed in the soil, to develop themselves, when they may perish without doing any harm, since the soil finds itself covered with plants which cannot nourish them. As to the seeds of leguminous plants which may be infested by a mixture with those of the Dodder, the best means to get rid of them is to sift them in a tolerably fine sieve, so that the seeds of the Dodder, which are very small, may pass through, leaving those of the trefoil or of the lucerne. In this operation the seed must be shaken rather violently, so as to break the capsules of the Dodder, and to force their seeds out.'

CUSP (*Cuspis*, a pointed end), a mathematical term used where two branches of the same or different curves appear to end in a point. Thus, in an eclipse of the sun, the borders of the sun and moon make two cusps at their point of intersection.

In the theory of curves, the cusps which appear are always such that the two branches have a common tangent at the cusp, and they are distinguished into the cases in which the tangent lies between the branches or on one side of both.

In the actual determination of the position of cusps by means of ordinates to a given axis, there are two distinct ways of proceeding.

1. For cusps whose tangent is perpendicular to the given axis.

2. For cusps whose tangent is not perpendicular to the axis.

The first case ought in part to fall under the theory of maxima and minima; ϕx being the ordinate, it is the case where $\phi'x$, the differential coefficient, becomes infinite and changes sign; or becomes infinite and afterwards impossible, having previously had two values of the same sign for each value of x . These cases give cusps of the first and second kinds, as shown in the two diagrams.

All other cusps (namely, those whose tangents are oblique or parallel to the axis) are found by observing the points at which $\phi''x$, the second differential coefficient, takes the form A , having previously had that of $A \pm B$; that is, in $\phi''x$, the points must be found at which a term of double value vanishes and then becomes impossible. If for points immediately preceding, the $A+B$ and $A-B$ were of different signs, the cusp is of the first species; if of the same sign, of the second species. It would be useless to attempt separation of the theory of cusps from the general theory of curves, further than is contained by the preceding rules.

CUSP, a term given by Sir James Hall, in his 'Essay on the Origin of Gothic Architecture,' and now commonly applied to the points terminating the internal curves of the trefoiled, cinquefoiled, &c. heads of pointed arch windows.

CUSSET, a town in France, in the department of Allier, on the little river Sichon (which flows into the Allier on its right or east bank), and close to Vichy, on the Allier, a town much frequented on account of its mineral waters. Cusset is about 215 miles from Paris by the road through Fontainebleau, Montargis, Nevers, and Moulins, in $46^{\circ} 8'$ N. lat., and $3^{\circ} 27'$ E. long.

This town owes its origin to a Benedictine nunnery, established here during the reign of Charles le Gros, A. D. 886, by Emmène, bishop of Nevers, and raised to the rank of an abbey, A. D. 1236, by Hugues, bishop of Clermont, who established at Cusset, the same year, a collegiate church. There was also, before the Revolution, a convent of Capuchin monks just out of the town. Cusset is surrounded with walls, and is in a country fertile in wine, fruit, excellent hemp, and especially in all kinds of grain. There is a coal-pit near the town. The inhabitants in 1832 were 3740 for the town, or 4910 for the whole commune. There is a large paper-mill, in which 100 workmen are employed.

CUSTARD APPLE, a name given in the West Indies to the fruit of *Anona reticulata*. [ANONACEÆ.]

CUSTOM-HOUSE, the building in which the business is conducted of collecting that part of the public revenue which is derived from duties charged upon the importation or exportation of merchandise. In common parlance, the term custom-house has a more extensive signification, and is understood to embrace the establishment by means of which that branch of the public revenue is collected and its regulations are enforced.

CUSTOMS, or USAGES, in law (consuetudines), are either general or local. The first kind consists of those usages which having prevailed throughout England from time immemorial, but, without their original institution having been handed down to us in records or writing, have been recognized by judicial decision*, and form that common law, or *lex non scripta*, which is the chief foundation of English jurisprudence. To like immemorial usage is to be ascribed the existence of such parts of the civil and canon laws, as from the earliest times have formed the rule in the king's ecclesiastical, military, and admiralty tribunals, and also in the courts of the two English universities. These laws of foreign origin subsist however only as inferior branches of the customary law, subject to the superintendence and control of their proceedings by the superior temporal courts, and to a strict observance of the rules of construction assigned by these last to the statute law.

These general customs of the realm, which form the common law, properly so called, alone warrant the existence and jurisdiction of the king's superior courts; and can only be drawn into question there. These general customs, as originally methodized by the Saxon kings, and in some cases modified in the early Norman reigns, supplied those fundamental rules by which, in cases not provided for by express enactment, the course of inheritances, the interpretation of acts of parliament, and most of the remedies for civil and criminal injuries are regulated. Numerous axioms essential to the administration of common justice have no other binding force than antient and uninterrupted usage, which has obtained the force of law by the recognition of the courts. [COMMON LAW.]

Among these general customs must be enumerated those laws which govern the particular bodies of men to which they relate; merchants, innkeepers, carriers, owners of lands adjoining the sea coast, &c. &c., as well as the inhabitants of particular counties or boroughs, in the particular instances of gavelkind and Borough English. That custom called the law of the road, by which riders and drivers are expected to keep the left hand, as well as that respecting servants hired at yearly wages, by which either master or servant may determine the contract at a month's warning, or on paying a month's wages, have been recognized by the courts from time to time as parts of the common law. These, like the rest, originated in general convenience, and being gradually drawn more into notice by frequent recurrence, have been finally sanctioned by judicial authority. For immemorial customs may be extended to things and circumstances which arise at the present times. Thus a custom from time immemorial that all officers of a court of justice shall be exempt from serving other offices includes offices created within the time of legal memory, but cannot be enlarged beyond the extent to which the use has been carried; for that, and not the reason of the thing, determines the courts in declaring what the law is in such cases.

The customs by which the king's superior courts of Westminster Hall regulate their administration of justice, are popularly termed their practice. These rules are founded on antient usage, and, in respect of their universality, form a part of the common law without its being necessary to allege custom or prescription to warrant them.

Where a custom is already part of the common law, the superior courts will take judicial notice of its existence as such, without requiring it to be stated in the written pleadings. Thus each of these tribunals will take judicial notice of its own customs or practice as well as of that of the rest; whereas the practice of inferior courts, as well as particular or local customs, extending to certain persons or districts only, being therefore different from and contrary to the

common law, must, with the exception of gavelkind and Borough English, be set forth with due precision.

This, though an observation apparently technical only, forms in its application the test by which we distinguish general from the local or particular customs just described. These latter customs must necessarily have had their origin in the peculiar wants of their respective districts, and are the remains of that multitude of similar usages from which Alfred and his Saxon successors collected those laws which may be considered as forming the common law of the nation at the time.

Many of these customs, for reasons now forgotten, were permitted to remain in some counties, cities, and manors, &c., in their former vigour, though at variance with the laws of the rest of the nation, and are confirmed by Magna Charta and other acts of parliament. Such are the customs of gavelkind (abolished in Wales by stat. Henry VIII.), by which all the sons inherit alike, of Borough English, by which lands held in burgage tenure descend to the youngest, instead of the eldest son; and of some boroughs, that widows shall have dower of all, instead of a third of their husband's lands. A more striking instance is that custom in many cities and towns to hold courts for trial of causes without royal grant. The particular customs of manors as to descent, &c., are also of this kind, and bind the copyhold and customary tenants. The existence of every such local custom, with the exceptions above noticed, as well as its application in each particular case, must be alleged in the pleadings, and proved, like any other fact, before a jury: sometimes they are open to evidence without being pleaded. Under no circumstances can these questions be entertained by an ecclesiastical court without the consent of the party impugning the custom.

Such customs of London as do not concern the property of the corporate body itself are proved by a peculiar mode, that of a certificate to the superior courts of law from the lord mayor and aldermen, conveyed by the mouth of their recorder in a solemn ceremonial; without this certificate these courts will not take judicial notice of them.

A particular custom to be valid must have been used 'from time whereof the memory of man runneth not to the contrary.' This is 'prescription,' or 'title by prescription;' and more accurately describes what is commonly called 'time immemorial,' which means, says Littleton, 'that no living witness hath heard any proof or had any knowledge to the contrary,' and as lord Coke adds, 'that there is no proof by record or writing or otherwise to the contrary.' It has been doubted whether a prescription (in its proper sense) and a custom can coexist. There is some curious learning on this point collected in the arguments and judgment in *Blewett v. Tregoning*, 3 Ad. and Ellis. It was held that a custom in a particular market that every pound of butter sold in it should weigh 18 oz. was bad, being directly contrary to a statute of Charles II., which enacted that every pound avoirdupois throughout the kingdom should weigh 16 oz. only. The right to a particular custom must have been continued within time of memory peaceably and without lawful interruption, and will not be lost by mere disuse for ten or twenty years; though in such case to establish it by proof becomes more difficult. But it cannot stand against an express act of parliament to the contrary, for that itself proves a time when the right to such a custom could not exist. It must also be so far reasonable, according to the standard warranted by authority of law, that though no particular origin can now be assigned for it, or though the state of things in which it is known to have arisen has been altered, no good legal reason can be given against its continuance. If it may have had a legal and reasonable origin, it shall be presumed that it actually had it; and its varying from the general law forms no objection, for that is the very essence of a particular custom; but if it be so contrary to any known rule or principle of law, or to the good of the public, or of a multitude of persons, that it cannot be presumed to have had a reasonable commencement in voluntary agreement for some beneficial object, as for securing possessions, promoting trade, or suppressing fraud, it will be void. Thus no length of usage would render good a custom of the secretary of state's office to issue warrants in general terms against the authors, printers, and publishers of a libel, without naming them; that course being contrary to clear and well-settled principles of law, which will not suffer a mere officer to decide on the individuals to be imprisoned. Again,

* Bracton's definition of a custom is this—'Consuetudo vero quandoque pro lege observatur, in partibus ubi fuerit more utentium approbata, et vicem legis obtinet. longevi enim temporis usus et consuetudinis non est vilis auctoritas.' (Bracton, fol. ii., ed. Lond. 1569.) This is no inapt definition of a custom observed as if it were law, by those who find it convenient and reasonable; but we can hardly conclude from this passage that this excellent old writer clearly saw that custom could not be law till made so by the sovereign power, or those to whom the sovereign power has delegated parts of its authority.

a custom in an inferior court to try causes by six jurors was held bad, as contrary to the common law, though saved in Wales in some instances by a statute of Henry VIII., confirming such custom where it then existed. But long usage and acquiescence in one uniform payment, or in exempting persons particularly situated from contributing to it, are cogent evidence that it is reasonable; for as Lord Mansfield once said, it cannot be presumed that during a long period of years one half the parties were knaves in wrongfully receiving that to which they were not entitled, and the other fools for submitting to an unjust demand. It belongs to the judges of the courts to decide on what is reasonable when brought judicially before them.

Where a custom is harmless in itself, and affords recreation to a number of persons, though to the temporary inconvenience of an individual, it will be upheld and referred to a legal origin. Thus a custom for the inhabitants of a parish to play at cricket, or dance on private property in the parish, was held good, as the lord might have annexed this condition to his original grant of the land. A custom must also be certain as to the description of parties benefited, and compulsory, without its depending on the caprice of any third person whether it can be acted on or not. It must also be consistent; for repugnancy to any other local custom would be plainly contrary to that origin in common consent on which alone it stands: and lastly, it must be strictly pursued, being derogatory of the common law.

Local custom varies from prescription in this: the former is alleged in legal forms as existing not in any person certain, but within a certain named district, without showing any legal cause or consideration for it; whereas prescription must have a presumed legal origin, and is either a personal right, always claimed in the name of a person certain and his ancestors, or those whose estate he has, or by a body politic and their predecessors, or else is in a *que* estate; viz., a right attached to the ownership of a particular estate, and only exercisable by those who are seised of it. All customs of cities, towns, and boroughs, by which persons not freemen were prevented from keeping shops or using trades or handicrafts within them, were abolished by 5 & 6 William IV., cap. 76, sec. 14. [PRESCRIPTION.]

Customs of traders, or seamen, as also of agriculture, mining, &c., will be followed in the construction of contracts, unless they are inconsistent with their express terms, and, subject to that condition, they are admissible even to annex incidents to them as to which they are silent. The 'custom of the country' means the custom of all parts of the country to which it can in its nature be applied. Thus a custom that land accruing imperceptibly to the sea-shore belongs to the owners of the shore, applies to all such parts of the realm as adjoin the sea, unless limited in terms to a particular district.

The immemoriality of a particular local custom may be sufficiently proved by living witnesses attesting regular existence for twenty years, unless contradicted by contrary proof. Upon this doctrine will be found to depend a great variety of public as well as private rights to antient offices, estrays, treasure trove, wreck, nomination of juries, &c.; as well as to tolls of markets, port duties, tithes, antient rents, &c., and to exemptions from those burdens. The numerical amount of instances in which the privilege claimed can be proved to have existed must be considerable or not according to the frequency or the rarity with which they may be naturally expected to recur. Thus in a copyhold custom of surrendering in fee so as to bar an entail, a single instance of user, though incapable of making a custom, is evidence sufficient to support it, if not unreasonable in itself.

Reiterated facts of user make a custom of trade; but the mere opinion of merchants is not sufficient for that purpose; nor can any course of action pursued under colour of a custom of merchants alter a general rule of common law when established by judicial decisions.

A long continued usage for exempting particular persons from a local burden, will, if necessary, be supported by presuming that it originated in an act of parliament now lost, though no length of usage will countervail the terms of a statute to the contrary.

CUSTOMS-DUTIES consist for the most part of taxes levied upon goods and produce brought for consumption from foreign countries; such duties are sometimes collected upon exports made to foreign countries, and upon goods and produce passing from one port to another of the same

country. Of this nature were the duties on coals, slate, and stone, carried coastwise from one port in the United Kingdom to another, which duties were repealed in 1831. With the exception of a small-rated export duty upon coals, hare-skins, rabbit-skins, and sheep's wool, and an *ad valorem* duty of one-half per cent. on the shipment to foreign countries of some articles of British production, the whole customs-revenue of this kingdom is now derived from duties charged upon the importation for consumption of foreign and colonial merchandise.

The earliest statute passed in this country, whereby the crown was authorized to levy customs-duties, was the 3rd of Edward I. The mode long employed in the collection of these duties was to affix a certain rate or value upon each kind or article of merchandise, and to grant what was called a *subsidy* upon these rates. This subsidy was generally one shilling of duty for every twenty shillings of value assigned in the book of rates. The early acts granting these duties speak of them as subsidies of tonnage and poundage. The word tonnage was applied to a specific duty charged on the importation of each tun of wine and the exportation of each tun of beer; and the word poundage was applied to other articles valued as already explained.

The first 'book of rates agreed upon by the House of Commons,' is believed to be that compiled by a committee in 1642, during the reign of Charles I., and published under the authority of the House by Lawrence Blaiklock. The next book of rates of which we have any record, was also published by order of the House of Commons in 1660, the year of the restoration of Charles II. In the fifteenth and twenty-second years of the reign of that king, the principle of poundage was altered as respected some articles, and upon those articles specific duties were charged instead, though the system was still followed with regard to the great bulk of articles. But in the reigns of William III. and Anne many additional specific rates were imposed, in place of the valuation for the subsidy. This course of substitution was continued from time to time, and some other innovations were adopted by which the simplicity of the antient plan was destroyed; so that in a work of authority, published by Mr. Henry Saxby, of the Custom-House, London, in 1757, we find as many as thirty-nine principal branches of customs-duties, with subdivisions applying to different kinds of goods, thereby introducing a degree of complication into the subject which must have caused great embarrassment to traders.

The difficulties here mentioned were increased by the great number of acts of parliament passed from year to year for altering the duties or regulations of this branch of the revenue; and the great bulk and intricacy of the customs-laws had caused such inconvenience that about the year 1810 the lords of the Treasury employed Mr. Jickling to prepare a digest of those laws. Five years were employed in completing this task, and some idea may be formed of the laborious nature of the work, and of the necessity for its performance, from the fact that the digest forms a large octavo volume of 1375 pages. The work is intituled 'A Digest of the Laws of the Customs, comprising a Summary of the Statutes in force from the earliest period to the 53rd George III. inclusive.' The effect of the numerous fresh enactments to impair the usefulness of this exposition of the revenue laws was very soon apparent, and in 1823, Mr. Hume, the secretary of the Board of Trade, then comptroller of the Customs in the port of London, was appointed by the Treasury 'to undertake the preparation of a general law or set of laws for the consolidation of the Customs of the United Kingdom.' In the performance of this duty, Mr. Hume prepared 11 bills under the following heads:—

An Act	for the Management of the Customs,	6 George IV., cap. 106.
"	for the general Regulation of the Customs,	" " 107.
"	for the Prevention of Smuggling,	" " 108.
"	for the Encouragement of British Shipping and Navigation,	" " 109.
"	for the Registering of British Vessels,	" " 110.
"	for granting Duties of Customs,	" " 111.
"	for the Warehousing of Goods,	" " 112.
"	to grant certain Bounties and Allowances of Customs,	" " 113.
"	to regulate the Trade of the British Possessions abroad,	" " 114.
"	for regulating the Trade of the Isle of Man,	" " 115.
"	for regulating Vessels carrying Passengers to foreign Parts,	" " 116.

These several acts received the royal assent in July, 1825, and were respectively brought into operation on the

1st January, 1826. In their effect they have rendered the greatest benefit to the commerce and the revenue of the country, by substituting simplicity for complexity, and certainty for the conflicting opinions and varying practice of those by whom the previous statutes were practically administered. The number of those statutes, many of which were obsolete, that were repealed by the first of these 11 acts, amounted to 443. Many subsequent acts affecting the customs-revenue have certainly been passed, but the whole customs-laws of this country now in force are contained in one moderately sized octavo volume, in which the subject appears cleared from all complexity.

The amount of customs-duties collected in the United Kingdom during each of the last ten years has been as follows:—

1827 .	£21,009,052	1832 .	£19,684,574
1828 .	20,608,710	1833 .	18,575,182
1829 .	20,571,837	1834 .	21,118,920
1830 .	21,084,524	1835 .	22,990,877
1831 .	19,645,939	1836 .	23,796,622

The great bulk of this revenue is collected from a very small number of articles. Upon six of these, viz., spirits, sugar, tea, timber, tobacco, and wine, the amount collected in 1836 exceeded 19 millions, and 22 out of 23½ millions in the same year was afforded by 17 articles, the least important of which furnished 102,108*l.* to the revenue. The eleven articles which, with the six already enumerated, make up the 22 millions of duty, are butter, cheese, coffee, currants, raisins, molasses, seeds, silk manufactures, tallow, cotton, and sheep's wool. The remaining amount, less than two millions, is levied upon a long list comprising several hundred articles of merchandise, as to a large proportion of which the disadvantage to the foreign trade of the country must be out of all proportion greater than the benefit yielded to the revenue.

CÜSTRIN, one of the eighteen circles into which the government of Frankfort, in the Prussian province of Brandenburg, is divided. Its area is about 294 square miles, and it contains about 40,800 inhabitants; an increase of 11,900 since the year 1817. It lies on each side of the Oder, into which the Warthe flows at Cüstrin. The western parts are wholly composed of marsh land and swamps, and contain the 'Oderbruck,' or swamp of the Oder: the eastern parts are at a greater elevation, and are well wooded. The principal employment of the inhabitants is cattle-breeding; the circle, however, grows corn enough for its consumption, besides flax, hops, and tobacco.

CÜSTRIN, the capital of the circle, in 52° 35' N. lat. and 14° 40' E. long., is a strong fortress placed at the confluence of the Warthe with the Oder, and encompassed on all sides by marshes and water. The first fortifications were constructed by John, Margrave of Brandenburg, in 1568: it fell into the hands of the Swedes in 1631. All but three houses were destroyed in a bombardment by the Russians, of eight days only, in August, 1758; it surrendered unconditionally to the French, November 1, 1806, and was given up by them, March 1, 1814. The town itself and its fortifications are of small extent; but without them it comprises the new town, the intrenchments on the left bank of the Oder, which is connected with the new town by a wooden bridge 875 feet long, and a long suburb running along the right bank of the Oder, as well as two smaller suburbs. Cüstrin has two Protestant churches, a gymnasium, hospital, and bridewell; about 600 houses, and 5600 inhabitants. The manufactures consist of woollens, stockings, starch, brandy, and beer. Much grain and cattle are sold, but the vicinity of Frankfort renders its external trade comparatively insignificant.

CUTCH, a principality lying between 22° and 25° N. lat. and between 68° and 72° E. long. It is bounded on the north by the Great Sandy Desert, on the east and the south by the Gulf of Cutch, and on the west by the Koree or eastern outlet of the Indus. The country is naturally divided into two portions, of which that towards the south is an irregular hilly tract; the northern part, called *The Runn*, is an extensive salt morass, 160 miles long from east to west, and varying in breadth from 4 to 60 miles. During the rainy season the Runn is completely covered with water, and the country to the south is quite insulated. During the dry monsoon the waters retire, and the Runn assumes a diversified appearance. In some parts it is still an impassable salt swamp; in other parts there

are great banks of dry unproductive sand, covered occasionally with saline incrustations, while other parts afford tolerable pasture. During the rainy season, the Runn can be traversed with difficulty, and only in certain parts, by horsemen.

The soil of the habitable part of the country is for the most part clay, covered with about five inches of deep sand. Towards the east the soil is loamy, and near the hills the surface is covered with volcanic matter, and abounds with specimens of metallic scoria. A range of hills, named the Lakhi, running east and west through the centre of this part of Cutch, divides it into two nearly equal portions. These hills are one continuous mass of rock, destitute of soil and of water, except during the rainy season, when the water forms channels for itself, through which it rushes to the plain on each side. A high bank of sand extends along the shore the whole distance from the Indus to the Gulf of Cutch. But little wood is found in the principality. A few common trees have been planted about the villages, and among them are date-trees, which yield fruit of good quality. The cultivation of cotton is carried on extensively, and the produce exported in return for grain, of which a sufficiency is not grown for consumption, and which is procured from Gujerat and Sinde. Iron ore occurs generally throughout the country, and in most parts coal is found in abundance. Great expectations were at one time formed as to the advantages to be derived from the coal, but the quality has not proved such as to encourage the expense of creating mining establishments. A mine situated about three miles from Bhooj was worked experimentally by order of the Bombay government in 1826, but was soon abandoned. The coal that was worked lay in two seams, each seven inches thick, and about twelve inches apart. Another mine was opened in 1828 at Seesaghud, about 19 miles from Mandavee, where also there were found two veins, the upper one only a few inches in thickness, and the other 13 inches thick.

The horses of Cutch are much esteemed; the oxen are of a very inferior description. Goats and sheep are very numerous. The wool of the latter is of long staple but coarse, answering well for the manufacture of blankets and carpeting: the weight of the fleece averages from four and a half to five pounds. Coarse woollen cloths are made and used by the inhabitants. Towards the north, and near the Runn, wild asses are very numerous, and are met with in herds of sixty or seventy together. This animal is larger and stronger than the tame ass. It is fierce and untamable in its nature, and when unable to procure pasturage in the desert lands, advances into the inclosed country, and does much damage to the grain crops: the flesh is said to be good eating.

The principal towns of Cutch are, Anjar [ANJAR], Bhooj, the modern capital, Luckput Bunder, Mandavee, Rohur, and Tahrah. Bhooj was founded about 200 years ago by Rao Bharra: it stands on the south-west side of a hill, in 23° 18' N. lat. and 69° 50' E. long. The fortifications are extensive, but being badly planned afford little protection to the place. The town has a handsome appearance from a distance; it contains several mosques and pagodas of white masonry, interspersed with plantations of date-trees, but on a nearer approach there are found to be a large proportion of mean dwellings. The palace of the rao is a large and well-built structure, covered with a kind of white enamel, which gives it a very handsome appearance. The population amounted, in 1818, to 20,000, among whom were many ingenious goldsmiths and jewellers. Luckput Bunder, formerly called Bustabunder, but which obtained its present name in 1793, when the fort of Luckput was built, stands near the east side of the Koree, in 23° 47' N. lat., and 68° 56' E. long., 75 miles north-west from Bhooj. The town is built on the brow of a hill, which rises from a swampy plain; it contains only about 2000 inhabitants, and is principally important as being on the high road from Bhooj and Mandavee into Sinde. Previous to the great earthquake of 1819, the communication from this town to the head of the æstuary of the Korée was by means of a small shallow creek, navigable only by small boats, but the effect of this convulsion was to deepen the water to eighteen feet, and effectually to open the navigation; it is however not a place of much trade.

Mandavee, the principal sea-port of Cutch, is situated on the shore of the Indian Ocean on the north side of the entrance to the Gulf of Cutch, in 22° 51' N. lat., and 69° 34'

E. long. Mandavee is the most populous place in the principality, and contains 50,000 inhabitants, who are principally Bhattias, Banyans, and Brahmins: there are but few Mohammedans. The port is an open roadstead with a creek; there are 250 vessels belonging to the place, by means of which a very considerable trade is carried on with Zanguebar and the whole east coast of Africa, with the Red Sea and Arabia, with the Persian Gulf, Mekran, and Sinde, and with India as far as Ceylon. The vessels employed in this traffic vary from 25 to 200 tons burthen; they carry a large lateen sail, and have two masts, but are never decked; they are navigated by native pilots, who have acquired the use of the quadrant, and steer by charts. The natives assert that the foreign trade of Mandavee has existed for a very long period, but it appears that the nautical skill of their mariners received great improvement from the instructions of a native Rajpoot named Ram-Sing, who was carried to Holland about a century ago, and after a residence in Europe of some years' duration, returned home 'with a knowledge of astronomy, navigation, ship-building, and other arts, which have been ever since preserved.' The most valuable branch of the trade of Mandavee is that carried on with the eastern coast of Africa, a distance of 3000 miles, whence the merchants of Cutch procure ivory, rhinoceros hides, and other valuable articles. The principal article of export is cotton. Rohur, also a seaport, is situated in the Gulf of Cutch opposite to Wumania on the Gujerat peninsula, and is in $23^{\circ} 2' N.$ lat., and $70^{\circ} 21' E.$ long., about twelve miles from Anjar: the depth of water in this part of the gulf does not admit the passage of any but small vessels. The chief trade of Rohur is carried on with Gujerat. Tahrah, a populous place, inhabited principally by Hindus, is a fortified town about thirty miles south-east from Luckput Bunder, on the road between that place and Mandavee.

The population of Cutch is estimated to amount to 400,000 souls, about one-half of whom are Mohammedans, and the greater part of the remaining half Hindus. The Jharejah tribe of Rajpoots, who were estimated in 1818 to amount to 12,000, are believers in the Koran, and at the same time adhere to many Hindu observances. This tribe, the chief of which is the Rao or sovereign prince of Cutch, is remarkable for the almost universal practice of female infanticide, a practice which the English government has vainly endeavoured to suppress. Captain Macmurdo, the political resident at Bhooj, expressed his opinion that the total number of females belonging by birth to the Jharejah tribe who were alive in 1818 did not exceed thirty. The morals of the tribe are in other respects said to be very degraded; they are ignorant, indolent, and almost universally addicted to the immoderate use of intoxicating liquors: their wives are all necessarily procured from among other tribes.

Engagements of amity were entered into between the British and the government of Cutch in 1809, ostensibly with a view to the suppression of piracy, but really for the exclusion of foreign Europeans from the country, a precautionary measure adopted in anticipation of a threatened invasion of India by the French. In 1815, in consequence of depredations committed by the subjects of Cutch on the territory of the Guicowar, our ally, an English force was sent into Cutch, the Rao was deposed, and a new chief placed upon the throne, who engaged to receive a subsidiary force; but the Rao whom the English installed having thrown the country into disorder by misgovernment, he was in turn deposed likewise in October, 1819, and his infant son, Mirza Rao Sree Dessuljee, set up in his stead, under a council of regency, of which the British resident was a member: this in effect placed the government of the country in the hands of the English. In 1822 a further treaty was made, restoring Anjar, which place had been ceded to the English in 1816. In return for this the government of Cutch agreed to pay 88,000 rupees per annum, in addition to an annual subsidy of two lacs of rupees previously payable. It was calculated that these sums, which together amounted to 28,800*l.*, would have absorbed about one-fourth part of the revenues of the state, but it was found in practice that they greatly exceeded one-half the net revenue, and repeated remissions of a considerable portion have been found necessary. In the political letter addressed by the Court of Directors to the Bombay government on 26th May, 1830, some of the evils are pointed out, which appear to be almost unavoidable under the system of interference adopted by the Anglo-Indian governments.

'You have been led,' say the Directors, 'into a much more minute interference in the internal administration of Cutch than entered into your contemplation when you formed the present arrangement for the government of that country. This extension of your direct authority has taken place, as is usual in such cases, by insensible degrees, evils having been found to be produced by partial interference which it required a greater interference to remedy.'

(*Reports of Committees of House of Commons on the Affairs of India in 1830 and 1832.*)

CUTICLE, the external skin of a plant. It is composed of one or more layers of empty flattened cells, which adhere firmly to each other, and serve as a protection to the succulent tender tissue placed beneath them. The thickness of the sides of the cells renders them well adapted to repel mechanical violence, and the air cavities which it contains give the cuticle great efficiency as a slow conductor of caloric, enabling it on the one hand to prevent the escape too rapidly of the internal heat of a plant, and on the other to guard the tissue against scorching by the too powerful action of the sun. Accordingly we find the cuticle thickest and most completely organized where it is most exposed to the action of the air, while in submerged plants, which never are exposed to the atmosphere at all, it is absent. When plants inhabit damp shady places, it is thinner; when they grow on hot dry rocks, it is thicker than usual; and it is in all cases found to be affected in a similar manner. Once removed it is never renewed.

Sometimes it has openings through it into air-chambers placed below it, and such openings are guarded by a pair of oblong parallel cells, which, by their expansion and contraction, close or widen the orifice. These organs are called stomates, and are supposed to be more particularly intended to assist in the respiration of plants.

CUTTACK, a district in the province of Orissa, bounded on the east by the Bay of Bengal, on the north-east by the province of Bengal, on the west by various Maharatta states; and on the south-west by the Northern Circars. Its length from north-east to south-west is 180 miles, and its average breadth 110 miles. On the coast, and for twenty miles inland, the country is low and covered with wood, and being subject to inundation at spring-tides is very marshy. Beyond twenty miles from the sea the country rises considerably, and the soil is dry and fertile. At a further distance inland of twenty miles it swells into hills, and is well wooded; some of the trees are valuable for cabinet work, and others are used in dyeing. The forests are much infested by wild beasts. The region thus lying beyond the marshy delta is called the Mogulbundy. Beyond this is a third region, which is hilly, and extends westward as far as Gundwana. This region is parcelled among sixteen hereditary Zamindars, who are under the protection of the English, and are considered as tributary rajahs, paying at the rate of about one-tenth of the net produce of their estates. The country is subdivided under these Zamindars into a great number of estates, which are also held by hereditary succession. A great variety of minerals are found in this hilly country: iron is met with in many parts; and inferior garnets in great quantities.

Cuttack is watered by numerous streams, which, during the rainy season, become large rivers. The principal of these are the Mahanuddy and its numerous branches, the Bhaminee, the Byturnee, and the Subunreeka. The Bhaminee rises in the mountains of Gundwana, and flowing first to the south and then to the east, traverses the district of Cuttack; uniting with the Beroopah, a branch of the Mahanuddy, it joins the sea near Point Palmyras. The Byturnee rises among the mountains of Chuta Nagpore in Bahar, and flows south through Gangpore in Gundwana: on entering Cuttack it turns to the south-east, and afterwards to the east, and falls into the Bay of Bengal in $20^{\circ} 48' N.$ lat. The Subunreeka likewise rises in Chuta Nagpore, and flows in a south-easterly direction, with a very winding course, for 250 miles, and joins the Bay of Bengal, forming the southern boundary of the province of Bengal. These rivers abound with fish.

The rainy season does not begin so early as in Bengal, but continues from September to November with so much violence as to cause the different rivers to overflow their banks. In November the weather again becomes fine. From April to June the heat is very oppressive, and would be hardly supportable but for occasional thunder storms, accompanied by rain. At other times the climate is more

temperate, but the thermometer seldom, if ever, sinks below 60°.

The manufacture of salt is carried on along nearly the whole of the coast; the produce is very white and pure, and yields a revenue of about eighteen lacs of rupees (180,000*l.*) per annum. The Mogulbundy produces rice and other grains, pulse, spices, dyeing stuffs, and sugar. Maize and wheat are the chief products in the hilly country farther inland. During the periodical rains, when the rivers are full, a good deal of teak and other timber is floated down to the coast. The forests in which this timber is cut are very unhealthy, and for that reason can be visited only at certain seasons of the year.

The principal towns of the district are Cuttack, Balasore, and Juggernaut. [CUTTACK, BALASORE, JUGGERNAUTH.] The other towns, or rather large villages, deserving of mention, are Buddruck, Soroli, and Piply. Buddruck is thirty-eight miles S. S. W. from Balasore, in 21° 7' N. lat. and 86° 26' E. long. It is this village and its neighbourhood that furnish most of the people who are known in Calcutta as Balasore bearers. Soroli is about twenty-three miles south-west from Balasore; it contains two fine tanks and the ruins of a mud fort. Piply is twenty-seven miles south from the town of Cuttack, in 20° 5' N. lat. and 85° 58' E. long. The district contains a great number of small villages. The whole population, including the inhabitants of the three principal towns, was estimated in 1822 at 1,296,365. The revenue consists of the profits of the salt monopoly already mentioned; the land assessment, amounting to fourteen lacs of rupees (140,000*l.*), nearly all of which sum is collected in the Mogulbundy; customs-duties, pilgrim tax, and other minor sources, about one lac in addition. Making allowance for the expenses of collection, the annual revenue derived from the district is about thirty lacs of rupees, or 300,000*l.* A great part of the circulating medium is composed of cowries, supplies of which are obtained every year from the Maldivé Islands in return for grain. A considerable amount of bullion is carried into Cuttack by pilgrims, but this for the most part finds its way to Calcutta.

The district of Cuttack, including Balasore and other dependencies, was ceded to the East India Company, in full sovereignty, by the rajah of Berar, in January, 1804; the fort and town of Cuttack were taken by the English army in the month of October preceding. The salt monopoly was partially introduced soon after the acquisition of the territory, but was first legally recognized by the government in 1814. The measures at first pursued operated rather to restrict the supply than to subject the article to taxation, and much distress was thereby occasioned to the people without producing any adequate addition to the government revenues. This circumstance, combined with the too rapid introduction of a new revenue system, and the consequent sales of land for arrears of rent, whereby in the course of eleven years a transfer had been effected of more than one-half of the settled lands in the Mogulbundy from the original possessors, excited so much exasperation, that a very serious revolt was attempted in 1817, and this was not fully quelled until two years after, causing a considerable sacrifice of lives. After this insurrection was quelled, arrangements were made for supplying the district with salt by an extended system of local sales, at fixed prices, below those of the auction sales at Calcutta, and by this means a much larger quantity has been sold for consumption within the district, the revenue has been improved, and the people have been relieved from what was felt as a severe oppression.

(Rennell's *Memoir*; *Reports of Committee of Commons on the affairs of India*, 1832; *Revenue and Judicial Selections*, printed by the East India Company.)

CUTTACK, the capital of the district, is situated in 20° 27' N. lat., and 86° 5' E. long. The town is built on a tongue of land between two branches of the Mahanuddy river. During the rainy season Cuttack is completely insulated, and the town itself would be subject to periodical inundations but for large and solid embankments faced with cut stone, which effectually keep out the water. The necessity and at the same time the efficacy of these embankments were proved during the heavy rains of 1817, when the waters rose in one night eighteen feet. The river, during the rains, is a mile and a half broad, and from thirty to forty feet deep at this part, but during the dry season it is a narrow stream with a depth of only three feet.

The Sanscrit word Catak, from which the name of the town is derived, signifies a royal residence. While the province of Orissa preserved its independence, Cuttack was the residence of the Gajapati, or superior rajah, at whose court the military chiefs of Orissa performed feudal service. The Mogulbundy already described, formed the fisc or domain of the Gajapati, while the holdings of the military chiefs were situated round and along the frontier of the kingdom, and it was the duty of their possessors to defend the country from the irruptions of neighbouring powers in the same manner as the lords of the marches in Europe were in former days required to repel invaders.

The town contains a very well-built street with houses of stone two and three stories high, a large market-place, and several mosques; in one of these is exhibited a stone brought from Mecca, and bearing an impression of the foot of Mohammed. In 1822 the town contained altogether 6500 houses and 40,000 inhabitants. The fortress of Barabuttee, which was built in the fourteenth century, stands about a mile north-west from the town. Cuttack is 251 miles from Calcutta, 482 miles from Nagpore, 651 from Hyderabad, 779 from Madras, and 902 miles from Delhi, all travelling distances. (Rennell's *Memoirs*; Col. Briggs *on the Land Tax in India*.)

CUTTING, in gardening, is a portion of a plant from which a new individual is propagated when placed in the earth. Every body knows that a stick of willow stuck into the ground will put forth roots, and become a new plant; such an instance is a rude exemplification of the manner of multiplying plants by cuttings. In the empirical rules to be observed in this operation, the reader had better consult some book on gardening; we shall confine our observations to the theory of the operation.

Every bud which a plant contains is a distinct seat of life, capable, under fitting circumstances, of growing, flowering, fruiting, seeding, independently of all other buds, and able, if separated from the mother plant, to form a new individual. The buds of a vine, and of a potato, are actually so employed under the name of *eyes*; a cutting is merely a small collection of eyes adhering to a mass of woody matter.

A cutting, when prepared for planting, is cut off close to a bud at the bottom, and down to another at the upper end; it is then placed in earth quite up to its topmost bud, the remainder being buried. The object of this is threefold: firstly, to expose only one bud to the stimulus of light, so that when the cutting begins to grow the leaves may not, from their number, require more food than the woody system can supply; secondly, to keep back the other eyes by the pressure of the earth upon them; and thirdly, to expose as great a surface of the cutting as possible to the influence of the moist earth and darkness, by means of which the production of roots will be facilitated.

In delicate operations, where cuttings are difficult to strike, several additional practices are had recourse to. The cuttings are covered with a bell glass, in order to keep the air that surrounds them saturated with moisture, so that when the buds begin to grow they may not exhaust the cutting of its vital fluid by their excessive evaporation. They are shaded with the same object in view; sun-light increases evaporation, and stimulates a growing part into action: the desire of the gardener is to guard against this till his cuttings have formed abundant roots to feed by. When cuttings are very difficult to strike, their lower end is often made to rest upon the bottom of the garden-pot in which they are to grow; this removes their wounded end from too much moisture, and prevents their being gorged with crude sap before they are able to digest it, an evil quite as great as that of being exhausted by too rapid a digestion. The same or a similar purpose is answered by putting the cuttings in the first instance into pure silex (silver sand), from which they are removed as soon as roots are emitted; such sand permits only a slow transmission of water through it, and is in fact incapable of supersaturation if proper means are taken to drain it; and hence it renders it impossible that water should be conveyed too quickly into the open vessels of the cutting.

In many cases a single leaf, or a portion of one, is left attached to the upper eye of the cutting; this is for the sake of keeping up a slow circulation in the system, and of drawing into the vessels of the wood a gentle current of moisture, so that the cutting may never be too much exhausted.

When cuttings will not strike because they are too young, the cause is to be sought in the young tissue being too absorbent, and taking up moisture faster than it can digest it, the result of which is a repletion of the vessels, disease, and death. On the other hand, cuttings the wood of which is too old will not strike from an opposite cause; their vessels are so small and rigid, that when the young leaves are ready to expand, and the new roots to develop, the supply of food moves too sluggishly through the cutting from point to point, and hence the new parts wither if formed, or will not form at all. The exact age at which a cutting roots most readily is a matter of experiment, and not capable of being reduced to any theoretical rule.

It is highly probable that if these points are well considered, all plants, of whatever nature, provided they have well-formed buds, are capable of striking from cuttings; and it is notorious, that while some gardeners can only succeed with the commonest things, others, by the success that attends their operations, possess what would seem a magical power over plants, if we did not know that natural magic consists in nothing more than the right application of right knowledge at the right time.

CUTTLE-FISH. [CEPHALOPODA, vol. vi., p. 425; SEPIADÆ.]

CUVIER, GEORGES, was born August 23, 1769, at Montbéliard, now in the department of Doubs, but which at that time was a county belonging to the dukes of Würtemberg. His father, a half-pay officer of a Swiss regiment in the French service, had married late in life a young and accomplished woman, who took especial care of Cuvier's early education. He was sent to study first at Tübingen, and he afterwards entered the Academia Carolina, then newly established at Stuttgart by Prince Charles of Würtemberg for the purpose of training up young men for public and diplomatic offices. Cuvier, however, bestowed most of his time on natural history; he collected specimens, and drew and coloured insects, birds, and plants during his hours of recreation. The limited circumstances of his family obliged him to remove from Stuttgart before he obtained any public employment; and at twenty-one years of age he accepted the situation of tutor to the only son of Count d'Hericy in Normandy. The family residence being near the sea, the study of marine animals became a part of Cuvier's occupation. He compared the living species with the fossil remains found in the neighbourhood; and the dissection of a species of cuttle-fish led him to study the anatomy of the mollusca, and to reduce to order this hitherto neglected branch of zoology. While he was thus employed, a society was formed at Valmont, in his neighbourhood, for the encouragement of agriculture. L'Abbé Teissier, a venerable and learned old man, the author of the articles on agriculture in the 'Encyclopédie Méthodique,' had taken refuge at Valmont from the revolution, disguising his obnoxious character of Abbé under the garb and profession of a surgeon. At a meeting of the new society he expressed his opinions on his favourite subject in a manner which forcibly reminded young Cuvier of the articles which he had read in the *Encyclopédie*. At the end of the sitting Cuvier addressed the stranger by the name of l'Abbé Teissier: the abbé was alarmed, but Cuvier soon removed his apprehensions, and an intimacy was formed between them. When the reign of terror had ceased, Teissier wrote to Jussieu and other friends at Paris in terms of high commendation of his new acquaintance. The result was, that Cuvier was requested to forward some of his papers to the Society of Natural History, and shortly after, in 1795, being then 26 years of age, he went to Paris, and in the same year was appointed assistant to Mertrud in the superintendence of the Jardin des Plantes, which locality became from that time his home, and the scene of his labours and of his fame. Here he began the creation of that now splendid collection of comparative anatomy, and in December of the same year he opened his first course on that branch of science. In 1796 the National Institute was formed, and Cuvier was one of its first members. In 1798 he published his 'Tableau élémentaire de l'Histoire Naturelle des Animaux,' and afterwards his 'Mémoire sur les Ossements Fossiles des Quadrupèdes' and 'Mémoire sur les Ossements Fossiles qui se trouvent dans les Gypses de Montmartre.' He continued to illustrate the subject of fossil remains by subsequent memoirs. In the year 1800 he was named professor of natural philosophy at the Collège de France, continuing at the

same time his lectures on comparative anatomy at the Jardin des Plantes. In that year were published the first two volumes of his 'Leçons d'Anatomie Comparée,' which met with the greatest success. The three following volumes appeared in 1805. In 1802 the first consul Bonaparte appointed Cuvier one of the six inspectors-general for establishing lycea, or public schools, which were supported by government in thirty towns of France, and which are now called Royal Colleges. Cuvier established those of Marseilles, Nice, and Bordeaux. He was about the same time appointed perpetual secretary to the Institute for the Department of Natural Sciences, with a salary of 6000 francs. In 1803 he married the widow of M. Duvancel, a former fermier général: four children whom he had by this marriage all died before him. In 1808 he was commissioned by Napoleon to write a report on the progress of the natural sciences from the year 1789. The luminous and interesting treatise which he produced on this occasion was formally presented to Napoleon in the council of state. Cuvier declares the true object of science to be, 'to lead the mind of man towards its noble destination—a knowledge of truth—to spread sound and wholesome ideas among the lowest classes of the people, to draw human beings from the empire of prejudices and passions, to make reason the arbitrator and supreme guide of public opinion.' His next appointment was that of counsellor for life of the new Imperial University, in which capacity he had frequent personal intercourse with Napoleon. In 1809-10 he was charged with the organization of the new academies, the name designed to be given to the old universities of the Italian states which were annexed to the empire. He organized those of Piedmont, Genoa, and Tuscany. His reports of those missions exhibit the mild and enlightened spirit which he brought to the task. Speaking of the universities of Tuscany, he deprecates a too hasty and rash interference with institutions which had been founded and sustained by so many great men, and in which he found much to praise and to retain. In 1811 he was sent on a similar mission to Holland and the Hanseatic towns: his report especially concerning Holland is very interesting, as the subject of public instruction in that country is not generally known. He paid particular attention not only to the higher branches of education, but also to popular or elementary instruction; his principle was, that instruction would lead to civilization, and civilization to morality, and therefore that primary or elementary instruction should give to the people every means of fully exercising their industry without disgusting them with their condition; that secondary instruction, such as in the lycea, should expand the mind, without rendering it false or presumptuous; and that special or scientific instruction should give to France magistrates, physicians, advocates, generals, clergymen, professors, and other men of learning. His words were: 'Give schools before political rights; make citizens comprehend the duties that the state of society imposes on them; teach them what are political rights before you offer them for their enjoyment: then all amelioration will be made without causing a shock; then each new idea, thrown upon good ground, will have time to germinate, to grow, and to ripen, without convulsing the social body. Imitate nature, which, in the development of beings, acts by gradation, and gives time to every member to grow to perfection. The infant remains nine months in its mother's womb; man's physical perfection only takes place between twenty and thirty, and his moral completion from thirty to forty. Institutions must have ages to produce all their fruits; witness christianity, the effects of which are not yet accomplished, notwithstanding eighteen centuries of existence.' (Laurillard, *Eloge de M. le Baron Cuvier*.)

In 1813 Cuvier was sent to Rome, then annexed to the French empire, to organize the universities there. Although his being a Protestant rendered this mission the more delicate, yet his enlightened tolerance and benignity of manner gained him the general esteem and approbation in the capital of the Catholic world. Soon after Napoleon appointed him maître des requêtes to the council of state; and in 1814, just before his abdication, he named him councillor of state, an appointment which was confirmed by Louis XVIII., who soon after appointed him chancellor of the university, an office which he held till his death. In both these capacities he found himself at times in a very trying position, arising from the intolerance and bigotry of certain individuals of influence about court.

In 1817 he published a second edition of the 'Recherches sur les Ossements Fossiles,' in 5 vols., 8vo., and also his 'Règne Animal,' in 4 vols., in which the whole subject-matter of zoology is arranged according to the principle of organization. It begins with man, of whom he recognizes only one genus and one species, diversified by varieties called races. In 1818 he made a journey to England, where he was received with appropriate honour. In the same year he was elected a member of the French Academy. In 1819 he was appointed president of the committee of the interior in the council of state, an office which, fortunately for him, was beyond the sphere of political intrigues, and only required order, impartiality, and an exact knowledge of the laws and principles of the administration. In the same year Louis XVIII., as a personal mark of his regard, created him a baron. He was appointed also temporary grand master of the University, an office however which he willingly resigned for that of grand master of the Faculties of Protestant Theology in 1822. He himself stipulated that he should receive no salary for this latter office. He was made at the same time one of the vice-presidents of the Bible Society. Through his care fifty new Protestant cures were created in France. He also established new professorships of history, living languages, and natural history, in the minor schools of the kingdom. In 1825 he republished, separately, the preliminary discourse to the 'Recherches sur les Ossements Fossiles,' which is generally known by the title of 'Discours sur les Révolutions de la Surface du Globe,' and has been translated into most European languages under the title of 'Theory of the Earth.' This work is not a system of mere speculative theory, but a series of deductions from actual facts, authenticated by his own researches into the fossil remains, classed according to the strata in which they were found. Cuvier draws the following conclusions: 1st. That in the strata called primitive there are no remains of life or organized existence. 2nd. That all organized existences were not created at the same time, but at different times, probably very remote from each other; vegetables before animals, the mollusca and fishes before reptiles, and the latter before the mammalia. The transition limestone exhibits the remains of the lowest forms of existence; the chalk and clay conceal the remains of fishes, reptiles, and quadrupeds, the beings of a former order of things which have now disappeared. 3rd. That among fossil remains no vestige appears of man or his works, no bones of monkeys are found, no specimen of the whole tribe of quadrumanous animals. 4th. That the fossil remains in the more recent strata are those which approach nearest to the present type of the corresponding living species. 5th. That the stratified layers which form the crust of the globe are divisible into two classes, one formed by fresh water and the other formed in the waters of the sea; a fact which leads to the conclusion that several parts of the globe have been alternately covered by the sea and by fresh water. From these and other facts, Cuvier concludes that the actual order of things on the surface of our globe did not commence at a very remote time: he agrees with Deluc and Dolomieu, that the surface of the earth was subject to a great and sudden revolution not longer than five or six thousand years ago, and that this catastrophe caused the disappearance of countries formerly the abode of man and of species of animals now unknown to us. But he also believes that the countries now inhabited had been at some former period, long before the creation of man, inhabited by land animals, which were destroyed by some previous convulsion, and that this globe has undergone two or three such visitations, which destroyed as many orders of animals, of which we find the remains in the various strata. At the close of his work on fossil remains he thus modestly expresses himself: 'I have no doubt, that in a few years, the work which I now terminate, and to which I have devoted so much labour, will be but a trifling sketch, a first glance thrown over the immense creations of antient times.'

In 1826 Charles X. bestowed on Cuvier the decoration of grand officer of the legion of honour; and the king of Würtemberg, his former sovereign, made him commander of his order of the crown. In 1827 Cuvier, as a member of the cabinet of the interior, was intrusted with the superintendence of all affairs concerning the different religions professed in France, except the Catholic. In the same year he had the misfortune to lose his only remaining child, a daughter, amiable and accomplished, and on the eve of her

marriage; a loss from which he never entirely recovered, although a sense of his public duties made him stifle his grief. In 1828 appeared the first volume of his 'Histoire Naturelle des Poissons,' a splendid work, of which he lived to see eight volumes published, and which has been since continued, and is to be completed in twenty volumes. It contains more than 5000 species of fishes, described from real specimens and classed, with observations on their anatomy, and critical researches on their nomenclature, antient as well as modern.

In 1830 Cuvier opened a course in the Collège de France on the history and progress of science, and especially of the natural sciences, in all ages. In the same year he paid a second visit to England, and it was during his absence from Paris that the revolution of July took place. On his return he was graciously received by the new king Louis Philippe, who in 1832 made him a peer of France. On the 8th of May of that year, he opened the third and concluding part of his course of lectures on the history of science, by summing up all that he had previously said; he then pointed out what remained for him to say respecting this earth and its changes, and announced his intention of unfolding his own manner of viewing the present state of creation. This discourse, delivered in a calm solemn manner, produced a deep impression on his hearers, which was increased when he added the concluding words: 'These will be the objects of our future investigations, if time, health, and strength, shall be given to me to continue and finish them with you.' That was his last lecture. The following day he felt ill, and soon after paralysis manifested itself. He saw the approach of death with resignation, and on the 13th he expired, at the age of sixty-three, universally regretted. He was buried in the cemetery of Père la Chaise; his funeral was attended by deputations from the Council of State, the several academies, by members of the two Chambers, &c.

The career of this great and good man, passed quietly but most usefully in the pursuits of science, and in instructing and benefiting mankind, during forty years the most eventful in the history of France and of Europe, forms a striking contrast with that of the conquerors and politicians who agitated the world during the same period. His works, of which we have mentioned a few of the most important, are very numerous, and even a mere catalogue of them would exceed our limits. The reader will find a full list of them in chronological order in the very interesting *Memoir of Baron Cuvier*, by Mrs. R. Lee, to which, as well as to a well written article on the *Life and Labours of Cuvier* in No. XXVIII. of the *Foreign Quarterly Review*, December, 1834, we are indebted for most of the materials of this notice. Numerous eulogies of Cuvier have also appeared in France, by MM. Duvernoy, Pariset, Laurillard, &c.

Cuvier himself wrote numerous eulogies, among others, of Bruguières, Daubenton, Lemonnier, Priestley, Adanson, Saussure, Bonnet, Fourcroy, Pallas, Rumford, Werner, Sir Joseph Banks, Delambre, Berthollet, Lapeyrou, Fabbroni, Ramond, Sir Humphry Davy, &c. These eulogies, which are really interesting biographies, have been published in 3 vols., 8vo. He also contributed to the 'Dictionnaire des Sciences Medicales,' the 'Biographie Universelle,' and to the 'Dictionnaire des Sciences Naturelles.' The article 'Nature,' in the last, is deserving of especial attention. There is a little work of Cuvier, a small 12mo., which although out of the sphere of his general studies, deserves mention. It consists of a discourse on the distribution of the annual prize established by the philanthropist M. de Montyon under the name of 'prix de vertu,' to be given to those who have excelled by their active virtues in doing good to their fellow-creatures. Louise Scheppler, the villager of the Vosges, and disciple of the venerable Oberlin, was one of those who received the prize.

CUXHAVEN, a large and important harbour on the left bank of the Elbe, at its entrance into the German Ocean. It is situated in 53° 53' N. lat. and 8° 44' E. long. in the bailiwick of Ritzebüttel, which lies along the northern shores of the Hanoverian duchy of Bremen, and belongs to the free city of Hamburg. It affords a secure shelter against this dangerous sea in the winter months, or to ships waiting for fair winds. It contains about 800 inhabitants, chiefly pilots and fishermen; has a lighthouse, excellent bathing establishments, and arrangements for the performance of quarantine. There is also a regular communication with England by the packets, which formerly took their departure

from Cuxhaven. The chief magistracy is always vested in a senator of Hamburg.

CUZCO, a town in South America, in the Republic of Peru, 260 miles from the Pacific, $13^{\circ} 42'$ S. lat., and $71^{\circ} 4'$ W. long. Before the arrival of the Spaniards it was the capital of the extensive empire of the Incas, and is said to have been built by the founder of the empire, Manco Capac, in the tenth or eleventh century of our æra. In the year 1534, when it was taken by Francis Pizarro, the Spaniards were astonished at the magnificent buildings which it contained, especially the Temple of the Sun. Of this temple there remain at present only some walls of singular construction, upon which stands the magnificent convent of Santo Domingo.

The town is built at the foot of some hills in the middle of a wide valley, which has an undulating surface. This valley extends eastwards to a mountain stream, the Quillabamba, and in the lower part is well cultivated, the fields having the advantage of irrigation. The houses of Cuzco are built of stone, covered with red tiles. Many of them still retain their original walls. The great size of the stones used in their construction, the variety of their shapes, and the excellent workmanship which they display, give to the city an interesting air of antiquity. The cathedral, the convents of S. Augustin and of La Merced, are very large buildings, inferior in architecture to few in the old world.

Upon a lofty hill, a little north of the city, are the ruins of a great fortress, many parts of the wall of which are even now in perfect preservation. They consist of stones of extraordinary size, and of polygonal shapes, placed one upon another without cement, but fitted with such nicety as not to admit the insertion of a knife between them. This stupendous work was erected by the Incas for the protection of their capital.

The population exceeds 40,000, of whom a great part are Indians, who are distinguished by their industry; they manufacture cotton and woollen goods, and tan leather. Their embroideries and carved furniture are much valued. The town formerly contained several institutions for education, as a university, two colleges, &c.; but we do not know what changes have taken place in this respect since the expulsion of the Spaniards.

The great high road of the Incas extended from this town northward as far as Quito, and southwards probably to the southern extremity of the valley of the Desaguadero to the neighbourhood of Oruro, or from the equator to 20° south lat. (Ulloa; *Memoirs of General Miller*.)

CYANIC ACID, a compound of cyanogen and oxygen. When a mixture of ferrocyanide of potassium and binoxide of manganese is heated to redness, and the residue is boiled in alcohol of specific gravity 0.86, tabular crystals are formed as the solution cools, which are cyanate of potash; this acid forms insoluble salts with solutions of lead, silver, &c., and when these are diffused through water and sulphuretted hydrogen is made to act upon them, metallic sulphurets are precipitated, and cyanic acid remains in solution; this is a sour fluid, the smell of which resembles that of vinegar; it decomposes with great facility. It is composed of

Two equiv. of Carbon	12	} = One equiv. Cyanogen	26
One „ Azote	14		
		One „ Oxygen	8
		Equivalent	34

There is another acid, constituted of similar proportions of cyanogen and oxygen, which is isomeric with this acid; but which, on account of the explosive nature of some of its salts, is called *fulminic acid*. [FULMINIC ACID.]

CYANOGEN, or bicarburet of azote, is a gaseous compound sometimes termed *Prussine* or *Prussine gas*. This gas was discovered by Gay Lussac in 1815; it is prepared by heating bicyanide of mercury in a retort by means of a spirit lamp; the cyanogen comes over in the gaseous state, and metallic mercury is distilled. This gas is colourless, and has a peculiar and pungent odour; under a pressure of 3.6 atmospheres, and at a temperature of 45° , it is reduced to the state of a limpid fluid, but which resumes the gaseous state when the pressure is removed. It is inflammable and burns with a purple flame; but a taper immersed in it is extinguished. It is not readily decomposed by heat. At the temperature of 60° water absorbs 4.5 times its bulk, and alcohol 23 times. The acid property of reddening litmus paper is exhibited by the aqueous solu-

tion; but this is probably dependent upon the formation of acids by the mutual decomposition of the cyanogen and water. The name of cyanogen is derived from *κίανος*, blue, and *γενος*, a termination common to many other chemical terms, as oxygen, hydrogen, &c. It is an essential ingredient of Prussian blue.

This gas is composed of 100 cubic inches of azotic gas, weighing 30.1 grains, and holding $25.1 = 55.9$ gr. of carbon in solution; its specific gravity is therefore to that of atmospheric air as 1.803 to 1. It is constituted of

Two equivalents of carbon	12
One „ azote	14

Equivalent 26

When one volume of this gas is mixed and detonated with two of oxygen over mercury, there are produced two volumes of carbonic acid gas and one volume of azotic gas. Cyanogen combines with several metals to form single and double cyanides or cyanurets. One of the most useful and remarkable of the simple cyanides is the well-known pigment Prussian-blue, which is composed of 9 equivalents of cyanogen and 7 equivalents of iron. A double and well-known cyanide is the ferrocyanide of potassium; it is a crystalline salt of a fine yellow colour, prepared by heating animal matter and potash in an iron vessel; the residue is a coaly matter which is partially soluble in water, and by evaporation gives the crystals in question. These are composed of one equivalent of cyanide of iron 54, two of cyanide of potassium 132, and three of water $27 = 213$. This salt, when added to a solution of sulphate of iron with certain precautions, produces percyanide of iron or Prussian blue.

Cyanogen combines with various elementary bodies to form peculiar compounds; thus with hydrogen it forms prussic or hydrocyanic acid; it unites also with chlorine and sulphur to form chlorocyanic and sulphocyanic acids.

CYCADA'CEÆ, one of the natural orders of Gymnospermous plants. It is essentially characterized by its trunk growing in a cylindrical unbranched manner in consequence of the development of one terminal bud only, and by its diœcious flowers, of which the males at least grow in cones, composed of peltate scales. In one genus, *Zamia*,

[*Cycas circinalis*.]

1, a male cone; 2, a female spike; 3, a section of a ripe fruit.

the female flowers also are disposed in the same manner; in the other, *Cycas*, they are placed upon the toothings of abortive leaves, occupying the centre of the terminal bud. The leaves of these plants are pinnated, and have a certain resemblance to those both of ferns and palms; their wood is arranged both in concentric circles, which in *Cycas* are numerous, and in a confused manner among the central pith; so that a Cycadaceous stem partakes in structure of the peculiarities of both Exogens and Endogens. In the manner in which their leaves unroll, and in their terminal single bud, Cycadaceæ resemble Ferns, with which they may moreover be compared on account of their fruit proceeding from leaves; with Coniferæ they accord in the cone-like arrangement of their parts of fructification and their naked ovules; and with Palms in the secretion of a large quantity of fœcula in their stem, in their mode of growth, and in the arrangement of a part of their woody system. Cycadaceæ therefore, belonging as they do to Gymnosperms, possess nearly equal affinity with Palms or Endogens, and Tree-ferns, or Acrogens.

A few plants inhabiting India, New Holland, the Cape of Good Hope, and tropical America, constitute the whole of this order, all the species of which contain a large quantity of fœcula in their trunk. *Cycas circinalis* yields a coarse sort of sago in the East Indies, and arrow-root of the finest quality is manufactured from *Zamia furfuracea* in the West Indies.

CYCLADES. [ARCHIPELAGO, GRECIAN.]

CYCLANTHACEÆ, a highly curious but little known natural order of plants, allied to Pandanaceæ, from which their habit and fructification distinctly divide them. They have plaited, slit, stalked leaves, and a spadiceous inflorescence like Araceæ; the flowers are arranged in spiral bands upon the spadix, one band being alternately male and the other female. The whole order consists of a very small number of tropical American plants. (See Lindley's *Natural System of Botany*, p. 362.)

[*Cyclanthus bipartitus*.]

1, a panel of stamens from a male ring; 2, a section of a spadix; 3, the upper portion of an entire spadix.

CYCLAS. [VENERIDÆ.]

CYCLE. This term, which means nothing but circle

(κύκλος), has an arbitrary use in chronology. Certain of the cycles, or recurring methods of denoting time, which are in common use, are called cycles, to the exclusion of the rest. The principal of these, if not the only ones, are the Metonic cycle [METON, CALIPPUS], the SOLAR cycle, and the cycle of INDICATION. But the natural cycles, such as the revolutions of the sun and moon, are not called cycles; nor even some of the artificial ones, such as the Julian period. It would be useless to retain this artificial and confused distinction. Under the distinctive words METON, INDICATION, &c., the reader will find the origin of each method of reckoning; while in the article PERIOD OF REVOLUTION he will see a table of the lengths and commencements of all the cycles, natural and artificial, whether called cycle, period, year, day, or month.

CYCLICA, a section of coleopterous insects. According to Latreille, this group forms a subsection of the section Tetramera; the groups Tetramera, as well as Pentamera, however, we imagine are somewhat artificial. See COLEOPTERA.

The section Cyclica contains the Linnæan genera *Hispa*, *Cassida*, and *Chrysomela*, the species of which may be distinguished by the following characters:—Tarsi four-jointed, furnished beneath with a velvet-like substance; the penultimate joint bilobed; antennæ of moderate length, generally filiform, or increasing in thickness towards the apex; body usually of a rounded or oval form, the thorax being, at the base of the same width as the elytra.

These insects are usually of brilliant metallic colouring: various shades of green appear to predominate. Their larvæ have a soft body, and are furnished with six legs, attached two to each of the three first segments, or those next the head. They feed upon the leaves of plants.

To this group belong the following families:—*Cassidiadæ*, *Chrysomelidæ*, and *Galerucidæ**. The principal genera belonging to the family Cassidiadæ are, *Alurnus*, *Hispa*, *Chalepus*, and *Cassida*. To these genera we shall at present confine our remarks, commencing with the genus *Cassida*, the technical characters of which are:—Body oval or rounded, depressed; thorax generally somewhat semicircular, with the anterior portion produced so as to conceal the head; mandibles with three notches on the inner edge; external lobe of the maxilla as long as the inner one.

The Cassidæ are usually of a somewhat flattened form, and are remarkable for their having the external margins of the elytra projecting beyond the body; the outer margins of the thorax are also produced, and conceal the head. Those parts which extend beyond the animal itself are generally semitransparent and flattened, whilst the parts which immediately cover the insect are more or less convex. When the insect is at rest, the legs, which are rather short and compressed, are retracted, and the external margins of the elytra and thorax are applied closely to the plant on which it lives. The larvæ of the Cassidæ are of a depressed form, and usually armed on the upper parts with numerous little spines; these are longest on the sides of the body and at the tail. The use of these little spines appears to be for the purpose of holding the excrement of the animal, which is always deposited upon its back, and probably serves as a means of defence, by concealing it from its enemies.

Cassida viridis, an insect not uncommon in this country, is about a quarter of an inch in length, and of a bright green colour above; the body beneath is black. This species lives both in the larva and imago states upon thistles.

Mr. Stephens, in his 'Catalogue of British Insects,' enumerates nineteen species of this genus.

The insects belonging to the other three genera of the Cassidiadæ have the body of a more elongated form than those just described, and the head is exposed, the margins of the thorax and elytra not being produced. They are all included in the genus *Hispa* of Linnæus.

CYCLOBRANCHIANS. (Cuv.) [CYCLOBRANCHIATA. CERVICOBRANCHIATA.]

CYCLOBRANCHIATA. M. De Blainville's third order of the second section of his subclass *Paracephalophora monoica*.

Family character.—Organs of respiration branchial, in form of foliated branches, placed together symmetrically near the vent, which is situated in the mesial line of the posterior part of the body. Skin naked, and more or less tuberculous. (De Blainville.)

* The characters of these families are given under their proper heads

Genera Doris.*

Body oval, more or less depressed; the borders of the mantle going beyond the foot and head on all sides. Four *tentacula*, two of which are superior and contractile within a cavity, and two inferior under the border of the mantle. Mouth at the extremity of a small fleshy tube, without teeth, but with a lingual mass beset with denticles of some size. Branchiæ ramified, or in form of projecting foliated branches, disposed in a circle more or less complete in front of the vent. Organs of generation terminating on the anterior part of the right side in a common tubercle.

a.

Species which have the anterior border of the mantle divided into many strap-like portions symmetrically disposed. (Genus *Polycera*, Cuv.) Example, *Doris cornuta*.

[*Doris cornuta*.]

a, seen from above; b, seen from below; c, side view

β.

Species the anterior border of whose mantle is undivided.

*

Body prismatic.

Example, *Doris lacera*.

[*Doris lacera*.]

**

Body very convex (bombé) above.

Example, *Doris verrucosa*.

Body extremely depressed.

Example, *Doris Solea*.

[*Doris Solea*.]

Habits, &c.—There are many species spread abroad in almost all seas, where they live upon rocks. The student should refer to Cuvier's monograph in the *Annales du Museum*, vol. iv.; and to De Blainville's in the *Dictionnaire des Sciences Naturelles*.

Onchidoris.

Body oval, tumefied (bombé) above. Foot oval, thick,

* The term *Doris* was originally applied by Linnæus to an animal of this genus. Müller and Gmelin afterwards extended it to all the *Nudibranchiata* or Mollusks with naked branchiæ. Cuvier and De Blainville have restrained it: as above.

overpassed throughout its circumference by the borders of the mantle. Four *tentacula* as in *Doris*, besides the labial appendages. Organs of respiration formed by very small ramifications, disposed circularly, and contained in a cavity situated at the posterior and mesial part of the back. Vent mesial at the inferior and posterior part of the border of the mantle. Orifices of the organs of generation very distant, and united by an external furrow occupying the entire length of the right side. Example, *Onchidoris Leachii*.

[*Onchidoris Leachii*.]

a, side view; b, seen from below.

M. De Blainville established this genus for a mollusk in the British Museum, the locality of which was unknown.

Peronia.

Body suboval, tumefied above. Foot oval, thick, overpassed throughout its circumference by the borders of the mantle. Two inferior *tentacula* only, depressed, and but little contractile, and two labial appendages. Respiratory organ nearly retiform or pulmonary, in a cavity situated at the posterior region of the back, and opening externally by a rounded mesial orifice, pierced at the inferior and posterior part of the borders of the mantle. Vent mesial, situated in front of the pulmonary orifice. Orifices of the organs of generation very distant; that of the ovary entirely at the posterior extremity of the right side, continued by a furrow to the root of the labial appendage of that side: orifice of the exciting organ very large, nearly mesial at the anterior part of the root of the tentacle of the same side. Example, *Peronia Mauritiana*.

[*Peronia Mauritiana*.]

a, side view; b, seen from below.

M. De Blainville observes, that this genus contains the marine *Onchidia* of Cuvier, and that he knows of four or five species, all from the southern hemisphere.

N. B. The *Cyclobranches*, Cyclobranchians of Cuvier, form the eighth order of Gastropods of that zoologist, and contain the genera *Patella*, Linn., and *Chiton*, Linn. CER-VICOBRANCHIATA, vol. vi., p. 440 et seq.; CHITONS, vol. vii., p. 94 et seq.

CYCLOID (κυκλοειδής, like a circle), a name very incorrectly given to the curve which is traced out by any point of a circle rolling on a straight line. Thus while the wheel of a carriage revolves, each nail on the circumference describes a succession of cycloids. We might also here describe the various curves made by the points of circles which roll inside or outside of other circles, &c. &c. But as the cycloid stands apart from all the rest, both in simplicity and historical notoriety, we shall here confine ourselves to this one curve alone, and refer the rest to the head TROCHOIDAL CURVES.

If we suppose a circle to roll on a straight line, it is obvious that the centre will advance in every moment through a length equal to the portion of the circumference which is brought in contact with the line on which the circle rolls. That is,

Supposing C, the point now highest on the circle, to be the one whose path is to be traced, then, by the time the mere rotation would have brought this point to P, the whole system will have been carried forward through a length PQ equal to the arc CP. Hence follows a very simple mode of conceiving the form of a cycloid: at every point P imagine a line PQ parallel to AB and equal to the arc CP; the extremities of all these lines will be in the cycloid. The arc AC, through which the point on the circle rises from the line AB to its highest position, is similar and equal to the arc CB through which it descends. In the diagram we see small parts of the preceding and succeeding cycloids.

The principal properties of the cycloid are as follows:—

1. PQ is equal in length to the arc CP.
2. The tangent at Q is parallel to the chord CP.
3. The arc CQ is twice the chord CP, and the whole arc ACB is four times CE, the diameter of the generating circle.
4. Complete the rectangle CQR; the area CQR is equal to the circular area CPM, and the whole area ACB is three times that of the generating circle.
5. The curvature at Q is the same as that in a circle whose radius is twice EP, and the involute and evolute (see these terms) of a cycloid are both cycloids of the same magnitude.

6. If the figure be reversed, so that C is the lowest point of the cycloid, and A and B the highest points; then, no friction being supposed, and the cycloid being of resisting matter, a small weight placed at Q will take the same time to slide to C, wherever the point Q may be. Hence all the arcs of the cycloid are said to be *synchronous*.

7. On the same supposition as in the preceding, a weight will slide from B to Q in a shorter time than in any other curve which can be drawn between B and Q. Hence the cycloid is called the *brachystochron*.

Let θ be the angle COP (in theoretical units) [ANGLE], $CM = x$, $MQ = y$, $OP = a$, then we have the following equations:—

$$x = a(1 - \cos \theta)$$

$$y = a(\theta + \sin \theta)$$

from which the properties of the curve may be deduced.

If, instead of measuring PQ from P, we had carried it forward from M, then Q would have described a curve known by the name of the *companion to the cycloid*, but which is in truth a *curve of sines*. [SINES, CURVE OF.]

The history of the cycloid is remarkable from the contests which it produced, and the manner in which the names of Galileo, Descartes, Mersenne, Pascal, Roberval, Wallis, and others, appear in connexion with it. But there would be little use in giving an abstract of history on points of no material use, and the interest of which depends on the light in which a detailed account, and nothing less, would place the state of science of the seventeenth century. Galileo was certainly the first who attempted the investigation of the properties of the cycloid, as appears from a letter to Torricelli, written in 1639. (See Montucla, *Hist. des Math.*, vol. ii. p. 52, &c.)

CYCLO'LITHES. [MADRIPHYLLIÆA.]

CYCLOPÆ'DIA. [DICTIONARY.]

CYCLO'STOMA. [HELICIDÆ.]

CYDER. [CIDER.]

CYDNUS. [ANATOLIA; CILICIA.]

CYDO'NIA VULGA'RIS, or QUINCE, of the fruit of which there are two varieties, apple-quince and pear. The seeds are the part used in medicine, on account of the mucilage which they yield. The seeds are more numerous in the small hard than in the large fleshy fruits. They generally occur in large irregularly-shaped masses, as they easily adhere to each other, owing to the mucus which invests them. When moistened in the mouth or in water, they give out a large

quantity of mucilage, which is white, and not coagulable by boracic acid. One part of these seeds will render 40 to 50 parts of water so mucilaginous, that it will possess the thickness of a syrup. They should be set to digest in cold water, otherwise the mucilage acquires the odour of hydrocyanic acid. Indeed the actual presence of, or tendency to form, hydrocyanic acid, may be demonstrated by distillation. (Stockmann.) Many seeds yield a yellow-coloured mucilage. If allowed to remain in a fluid state the solution soon spoils, but by careful evaporation the mucilage may be brought to a dry state; or, as proposed by Zier, the mucilage may be precipitated from its watery solution by alcohol. Ten ounces of seeds yield two ounces of dried mucilage, two grains of which, with distilled water, produce one ounce of mucilage of proper consistence for use. In whatever way obtained, the mucilage possesses demulcent qualities, and may be employed either internally, or as a lotion, which is especially applicable to the faces of those who suffer from the cold winds of winter and spring.

CYGNUS (the swan), one of the old constellations of Aratus, who refers it to the fable of Leda, as does Higinius; but the latter gives another fable of the same kind. The bright star (Deneb), α Cygni, may be seen on the meridian at eight o'clock in the beginning of October; the bright stars in Aquila, Lyra, and Cygnus form a remarkable triangle.

The principal stars are as follows:—

CYGNUS. [SWAN.]

CYLINDER, in mathematics ($\kappa\acute{\iota}\lambda\iota\nu\delta\rho\omicron\varsigma$), a name given generally to the surface formed by a straight line which moves parallel to itself; whatever may be the guiding curve; but frequently confined to the common definition, which supposes the straight line to be of finite length, and to move round the circumference of a circle, keeping always at right angles to its plane. We shall extend this a little, and treat of the cylinder which has an oval for its base, and the moving line at right angles to the plane of the base, whence the cylinder is called a *right cylinder*.

The cylinder may be considered as a cone, of which the apex is at an infinite distance; and many of the general notions in the article CONE may be applied to it.

The content of a cylinder (in cubic units) is the number of square units in the base multiplied by the number of linear units in the altitude. Thus the cylinder being circular, the base having a radius of 10 feet, and the altitude being 7 feet, the number of square feet in the base is $100 \times 355 \div 113$, or 314.59 , which, multiplied by 7, gives 2202.13 , the number of cubic feet in the cylinder. To find the number of square units in the surface, multiply the number of linear units in the circumference of the base by that in the altitude. Thus in the preceding case the number of feet in the circumference of the base is $20 \times 355 \div 113$, or 62.918 , which, multiplied by 7, gives 440.426 , the number of square feet in the cylindrical part

of the surface, exclusive of its two terminating planes.

[PRISM, SUBCONTRARY.]

CYMATIUM. [COLUMN.]

CYMBA. [VOLUTIDÆ.]

CYMBALS (κύμβαλον), metallic musical instruments of percussion, which are traceable to the remotest ages of antiquity, and, with no great change in form, are still used by the moderns. They are always in pairs, are made of brass, and, according to Greek sculptures and medals, antiently took, as their name imports, a more cup-like shape than at present. Servius says that the cymbals were consecrated to Cybele—that is, were employed by her priests—because they represented the two celestial hemispheres which surround the earth. They are now nearly flat, about twelve inches in diameter, the central part sunk in, and at the back of the sunken portion is a strap, by which each instrument is held. The sound is produced by striking them more or less violently together, and in the open air they produce a very martial effect, but are entirely out of place in the theatre and concert-room. Into the latter, indeed, they have not yet often intruded, but in modern theatrical music they take a prominent part, the composer now making up by noise what he wants in genius and taste.

CYMBU'LIA. [THECOSOMATA.]

CYME, an irregular kind of panicle, having a corymbose appearance, and in which each branch is stopped in its growth after producing a single flower, when it is forced to form lateral branches, which are themselves stopped after forming one flower. The common Laurustinus or the Elder-bush offer examples of this sort of inflorescence.

CYMODOEIA. [ISOPODA.]

CYMO'THOA. [ISOPODA.]

CYNANTHUS. [HUMMING BIRDS.]

CY'NARA, a genus of Compositæ, in many respects like the thistle, but having an involucre composed of thick fleshy spiny scales, and a remarkably thick fleshy receptacle, covered over with numerous bristles. The two species most known are the Artichoke and the Cardoon.

C. Scolymus, the artichoke, so long cultivated in our gardens as a vegetable, came originally from the south of Europe, and though it has long been cultivated in the regions of the north, it does not resist the very severe cold of winter. Its perennial root is thick, fleshy, hard, branching, and gives rise to a cylindrical, glabrous, rather branching stem, from two to three feet high, to which are attached very large pinnatifid leaves, of a pale green above, whitish beneath, deeply serrated in lobes, and irregularly toothed. The heads stand singly at the top of the ramifications of the stem; they are as large as the doubled fist; their receptacle is very thick, fleshy, concave, furnished with simple bristles; the leaflets of the involucre are broad, thick, and terminated in a spiny point. All the florets are hermaphrodite and of a clear violet colour; the tube of the corolla is very long; its limb has five very narrow segments; the staminal tube is very prominent, of the same colour as the corolla. The pappus is sessile and feathery. The root of the artichoke is rather bitter, the stem still more so. It was formerly employed as a diuretic, but it has long been cultivated only as a kitchen garden plant. Everybody knows that the heads of the plant are gathered before the expansion of the flowers, and that the receptacles or the base of the involucre scales are eaten, either raw or after having been boiled in water. The artichoke when cooked is an agreeable food, not very nourishing perhaps, but easy to digest. The receptacles, or artichoke bottoms, may be preserved for winter use by drying them after having blanched them in boiling water.

C. Carduncellus, the Cardoon. The country of the cardoon is the same as that of the artichoke; it is found in the southern countries of Europe and in the north of Africa. Its thick and fleshy leaves cut into spiny lobes with very prominent ribs, its more slender stems terminated by heads of flowers three or four times smaller, with a thin receptacle, and the scales of the involucre armed with sharp spines, easily distinguish it from the artichoke. Some authors, however, have endeavoured to prove that the artichoke is only a variety of the cardoon. This opinion, however, does not appear well founded; for if it were so, among the great quantity of cardoons that are cultivated in gardens some plants would be found transformed into artichokes, which has never happened. In this species it is the rib, or the middle nerve of the leaves, which is eaten. When cooked it is tender, and its flavour greatly

resembles that of the artichoke. It is in general a choicedish, and seldom seen except at the tables of persons in easy circumstances.

CYNAREÆ. [COMPOSITÆ.]

CYNAROCÉPHALÆ. [COMPOSITÆ.]

CYNARRHODON, a name given sometimes to the hip of the rose, which is a fruit composed of a succulent calyx-tube enclosing a number of hard dry hairy nuts.

CYNICS, the name of a sect of Greek philosophers who were produced by the school of Socrates, and were so called according to one interpretation of the word (κυνικοί, dog-like) from their snarling disposition, though it is possible that the name may have been derived from the gymnasium called Cynosarges, in which Antisthenes, the founder of this school, used to lecture. [ANTISTHENES.] Their doctrines were the exact opposite of those of the Cyrenaics, who were also an offshoot of the Socratic philosophy. [CYRENAICS.] They held that virtue was not only the highest but the only object at which men ought to aim, and that most of the sciences and arts, as they do not tend to make men virtuous, but sometimes on the contrary interfere with the attainment of it, are unprofitable and pernicious. The true philosopher, according to their notions, was he who could discard all the comforts and charities of life and triumph over his bodily wants, so as to be enabled to live only for virtue without any interruptions either to the contemplation or the practice of it. The result of these principles was great strictness of morals, and voluntary penances worthy of the fanaticism of an eastern dervise; and as long as these characteristics were coupled with ability in the professors and consistent philosophy in what they taught, the sect maintained its place by the side of other philosophical systems, and some members of it, for instance Antisthenes and Diogenes, deserved and obtained great celebrity. [DIOGENES.] At length, however, the morality of the Cynics degenerated into the most shameless profligacy (see the case of *Crates* and *Hipparchia* in Diogen. Laërt., vi., § 97), and they became so disgusting from their impudence, dirty habits, and begging, that they ceased to be regarded with any respect, and the sect dwindled away into obscurity. Of their speculative opinions we know very little: indeed it does not appear that they had any theories except on the science of logic. The great merit of the Cynic philosophy was that it paved the way for the establishment of Stoicism, which succeeded and superseded it, just as the philosophy of Epicurus supplanted that of Aristippus. The connexion of this school with the philosophy of Socrates appears to have consisted in their developing the idea of science as applied to morality (to which object the labours of Socrates were mainly directed), but they did so to the exclusion of all those other principles which Socrates admitted as useful adjuncts, and his sneers at the austerity and affected negligence of Antisthenes may be taken as a proof of the low opinion which he entertained of this narrow application of his doctrines. (Diogen. Laërt., vi., § 8; ii., § 36.) The classical reader will find in Lucian's *Cynicus* an attempt to justify some of the peculiar views of this school, especially in regard to their neglect of the conveniences of life, though it is not to be supposed that Lucian was inclined to the Cynical philosophy, for he elsewhere ridicules it. (See the *Lapithæ* and the *Vitarum Auctio*.)

CYNICTIS (Zoology), a genus of *Carnivora* established by Mr. Ogilby for a mammiferous quadruped connecting the family of the *Civets* with that of the *Dogs*.

Generic character. Dental formula:—incisors, $\frac{6}{6}$; can-

nines, $\frac{1-1}{1-1}$; molars, $\frac{6-6}{5-5}$. Of these last the three first are spurious, the fourth is the carnassier, and the rest are tuberculated. Feet, digitigrade; toes, 5-4, with long falcular claws adapted for digging. Tail, long, bushy.

'This system of dentition,' says Mr. Ogilby in his paper in the 1st volume of the 'Zoological Transactions,' 'is, in most respects, extremely similar to that which is common to the *Viverræ* in general, and particularly to the genus *Herpestes*, from which the *Cynictis* differs principally in the absence of the rudimentary false molar of the lower jaw, in having that of the upper jaw in contact with the caninae, and in a few other circumstances of very minor importance when compared with the general character of the organization. From the *Ryzæna* or *Suricate*, on the other hand, the dental system of *Cynictis* differs in the

presence of the superior rudimentary false molar, being thus directly intermediate, in point of dentition, between this genus and the *Herpestes*; and it is not a little singular that it should bear precisely the same relation to both these genera in the form and number of its toes. The *Herpestes* have rudimentary false molars both in the upper and under jaws, and five toes both before and behind; the *Cynictis* has rudimentary false molars only in the upper jaw, five toes on the fore and only four on the hind feet; the *Ryzæna* has no rudimentary false molars in either jaw, and four

[Skull of *Cynictis*]

a, seen from above; *b*, profile of the same; *c*, half of cranium seen from below, showing the position of the teeth in the upper jaw. *d*, half of the lower jaw seen from above (from Mr. Ogilby's figure)

toes only, as well on the anterior as on the posterior extremities. These traits of zoological character strongly point out the true natural relations of all these animals, and demonstrate the relative positions which they occupy in the system of nature. With the single exception of the *Proteles*, there is no other known genus of the *Viverra* family which possesses the same number of toes and complete digitigrade extremities which form so prominent a character in the *Cynictis**. Here however all analogy ceases between these two genera. It is true that we are at present ignorant of the adult characters of the dentition of the *Proteles*; when we become better acquainted with this important part of its organization, we may perhaps discover additional points of relation between it and the present genus; but in all its most striking external characters it is completely different, and seems to occupy an intermediate station between the *Dogs*, the *Civets*, and the *Hyænas*. In addition to these characters the *Cynictis* may be readily distinguished by its external form and appearance from all conterminous genera. It has a short head, contracted suddenly in front of the eyes, and forming a small naked muzzle, divided by a longitudinal furrow; the ears are short and elliptical, naked inside, and directed forwards; the body long and slender; the tail bushy, and two-thirds of the length of the body, and the whole external form and appearance not unlike that of a *Ferret* or *Ichneumon*. The temporal fossæ are separated from the orbits by a complete rim of bone.

Example. *Cynictis Steedmannii* (Ogilby), named after Mr. Steedman, to whom zoologists are indebted for a knowledge of the animal.

Description.—Length of the head from the muzzle to the root of the ear, $2\frac{1}{2}$ inches; length of the ear, $\frac{3}{4}$ of an

inch; breadth of the ear, $1\frac{1}{2}$ inch; length of the body from the muzzle to the root of the tail, 1 foot 6 inches; length of the tail, 1 foot; height at the shoulder, 7 inches; height at the croup, $7\frac{1}{2}$ inches. Hair moderately fine in quality, much resembling that of a dog, smooth and close on the body, long and bushy on the tail. The general colour, as well as the whole external appearance, precisely that of a small *Fox*, bright red over the entire body, head, and extremities, deep and uniform on the back, but mixed with silvery grey on the cheeks, neck, sides, and tail, arising from a mixture of hairs tipped with grey, and dispersed through the fur of these parts. The breast, belly, and legs, unmixed red; and the tail, which precisely resembles the brush of a fox, covered with long bushy hairs of a sandy red colour at the roots, dark brown in the centre and grey at the points: the last two inches at the tip of the tail uniform dirty white. Hairs of the body not annulated as in *Herpestes* and the *Suricate*, and altogether of a finer and more furry quality. External form and appearance comparable with those of the *Ferret* and *Egyptian Ichneumon*, but probably standing higher on the legs as being more completely digitigrade.

Locality.—Uytenhage, on the borders of Caffraria. (Ogilby.)

Mr. Ogilby thus concludes his observations on this interesting animal:—"In consulting the works of travellers through the colony of the Cape of Good Hope, I have been able to find but two notices which seem clearly to refer to this animal; one by Dr. Sparrman, the other by Mr. Barrow. The first of these authors in the English translation of his 'Travels,' vol. ii. p. 184, has the following passage. "Two other small animals, which probably likewise belong to the *Viverra* genus, I had only a hasty glimpse of in this colony. The one we saw and gave chase to between the two Fish Rivers made its escape from us, however, by running into a hole underground, and seemed to be somewhat less than a cat, though longer in proportion. The colour of it was a bright red." It is true that this passage records no observation by which we can with certainty refer the animal to which it alludes to, the *Cynictis Steedmannii*, but the size, colour, and habitat are so perfectly similar in both cases, as to render their identity extremely probable. In the following extract however from Barrow's Travels, vol. i. p. 185, the characters are fully reported. "Upon these parched plains" (those of Camdebo, on the eastern confines of the colony) "are also found several species of a small quadruped which burrows in the ground, and which is known to the colonists under the general name of *Meerkat*. They are mostly of the genus of animals to which zoologists have given the name of *Viverra*. An eagle making a stoop at one of these, close to where we were passing, missed his prey, and both fell a sacrifice, one to the gun, the other to the dogs. Both the bird and quadruped appeared to be undescribed species. . . . The *Viverra* was wholly of a bright chestnut colour; the tail shaded with black hairs, bushy, straight, and white at the extremity; ears, short and round; on the fore-feet, five, and on the hind, four toes; the body and tail each one foot long." "There can be no doubt," continues Mr. Ogilby, "of the animal to which this description refers, a description more minute and accurate than we generally find in the works of travellers. It agrees in every point with the species which forms the subject of the present memoir

[*Cynictis Steedmannii*, from Mr. Ogilby's figure.] *

* N. B. *Cryptoprocta*, Benn., described subsequently in 'Zool. Trans.' has five toes and claws on each foot. [VIVERRIDÆ.]

* Mr. Gray informs us that this animal has been described by Cuvier as *Herpestes penicillatus*, and by Mr. Smith as *Herpestes Levaillantii*

except, perhaps, in the reported dimensions of the tail and body; but this difference most probably arises from the age or sex of the specimens, or from the measures of Mr. Barrow being taken in a straight line, whilst mine followed the different curvature of the head, neck, and body. The name, *Meer-kat*, by which it appears this animal is known to the colonists, signifies a monkey, and is of very general acceptance in South Africa, being applied indifferently to the present species, the *Cape Herpestes*, *Ground Squirrels*, and various other small burrowing animals. Both the passages here quoted confirm the burrowing habits of the *Cynictis Steedmannii*, which I had already inferred from the form of the claws.

CYNIPS QUERCUS. [GALLS.]

CYNOCE'PHALUS. [BABOON, vol. iii., p. 227.]

CYNOMORIA'CEÆ, an obscure order of Rhizanth, distinguished from Balanophoraceæ by their distinct stamens, and the imperfect perianth of the male flowers. The order is represented by *Cynomorium coccineum*, the Fungus melitensis of the old herbalists, a plant once in repute for its astringent properties, but now valued only for its rarity and the botanical interest that attaches to it. Dr. Walsh tells us that 'it grows most plentifully on a detached rock on the south-west side of the island of Gozo. It is there much celebrated for its medicinal properties: the time of the discovery of its virtues is not known, but, from some antient MSS., it appears to have been at a very remote period. It had been the usage of Malta to banish to Gozo all females of dishonest character, and here, according to tradition, they found a vegetable substance of an astringent quality, which proved very efficacious in removing the consequences of their irregular life. It was prepared in earthen pots, some of which have since been dug up in various places, marked with Phœnician characters indicating their use. The plant was also applied by them to the purposes of divination. It was laid between the breasts, and, from some accidental circumstances of position, &c., they augured good or bad fortune. This practice was reprobated, and said to be finally abolished, by a Capuchin missionary. This curious vegetable was subsequently esteemed as a remedy in dysentery, and its curative powers were long held in very high repute. About the year 1740, the Knights of Malta set such a very high value on this fungus, that they interdicted the approach of any person to the place where it grew, and guarded the passage with the strictest jealousy. In April, when the fungus was ripe, it was carefully gathered by persons appointed for that especial duty, and the precious morsels were deposited in a government office, from whence some portions were sent as presents by the grand-master to different sovereigns, and the remainder distributed among the hospitals of the island. Even after the English took possession of Malta, and succeeded to the territorial rights of the order, and, amongst other things, to the possession of this rock, a *custode* was appointed to take care of it as heretofore, with a salary, which always makes an item in the public accounts of Malta. The fungus is thus continued to be guarded and regularly gathered, deposited in the state-office, and distributed among the hospitals; and when Dr. Hamilton, through the kindness of an official person in Gozo, was permitted to visit this rock, he was accompanied by the *custode*. The rock, as shown by the doctor's sketch, is difficult of approach: it is an isolated precipice, about 600 feet in height, detached from the neighbouring shore, and presenting very steep and inaccessible sides, in some places projecting considerably over the sea, so that the circumference of the base is less than that of the upper parts. It stands on the verge of a noble circular basin, formed by the surrounding cliffs, into which the sea enters by the chasms at each side of the fungus rock, the whole presenting the aspect of the crater of a volcano, raised from beneath, or extinguished by the irruption of the sea.'

CYNOSU'RA (κυνὸς ῥά, the tail of the dog), a name given to the lesser Bear. According to Aratus and Hyginus, Cynosura was one of the nymphs of Mount Ida, who nursed Jupiter. But it is at least as probable that before the Greeks adapted their mythology to the constellations, they had from some oriental source the habit of figuring Ursa Minor as a dog, and that the tail of the dog was the pole star. [URSA MINOR.] Many persons may probably know this word only from the two lines of Milton's *Allegro* —

Where perhaps some beauty lies,
"Æ Cynosure of neighbouring eyes.

These lines have puzzled many, though the reference to the pole star and the property of the magnet gives the image a degree of fitness for poetry which the etymology of the word alone would hardly suggest.

CYNOSU'RUS CRISTA'TUS, a well-known pasture grass, called by farmers crested dogtail or gold-seed, exceedingly abundant in all natural and artificial grass land. It grows with a slender smooth stem to the height of one or two feet, and is terminated by a somewhat cylindrical spike-like panicle of short clusters of flowers; each cluster consists of two flowered spikelets resting upon pinnate bracts. The glumes are two, about the length of the florets; the paleæ 2, of which the lowest is sharp-pointed. The styles are feathery; the fruit is a small, yellow, smooth-shining seed-like body, whence the common name of gold seed.

Although this grass forms so constantly a portion of all good pastures, it is chiefly on account of the fineness and closeness of its herbage that it is valuable, the quantity of hay that it produces being inconsiderable. Mr. Sinclair hence observes, that 'it is inferior for the purposes of hay, but admirably adapted for permanent pastures. The roots penetrate a great way under ground, from which circumstance it remains green after most other grasses are burnt by a continuance of dry weather. In irrigated meadows it arrives at a greater size than in any other situation.'

[Cynosurus cristatus.]

CY'NTHIA (Zoology), one of the subgenera into which Savigny has divided the *Ascididæ*. The subgenus *Cynthia* consists of those ascidians whose body is sessile, and which have the branchial sac plaited longitudinally, and the reticulation continuous. Their external envelope or test is coriaceous. The structure comes nearest to that of *Boltenia*. [BOLTENIA.] Example, *Cynthia Momus*. This Ascidian does not attach itself to rocks, but makes shift to float about in the Gulf of Suez by attaching itself to fuci and other submarine plants. (See Savigny's *Mémoire sur les Animaux sans Vertèbres*, Paris, 1816; and Mr. W. S. Macleay's 'Anatomical Observations on the Natural Group of Tunicata,' *Linn. Trans.*, vol. xiv. p. 527.) N. B. M. Latreille has used the term *Cynthia* to distinguish a genus of coleopterous insects.

CYPER'ACEÆ, an extensive natural order of glumaceous Endogens, having much the appearance of grasses, with which they are sometimes popularly confounded. They differ in their stems being usually solid, not hollow, and angular, not round; in the sheaths of their leaves not opening on one side, but forming perfect tubes when the stem is pulled through them; in their male florets having no paleæ nor any covering to the stamens except a single bract, while the bisexual florets have nothing more than a few hypogynous bristles superadded; and finally in their embryo being enclosed in the albumen, and not lying at one side of it. There are other distinctions besides these, but what have been mentioned are the most remarkable. A large proportion of the order bears the name of sedges, and hence the sedge family or tribe is given to these plants as their English appellation. They are mostly inhabitants of marshy or swampy grounds, a few are met with on dry upland pastures, and a good many are Alpine plants. They

occur in all parts of the world, and are generally abundant; but little or nothing has been discovered of their uses; their most common application is to the manufacture of what are called erroneously rush mats and rush bottoms for chairs. The plant used in this country for such purposes is not any kind of rush, but the cyperaceous species, *Scirpus lacustris*. It is not a little remarkable, that nearly as these plants are allied to grasses, they scarcely at all participate in the nutritious quality of that useful order; it is only among the coarse bad herbage of marshes that they are allowed to form a constituent of hay.

[*Cyperus fuscus*.]

1, a spikelet magnified; 2, a flower with its bract; 3, a fruit; 4, a section of a seed.

CYPRÆIDÆ. *Cowry Family.* Cowries, or sometimes, *Gowries*, *Porcellanen* of the Germans, *Porcelaines* (Porcelain shells) of the French. A family of marine gastropodous mollusks, well known in commerce from one of the species (*C. Moneta*) being used in some parts of the East as a circulating medium. [COWRY.]

Family character. Animal unisexual, elongated; head, distinct, with two conical or subulate *tentacula* of some length, at the external base of which are situated the two sessile *eyes* on small projections; *mouth* vertical, at the bottom of a small cavity, and containing a lingual riband, or lamina, beset with tentacles and prolonged in the abdomen. *Branchial cavity* open, situated near the back of the neck; gills arranged in a longitudinal pectinated series on the inside of the columella on the left side of the mantle; siphon very short, and formed in the mesial line by the edges of the two lobes. *Mantle* bilobed, the lobes very large with extended aliform edges, capable of being reflected over the back of the shell so as to join on the mesial dorsal line. *Foot* oval, elongated, very large. *Vent* at the extremity of a tube behind the branchial cavity. *Male organ* situated more forward, and communicating with the orifice of the deferent canal by means of a furrow. *Adult shell* involute, highly enamelled, oval or oblong, more or less rounded or cylindrical with a small and imbedded spire; aperture longitudinal, nearly straight, toothed, or plaited, on each side, with a channel or groove at each end, inner lip flattened or sub-concave, outer lip involute. No operculum.

[*Cypræa (Trivja) Pediculus*.]

a, the animal seen from above; b, side view of the same.

Mr. Gray, whose arrangement we select, as being, in our

opinion, the best which has hitherto appeared, thus notices the very great change of form that the young shell undergoes in its progress to perfection. 'The shell alters its appearance considerably, according to the age of the individual, and exhibits three very distinct stages. In the young or first stages, which are figured in 'Ency. Méthod.,' t. 349, f. a. b., 'Mus. Gotwald,' viii. t. 53, b. e. 65, a. f. 66, a. c.; the shell is generally smooth, of a plain greyish colour, or with three longitudinal bands, and the upper part of the *inner lip* is smooth, convex, the lower part flat or concave; the *outer lip* thin. In the second stage the shell begins to assume more the character of the genus, as the outer lip begins to be inflected or rather thickened, and approaches nearer the perfect appearance of the species as the second coat of colour is deposited; but differs from it in the want of thickness of the shell and the spire being more distinct, and in the want of the dorsal line, which is usually distinct in the third or perfect state, where the last coat has been deposited*, and

[*Cypræa Exanthema*, illustrating the stages of growth.]

a, young shell in the first stage seen from above: view of the back; b, the same showing the columella and the thin edge of the outer lip; c, an advanced stage; view of back. The apex is already sinking, and the thickened lips are formed; d, still further advanced: the mantle has begun to secrete the enamelled spotted coat on the side, but the transverse stripes are still visible; e, the perfect shell; all traces of the transverse stripes lost under the enamelling of the thickened spotted coat; f, view of under side of the perfect shell.

* By the mantle.

the aperture is more plaited on both sides. The colouring, or at least, the disposition of the colouring here, is a much more certain characteristic of species than either the general outline of form or size, the latter of which is exceedingly various. In this family I have often observed full-grown specimens of *C. Arabica* from one to three inches long; this peculiarity is attempted to be explained by Lamarck and others, who assert that when the animal has formed a complete shell, as it has not the faculty of enlarging its size, it is obliged to quit its shell and form a new one, in the same manner as the *Annulosa* cast their skins, and by that means the same animal forms many shells; but I believe there is not the slightest ground for this notion.

Mr. Gray has recently observed, that sometimes, though rarely, the young shells of *Cypræa*, especially *C. Arabica*, have the inner edge of the outer lip thickened and furnished with a compressed sharp-edged series of teeth.

Geographical Distribution, Habits, &c.—*Cypræidæ* abound both in the old and new world, but their greatest development both in point of size and number of species takes place in warm climates. A very few species are inhabitants of the European seas. The family are littoral, and are generally found under stones or rolled corals.

Genera CYPRÆA (Cowry).

Generic character.—The young shell smooth, the adult with both lips toothed; the anterior and posterior canal distinct, recurved; the front end of the columella lip smooth, edged by a single large oblique fold, separated from the teeth by a deep groove. (Gray.)

*

Sub-genus. 1.

Cypræa.

The front of the columella broad, deeply impressed; shell mostly smooth.

a.

Shell smooth; columella-pit transversely ridged; teeth of inner lip generally long. (Gray.)*

Under this division of the sub-genus Mr. Gray arranges twenty-seven species, including some of the rarest forms,—*Cypræa Aurora* (the Morning Dawn, or Orange Cowry), and *Cypræa Princeps*, for example,—together with *Cypræa Tigris* (the Tiger Cowry), and other common species.

Example.—*Cypræa Mappa*, the Map Cowry.

Description. Shell more or less ventricose, ovate, varied with deep brown or yellow lines, and spots. Dorsal line lacinated. Margin thick, spotted with black; teeth yellow. Locality, Indian Ocean.

[*Cypræa Mappa*.]

a, seen from above; b, seen from below.

There are many varieties, among which the rosy variety, the dark variety, from the Pearl Islands; the citron variety; and the dwarf rich-mouthed variety from the Mauritius, are the rarest or most beautiful. The young shell is of a fawn colour with obsolete spots and dashes.

β.

Shell smooth; columella pit (nearly) smooth; teeth of inner lip short or indistinct.

Under this division of the sub-genus Mr. Gray arranges fifteen species.

* The descriptions are throughout almost entirely Mr. Gray's, as well as the arrangement.

Example.—*Cypræa Talpa*, mole cowry; *Sardonix Cowry* of Gray.

Description.—Shell oblong ovate, subcylindrical, yellowish, with three darker bands; the subangular base and teeth brown or black; mouth pale. There is a variety (*Exustus*) shorter, darker, and with the teeth smaller and closer.

[*Cypræa Talpa*.]

γ.

Shell with the back warty (rarely smooth), base ridged. Under this section Mr. Gray enumerates three species.

Example.—*Cypræa Cicercula*, Vetch Cowry.

Description.—Shell subglobose, yellow, brown dotted, with a dorsal groove, and scattered tubercles over each extremity; base four-spotted, partly grooved.

[*Cypræa Cicercula*.]

a, seen from above; b, seen from below.

There is a larger variety which is more oblong, smooth, and is without the dorsal groove (*C. Globulus*).

δ.

Shell with transverse ribs.

Only two species are enumerated by Mr. Gray, and one of these, *C. rugosa*, Brod., is fossil.

Example.—*Cypræa Childreni*, Children's Cowry, Gray.

[*Cypræa Childreni*.]

a, seen from above; b, seen from below.

ε.

Shell with longitudinal and transverse ribs.

One species only, *Cypræa Adamsonii* Gray; Adamson's Cowry, very rare.

Description.—Shell ovate; pear-shaped, white, brown mottled. Locality, Pacific Ocean? (Gray).

[*Cypræa Adamsonii*.]

* *

Sub-genus 2.

Arcaia.

Front of the columella flat, or nearly so; back of shell smooth.

a.
Margin of the shell pitted on the upper edge. Fourteen species.

Example.—*Cypræa guttata*, Gmel. Blotched Cowry, Gray.

Description.—Brown, pale spotted, base and margin white, brown-ridged: a beautiful and rare species. Locality, Red Sea? (Gray).

[*Cypræa (Aricia) guttata*.]

β.

Margin entire; teeth of both lips extended more or less over the base. Thirty-seven species.

Example.—*Cypræa Moneta*, Linn. Money Cowry.

Description.—Shell yellow or white, with a yellow ring; margin and base tubercular; teeth of inner lip moderate.

Varieties.—*a.* Without a ring; *b.* with the margin and base less tubercular. [Cowry.]

Young.—Whitish with two dark bands. (*C. icterina*, Lam.)

[*Cypræa (Aricia) Moneta*.]

a, adult; *b*, young.

γ.

Margin entire; teeth of inner lip very small, forming a slight ridge; front of columella lip slightly concave, produced, and toothed internally. Two species.

Example.—*Cypræa angustata*, Gray.

Description.—Shell whitish brown, minutely brown dotted; base white; margin closely black dotted, ends blackish. Worn plain brown, varying in darkness. Locality, New Holland.

[*Cypræa (Aricia) angustata*.]

Sub-genus 3.

Naria.

Front of the columella narrow dilated into a sharp-toothed ridge; shell smooth.

One species only, *Cypræa irrorata*, Gray.

Description.—Shell ovate, purplish, yellow dotted; base white, flat; teeth large. Locality, South Seas. Most allied to *C. Felina*, variety 1.

[*Cypræa (Naria) irrorata*.]

LUPONIA.

Shell like Cowry, but front end of the columella lip crossed by several irregular ridges, without any distinct marginal one, internally narrow, flat; shell pear-shaped, smooth, or cross-ribbed.

Five species. Example, *Luponia Algoensis*, Algoa Lupon, Gray.

Description.—Shell pale, brown dotted; base smooth; teeth of inner lip very small; margin black dotted. Variety with the teeth more or less obliterated. Locality, Cape of Good Hope.

[*Luponia Algoensis*.]

CYPRÆOVULA.

Like Cowry, but front end of columella covered with regular cross-ribs, like rest of base, internally produced into an acute-toothed ridge. Shell pear-shaped, cross-ribbed.

One species, *Cypræovula Capensis*, Cape Cypræovula, Gray.

Description.—Pale brown; ribs very thin, continued, sharp. Locality, Cape of Good Hope: very rare.

[*Cypræovula Capensis*.]

TRIVIA.

Like *Cypræovula*, but front of columella internally concave, ribbed. Shell subglobular, cross-ribbed.

a.

Mouth wide; outer lip slightly inflexed; shell equally ribbed.

Five species. Example, *Trivia carnea*, Flesh-coloured Pig, Gray.

[*Trivia carnea*.]

Description.—Shell oblong, thin, pellucid, pure rose-coloured, with very thin, distant, continued ribs; lips whitish. Varies with an indistinct dorsal groove.

Mr. Gray observes, that *Pig* is the common name of these shells on the coast, and that they are called *Porcelli* in Italy. He adds, that *Porcellain*, the common name for

Cowries, is taken from the fancied resemblance of these shells to pigs, and refers to *Fabius Columna*, &c.

β.

Mouth narrowish; outer lip wide; ribs of back subequal, linear.

Eighteen species. Example, *Trivia Europæa*, *European Pig*, Gray; *Cypræa Europæa*, Lam.

Description.—Shell ovate, subglobose, ash or flesh-coloured, with three black dots, and a whitish dorsal streak; ribs close, rather thick, whitish; base white; outer lip wide.

Variety.—Back spotless, with an indistinct dorsal groove. (*Cypræa Arctica*, Mont.)

Young white and smooth.

[*Trivia Europæa*.]
a, adult; b, young.

γ.

Mouth narrowish; the outer lip arched; the ribs enlarged or tubercular near the dorsal groove.

Seven species. Example, *Trivia Pediculus*, *Louse Pig*, Gray; *Cypræa Pediculus*, Linn.

Description.—Shell ovate, pale reddish, with six square, black, dorsal spots; ribs rather thick, subrugose, crowded; dorsal line narrow; base reddish. Locality, West Indies.

[*Trivia Pediculus*.]

δ.

Mouth narrow; ribs tubercular; dorsal line distinct; front of columella smooth.

Two species. Example, *Trivia pustulata*, *Pimpled Pig*, Gray; *Cypræa pustulata*, Lam., commonly called by collectors the Small-pox Cowry.

Description.—Purplish-brown; ribs studded with red-brown, black-edged warts. Locality, Pacific Ocean.

[*Trivia pustulata*.]
ERATO (Risso).

Spire conical; apex sub-mamillary, blunt; shell, when young, smooth; the adult with both lips finely crenulated; the columella concave slightly radiately plaited or smooth, with two or three folds in front; the anterior canal straight, the hinder indistinct.

Seven species. Example, *Erato scabriuscula*, *Roughish Tear-shell*, Gray; *Marginella Cypræo'a*, Sow.

Description.—Shell ovate, turbinate, livid, purplish, minutely tubercular; spire conical; dorsal line impressed; mouth wide, whitish, inner lip largely plaited its whole length; teeth large, young, smooth; lip thin, toothless. Locality, South Pacific, St. Elena.

[*Erato scabriuscula*.]

OVULUM (*Ovula*, Lam., commonly called Poached Eggs).

Generic Character.—The shell, when young, spirally striated; when adult, covered with a smooth enamelled coat; the inner lip toothless; the outer toothed or crenated; the anterior and posterior canal more or less elongated.

α.

The outer lip broad, inflexed, rounded, crenulated; extremities short; front of columella rounded.

Of this subdivision Mr. Gray enumerates two species. Example, *Ovulum ovum*, *Ovula oviformis*, Lam.; *Bulla ovum*, Linn., *Common Poached Egg*.

Description.—White; back rounded; inside orange-brown.

[*Ovulum ovum*, adult.]

β.

Outer lip inflexed, broad, toothed; ends short, curved; hinder end with a tooth on the inner side; front of the columella expanded beneath.

One species only, *Ovulum verrucosum*, *Ovula verrucosa*, Lam.; *Bulla verrucosa*, Linn.; *Two-warted Poached Egg*, Gray.

Description.—Shell ovate; back angular; extremity rosy, with a depressed wart above. Young closely striated; ends brown-edged. Locality, Indian Ocean.

[*Ovulum verrucosum*.]

γ.

Outer lip inflexed, rounded, narrow, toothed; rest like sect. β.

Four species. Example, *Ovulum Margarita*, Sow.; *Pearl Poached Egg*, Gray. Shell ovate, subglobose, white, pointed in front, ventricose; base convex; hinder tubercle rugose; front of columella concave; outer lip rounded. This with

[*Ovulum Margarita*.]

six brown dots artificially made is *Ovula punctata* of Duclos, Bull. Sci.; Guerin Mag. 27. Locality, Friendly Islands.

δ.

Outer lip slightly inflexed, narrow, keeled externally, with edge shelving inwards; the rest like the former.

Seven species. Example, *Ovulum pyriforme*, Sow.; *Pear-shaped Poached Egg*, Gray.

Description.—Shell pear-shaped, yellowish-white, attenuated in front; front of columella concave; outer lip shelving inwards. Locality, New Holland.

[Ovulum pyriforme.]

ε.

Outer lip thickened, inflexed, toothless; extremities short: front of the columella flattened; hinder part with a fold, obliterated by age.

Nine species. Example, *Ovulum gibbosum*, *Ovula gibbosa*, Lam.; *Bulla gibbosa*, Linn.; *Gibbous Poached Egg*, Gray.

Description.—Shell oblong, blunt, white; margin yellow, covering nearly the whole shell; back with an angular rib. Varies in length and breadth. Locality, Atlantic Ocean.

[Ovulum gibbosum.]

ζ.

Outer lip thickened, inflexed, toothless, extremities rather elongated; the hinder conical, straight; the rest like the former.

Four species. Example, *Ovulum longirostratum*, Sow.; *Goodhall's False Spindle*, Gray. Shell fusiform, white, thin; beak very long, curved; mouth linear, rather expanded in front. Locality, Adriatic.

[Ovulum longirostratum.]

η.

Outer lip thickened, slightly inflexed, toothless; the front of the columella rounded, the extremities very long. (*Volva*, De Montf.)

One species only, *Ovulum Volva*, *Ovula Volva*, Lam.; *Bulla volva*, Linn., Common Weaver's Shuttle.

Description.—Shell oval, flesh-coloured, striated; outer lip pink; the beaks long, flexuous. Locality, China.*

Place in the Animal Series.—Lamarck places *Cypræa* between *Ovula* (*Ovulum*),—which is immediately preceded by *Marginella* and *Volvaria*,—and *Terebellum*, *Ovulum* being the first genus of his *Enroulées* (Involute Trachelipods). Cuvier arranges the genus between *Conus* and *Ovula*, (which last is immediately succeeded by *Terebellum*), in his third family of pectinibranchiated gastropods or *Buccinoidea*. De Blainville's position for the Cowries is in his third family, *Angyostomata*, of his *Paracephalophora Dioica*,

* The reader should also consult Mr. G. B. Sowerby's monograph of the genus *Ovulum* in his *Species Cochyliorum*.

[Ovulum volva.]

between *Peribolus* (which almost all agree to be a genus established on the young form of *Cypræa*) and *Ovula*, *Peribolus* being preceded by *Marginella*, and *Ovula*, the last genus of his first order, *Siphonobranchiata*, being succeeded by *Trochus*, the first genus of his first family *Goniostomata*, of his second order of *Paracephalophora Dioica*, viz., *Asiphonobranchiata*. Rang, in his Manual, places *Cypræa* (including *Peribolus*) between *Oliva* and *Ovula*. In Deshayes's Tables, the genus stands between *Ovula* and *Oliva*.

Mr. Gray (*Zool. Journal*, vol. i., p. 73) says, 'This family appears to be allied to the subfamily *Cassidæ*, amongst the *Buccinoidea*, by means of the *Cassis Testiculus*, of which Lamarck observes, "ce casque a un peu l'aspect de certains *Cypræa*;" but the affinity is not slight, for in the shape and form of the aperture, which has a groove or canal at each end, both of the lips plaited, and the front part of the columella flattened, it accords with those *Cypræa*; but the outer lip is not inflected, nor is the back of the shell covered with a china-like coat, but with epidermis, and the canal in front of the aperture is recurved. The *Ovulae* on the opposite side the family, have certainly great affinity to the *Bullidae* (*Bullidæ*), as is pointed out by Linnæus, who places them all in that genus, but *Bulla* differs most essentially from them; in the animals by the position of their branchiæ and their being half hermaphrodite, and in the shell by the aperture being rounded and quite entire at each end, and the edges not being thickened, nor the back covered with a shelly coat, for the shell is here covered with the soldered reflected lobes of the mantle; the connexion is most apparent by means of *Ovula patula* and *Bulla Naucum*, in the latter of which there are some slight appearances of a curved canal at each end of the aperture, as in the character of the *Cypræideæ* (*Cypræidæ*), but it has not the enamelled back.

'This family has some analogy in their polished coats, first to the *Marginellæ*, which induced Montagu to call a species of that genus, *Cypræa Voluta*; and, indeed, such is the affinity between the young of this species, which has been called *Bulla diaphana*, that Dillwyn has considered it as the young of *Cypræa Europæa*; in which Montagu appears also to have coincided, until he observed a totally different construction in the animal: but I believe that *M. persicula* is the most analogical species of this genus; and secondly, to the *Olivæ*, which differ essentially in having an operculum, and all the characters of the *Buccinoideæ* (*Buccinidæ*).'

These observations were written before a more extended examination enabled Mr. Gray to propose the natural arrangement including the genus *Ovulum*, which we have given above from his monograph; but we have laid them before the reader because they contain many useful remarks.

FOSSIL CYPRÆIDÆ.

Fossil shells of this family do not appear to have been found below the Supracretaceous group. Mr. G. B. Sowerby speaking of the genus *Cypræa* (Genera) says, 'of these, the fossils, we have several species in Britain, in the London clay and crag; many others are found on the Continent, as in the calcaire grossier in the environs of Paris; at Laugnan, near Bordeaux, and in Normandy; also

in Italy and Piedmont; we have seen specimens of a very fine fossil species, nearly resembling *C. mus*, from the Netherlands: they seem to be confined to the newer formations. Lamarck enumerates eighteen fossil species of *Cypræa*, and two of *Ovulum*. Deshayes, in his Tables, makes the number of living *Ovula* eighteen, and the number of fossil (tertiary) species six. Three species, *O. Spelta*, *O. birostre*, and a new species he makes both fossil (tertiary) and living in the Mediterranean, the Indian Ocean, and the Mediterranean respectively. The number of living species of *Cypræa* he makes 138, and the number of fossil (tertiary) 19. He considers *Cypræa lurida* (Medit.), *rufa* (ibid.), *Annulus* (African Ocean), *Coccinella* (European Ocean), a new species (Sicily), and another new species, *Sphæriculata*? Lam., with an unknown habitat, as both living and fossil (tertiary).

Mr. Gray notes the following as fossil:—

Cypræa.

Cypræa Physis, Brocchi (*C. Pyrula*, Lam.), Plaisantin or Placentin; *C. leporina*, Lam.; *C. gibbosa*, Gray; *C. tumidula*, König, Bordeaux: and he observes, that *C. annularia*, Brogn., appears to be an allied species; *C. fragilis*, Gray; *C. Deshayesii*, Gray; *Ovula tuberculosa*, Duclos; *C. inflata*, Lam., Grignon, allied to *Ovulum*; *C. subrostrata*, Gray, Nehove; *C. fabagina*, Lam.; *C. diluviana*, Gray; *C. rugosa*, Brod., Turin.

Luponia.

L. elegans, Gray; *Cyp. elegans*, DeFr.; *L. dactylosa*, Gray; *Cyp. dactylosa*, Lam.; *Cyp. Gervillii*, Sow.; *Cyp. Georgii*, DeFr.

Trivia.

T. Barcinensis, Gray; *Cyp. Barcinensis*, König, Barcelona; *T. sphæriculata*, Cyp. Lam.? Italy; *T. acuticostata*, Gray, Italy; *T. pediculoides*, Gray, Italy; *T. Porcellus*, Gray, Crag? *T. Bronnii*, Gray, Italy; *T. solida*, Gray; *T. avellana*, Sow., M. C., Suffolk Crag, which, Mr. Gray observes, appears to be an allied species; *T. Duclosiana*, Gray.

Erato.

E. ventricosa, Gray, Italy.

Ovulum.

O. Lethesii (*Leathesii*?), Sow., M. C.

Mr. Gray makes the whole number of species of *Cypræidæ*, including the subgenera above indicated, and the fossil as well as the living species, 174: If *Cyp. nivosa*, Brod., is to be considered as a well-established species distinct from *Cyp. Dama*, as Mr. G. B. Sowerby (*Zool. Journ.*, vol. iv., p. 220) and others contend, the number will be 175, provided *C. Broderipii*, Gray, be not also a variety of *C. Dama*, as Mr. Gray says it perhaps may be. To these are to be added eight living species recorded by Mr. Gaskoin, and one by Mr. Reeve, in the *Zoological Proceedings for 1835*, as hitherto undescribed; and *C. umbilicata*, Sow., provided it be not a variety of *C. pantherina*, as Mr. Gray states it to be, but which Mr. Sowerby does not allow, considering it an established species more nearly allied to *C. pantherina* than *C. Tigris*.

M. Duclos has long promised a monograph of this family, but it has not yet appeared.

CYPRESS. [CUPRESSUS.]

CYPRIANUS, ST., THA'SCIUS CÆCILIUS, one of the most eloquent of the Latin fathers, was archbishop of Carthage towards the middle of the third century. The facts and dates relating to the early portion of his life are stated by different writers with a variation which occasions uncertainty. He was probably born about A.D. 200, at Carthage, where, before his conversion to Christianity, he acquired considerable affluence as a teacher of oratory, then so indispensable to success in all public affairs, from the ignorance of the great mass of the people, and the consequent facility and necessity of operating upon them by rhetorical artifice and arguments addressed to the passions—expedients which Cyprian, in the exercise of his episcopal office, appears to have duly appreciated, if we may judge by the florid style of his declamations, and his frequent recourse to the authority of celestial visions and miraculous events. His career as a Christian appears not to have exceeded ten or twelve years; for it was not until about the fiftieth year of his age that he was gained over to the church of Carthage by Cæcilius, a presbyter, whose name he henceforth adopted. On his conversion, he sold his mansion and estate for the benefit

of the poor, and observed, in his mode of life, the most ascetic severity. It is stated, however, that, from some unexplained circumstance, he afterwards became repossessed of his property. Having held for two years the office of presbyter, to which he was elected on his joining the Christian community, he was importuned by the people to become their bishop, in opposition to several other presbyters who sought the promotion, and he is said to have been shut up in his house by the assembled populace, who barricaded all the outlets to prevent his escape, which in vain he attempted to make at an upper window. He was consequently installed archbishop of Carthage; but the persecution under the Emperor Decius having soon afterwards commenced, Cyprian fled, and so closely concealed himself during about a year and a half, that the place of his retreat appears never to have been known. This flight and long desertion of his flock occasioned much scandal against the church, and caused the clergy of Rome to address those of Carthage on the subject. (*Cypr. Epis.* 2.) The plea anxiously alleged by the archbishop and his apologist Pontius is an especial revelation from God in a vision. ('Deus secedere me jussit,' *Epis.* 9.) That this was a fiction is shown in *Epis.* 5, where one Tertullus is made responsible for the advice ('à Tertullo ratio reddetur'). When the persecution was abated, Cyprian, having suffered only proscription and the confiscation of his property, returned to Carthage, and being reinstated in his bishopric, he held several councils, at one of which 85 bishops attended to legislate concerning the rebaptizing of heretics, apostates, and deserters, who, after escaping the severity of Decius by renouncing their religious profession, desired to be re-admitted into the church. On the renewal of the persecution, about six years afterwards, by the Emperor Valerian, Cyprian was brought before the proconsul Paternus, with nine bishops of Numidia, who were condemned as profane disturbers of the peace, and sent to work in the mines. Cyprian was banished to Curubis, about 40 miles from Carthage. By Galerius, the successor of Paternus, he was restored to his former dignities; but on his refusal to sacrifice to the pagan deities in obedience to the emperor's commands, he was seized by a band of soldiers, and was sentenced to be beheaded as an enemy to the gods, and a dangerous seducer of the people. He was led from the proconsular palace of Sextus to an adjoining field surrounded with trees, which were filled with thousands of spectators, in the midst of whom he submitted with much fortitude to his sentence. That the populace must have experienced a great reversion of sentiment towards their archbishop since they constrained his acceptance of office, is evident from this acquiescence in his death, and from the fact that, previous to this event, they loudly demanded in the theatres that he should be thrown to the lions. This change arose apparently from the harsh and ascetic austerity of Cyprian in denouncing not only idolatry and licentiousness, but the reasonable and natural gratification of the passions.

His writings are numerous and valuable, as containing much curious and important information concerning the doctrines and discipline of the primitive church: they consist of two kinds, epistles, and tracts or sermons. Of the former there are 83, many of which appear to have been written during the eighteen months of his concealment. The following few notices will show the kind of subjects to which these epistles relate. In the one to Donatus he relates, with much rhetorical embellishment, the circumstances of his own conversion, and shows the advantages of monastic seclusion and abstinence. In that to his priests and deacons he gives advice about escaping from persecution. The one to Cornelius contains passages of much importance to the apologists of the church of Rome, in which are mentioned, 'Petri cathedra atque ecclesia principalis unde unitas sacerdotalis exorta est.' The epistle to Fides contains the judgment of Cyprian and a council of bishops in favour of infant baptism. Another to Magnus on the same subject asserts that sprinkling is no less efficacious than dipping. One to Pomponius reproves the licentious abuses of monachism, and the prevalent custom of virgins living with the clergy, ostensibly for pious instruction, but really for indulgence in fornication. An epistle to Cæcilius is important as insisting upon the absolute indispensableness of mixing water with the eucharistic wine. In some ancient MSS. three epistles are given besides the above-mentioned number, one of which, from Pope Cornelius to St. Cyprian, is replete with abuse and insolence.

The following are the principal tracts of Cyprian: *De Lapsis*, that is, concerning those who, from persecution, had lapsed into idolatry. The miraculous stories related in this discourse are such as in the present day would be regarded as pure falsehoods. (See Dr. Middleton's *Inquiry*, p. 112.) *On the unity of the church*: this is a treatise which both from the Roman and English hierarchy has received especial attention. It strongly denounces all schismatic separation, declaring that there is no crown, even for martyrdom, out of the pale of the true church.

The discourse *On Mortality* was written at the time of a dreadful plague, which for several years devastated the Roman empire. It shows the lamentable want of a due estimate of the value of life which distinguished the religious enthusiasm of that age. All here below is represented as a course of unmitigated misery and suffering, felicity being attainable only in heaven above; a Christian, says Cyprian, should therefore be thankful for any kind of death. The *Exhortation to Martyrdom* consists of twelve classes of scriptural passages exhibited to encourage and stimulate the faithful in submitting to tortures and death. The treatise *Against the Jews* is also a series of texts, quoted and verbally applied, as usual at that time, without any regard to the sense of the context. In the tract *On the Dress of Virgins* (*De Habitu Virginum*) many facts are mentioned which illustrate the social state of those times. A severe denunciation is directed against the passion among rich and youthful females for immodest attire, extravagant ornaments, the use of paint and cosmetics, and the dyeing of black hair a flaxen yellow in imitation of the Germans. The immoral habits of unmarried women appear to have furnished an especial subject for the sermons not only of Cyprian, but of all the primitive fathers. Besides a discourse on the Lord's Prayer, which has received high commendation, there are four which are considered to be wrongly ascribed to St. Cyprian; one is a turgid declamation in praise of martyrdom; the second is on Chastity; and the other two against Theatres, and against the heretic Novatian. The style of Cyprian much resembles that of his master and favourite author Tertullian. He treats the same subjects in the same manner, and though his language is more artificial, it is similar in harshness and occasional barbarisms. His eloquence is admired, however, by Jerome and even by Lactantius. In credulity he appears to have had but few equals, if indeed he believed all the miraculous stories he relates; for besides his own continual visions, he seriously appeals not only to the deeds of demoniacs or rather maniacs, and to the dreams of poor and ignorant women, but to the revelations of 'little boys full of the Holy Ghost.' (Epist. 9.) That St. Cyprian's visions happened generally to authorize some act of episcopal power unapproved by his clergy and people is indeed a fact which cannot but suggest a doubt of their reality.

There are several good editions of his works, among which may be mentioned that of the 'Opera Omnia,' Oxford, fol., 1682, and Amsterdam, 1700; but the editio optima is that of Paris, in fol., 1726. The following translation of the whole is in general accurate and faithful: 'The genuine Works of St. Cyprian, with his Life, as written by his Deacon Pontius, all done into English from the Oxford edition, and illustrated with notes, by Nathaniel Marshall, LL.B.,' fol., 1717. The whole works and life have also been translated into French, by Lombert, 1682. Translations of separate tracts are very numerous. That *On Mortality*, with others, is Englished by Elyot, 1534; by Brende, 1553; by Story, 1556; and by Lupset, 1560. *On the Lord's Prayer*, by Paynel, 1539. *On Virgins*, by Barksdale, 1675. *On the Unity of the Church*, by Bishop Fell, 4o., 1681; and by Horsburgh, 1815. (Watt's *Bibliothec.*) The life and martyrdom of Cyprian, by Pontius, his intimate friend, is still extant, and printed in several editions of the 'Opera Omnia;' but the style is too rhetorical for simple truth. The substance of this account is given in Lardner's *Credib.*, vol. iii. The *Lives of the Saints*, by the Rev. Alban Butler, (vol. ix., p. 172,) contains an elaborate biography of Cyprian. See also Dr. Adam Clarke's *Succession of Sacred Lit.*, vol. i., p. 177; Cave's *Hist. Lit.*; Le Clerc's *Biblioth.*; Tillemont and Bollandus.

CYPRICA/RDIA. [SUBMYTILACEA.]

CYPRINA. [VENERIDÆ.]

CYPRINIDÆ, a family of fishes, of the section Malacopterygii Abdominales, the species of which are distin-

guished by their having the mouth small, formed by the intermaxillary bones, and generally devoid of teeth; the pharyngeans furnished with strong teeth, the branchiostegous rays few in number, and the scales generally of large size.

The principal genera belonging to this family are—*Cyprinus*, *Barbus*, *Gobio*, *Tinca*, *Cirrhinus*, *Abramis*, *Labeo*, *Catostomus*, *Leuciscus*, *Gonorhynchus*, *Cobitis*, *Anableps*, *Pæcilla*, *Lebias*, *Fundulus*, *Molinesia*, and *Cyprinodon*.

The genus *Cyprinus* (as now restricted) contains the common carp and allied species, which are distinguished from those of the other genera above enumerated, by their having one long dorsal fin, a small mouth devoid of teeth, the scales of large size, and the second rays of the dorsal and anal fins large, bony, and more or less serrated; branchiostegous rays three in number.

The common Carp (*Cyprinus Carpio*, Linn.) was introduced into this country at an early period (probably between the fourteenth and fifteenth centuries), but neither the date nor the country from which it was imported are precisely known. In Jenyns's 'Manual of British Vertebrate Animals' it is said to be originally from the middle of Europe; and since it thrives best in this part, such is probably the case. It now inhabits most parts of Europe, and in some places its growth is much attended to for the purposes of traffic. It frequents lakes, ponds, and rivers; in the last however it avoids those parts where the current is strong, preferring still water.

The food of the carp consists chiefly of vegetable substances, which are masticated by means of the flat teeth which are situated on the pharyngeans; the larvæ of insects and worms however also afford it nutriment. This fish is of an elongate form, and rather thick; the back is considerably elevated, and the greatest depth of the body, which is beneath the commencement of the dorsal fin, measures rather more than one-third of the entire length: the head is large, and the mouth small in proportion; the lips are furnished with two barbules on each side, situated near the corners of the mouth: the dorsal fin commences in a line with the end of the pectorals, and occupies a space nearly equal to one-third of the entire length; the first ray is short and bony; the second is also bony but long, and serrated on the hinder part; the third ray is the longest, and is flexible, as are likewise the remainder of the rays: the anal fin terminates in a line with the dorsal, and, like that, has the two foremost rays bony, and the second serrated. The pectoral fin has its origin immediately behind the free edge of the operculum; the caudal fin is forked, and the longest rays are double the length of those in the centre. The number of fin-rays are—dorsal, 22; pectoral, 17; ventral, 9; anal, 8; and caudal, 19. The lateral line is straight.

The general colour of the upper parts is a rich olive-brown, which is darkest on the head; the under parts are yellowish-white, and the fins are brown; the ventral and anal fins are tinged with red.

As regards the size and weight of the carp, we extract a few lines from Mr. Yarrell's valuable work. 'Though not so rapid in their growth as some fish,' says this author, 'carp have attained three pounds weight by their sixth year, and six pounds weight before their tenth year. The largest I can refer to are thus noticed in Daniel's Rural Sports:—"Mr. Ladbroke, from his park at Gatton, presented Lord Egremont with a brace that weighed thirty-five pounds, as specimens to ascertain whether the Surrey could not vie with the Sussex carp." In 1793, at the fishing of the large piece of water at Stourhead, where a thousand large brace of killing carp were taken, the largest was thirty inches long, upwards of twenty-two broad, and weighed eighteen pounds.

'At Weston Hall, Staffordshire, the seat of the earl of Bradford, the painting of a carp is preserved, which weighed nineteen and a half pounds. This fish was caught in a lake of twenty-six acres, called the White Sitch, the largest of three pieces of water which ornamented this fine estate.'

Carp are in season for the table from October to April.

The *Crucian Carp*, or *Prussian Carp* (*Cyprinus gibelio*, Bloch), is another species of this genus now naturalized in this country, and which is said to have been introduced from Germany.

This species is considerably less than the common carp; its usual weight is about half a pound; it has been known however to weigh upwards of two pounds.

The Crucian carp may at once be distinguished from the common carp by the absence of barbules on the lips. The greatest depth of the body is equal to one-third of the whole length, the tail included; the lateral line descends in a gentle curve from the upper angle of the operculum below the middle of the body, from whence it is straight; the tail is forked; the longest rays are about one-third longer than the shortest rays; the dorsal and anal fins have a strong bony ray, as in the common carp, but these rays are not so deeply serrated. The number of fin-rays are—dorsal, 18; pectoral, 14; ventral, 9; anal, 8; and caudal, 19.

The colour of the upper parts is olive-brown; the belly is almost white; the cheeks and gill-covers are of a brilliant golden-yellow hue; the fins are for the most part of an orange-red colour.

This fish is found in some of the ponds in the neighbourhood of London, and in other parts of England, but is rather local.

The last species which we shall notice is the Gold Carp (*Cyprinus auratus*, Linn.). The gold and silver fish, as it is termed, has been long known in this country: it is a native of China, and, according to Pennant, was first introduced into England in 1691, but was not generally known till 1728. The gold carp is now completely naturalized, both here and in other parts of Europe, where it has been introduced, and breeds freely, especially in ponds in warm and sheltered situations. In many of the streams of Portugal it abounds, whence they are brought over to this country in the trading vessels for sale.

This fish is too well known to require description. It is subject to much variation not only in colour but in the fins, which are sometimes double, and not unfrequently have triple tails; in the latter case however it appears that the tail is thus developed at the expense of part or the whole of some other fin. When young, the gold carp is of a very dark colour, approaching to black; this dark colour is replaced by the golden-red hue more or less early according to the constitution of the individual.

CYPRINUS. [CYPRINIDÆ.]

CYPRIS. [BRANCHIOPODA, vol. v., p. 341 et seq.; CRUSTACEA, vol. viii., p. 198.]

CYPRUS (Κύπρος), called by the Turks Kibris, a large island in the Mediterranean, lying near the coasts of Syria and Asia Minor. Its length is 140 miles, from Cape St. Andrea at the north-east extremity, in 34° 41' E. long., to Cape St. Epiphania, the antient Acamas, at its west end, in 32° 18'. Its greatest breadth, which is in the west part, is about 50 miles from north to south; but it gradually narrows towards the east, being no more than five miles wide at the east end, which is 65 miles distant from Latakiah, the nearest point of the Syrian coast. The nearest point of the coast of Cilicia or Caramania, Cape Zephyrium, is about 42 miles north by west of the point of land in Cyprus which is near the antient Carpasia. A range of mountains runs through the island in the direction of its length, keeping closer to the north than to the south coast: the plains are consequently chiefly on the south side of the range. These mountains, called Olympus by the antients, are now known by several names; the highest summits are the Thrados, 24 miles north of Limasol, which is above 7000 feet; Mount Santa Croce, 18 miles north of Larnika, upon which is a church, said to have been founded by Helena, the mother of Constantine; and Buttavent, five miles from Cerini, near the north coast, with a monastery and an old castle upon it, from which there is a splendid view. (Mariti, *Travels in Cyprus*.) The most extensive plain, called Messarea, is in the south-east part of the island, and is watered by the river Pedæus, which is however nearly dry in summer, like all the other rivers of the island.

Strabo (Casaub. 682, &c.) gives the following enumeration of the towns of Cyprus in his time. On the north coast, east of Cape Acamas, were Arsinoe, Soli, with a harbour, founded by Phalerus and Acamas of Athens; Limenia, inland; then east of Cape Crommyon, Lapathus, built by the Lacedemonians; next Agidus, Aphrodisium, and Carpasia; east of the last was a mountain and cape called Olympus, with a temple of Venus upon it, which women were forbidden to enter. Facing the cape are two small islands, called Cleides, or the keys of Cyprus. (Herod. v. 108.) Turning thence towards the south was Salamis, at the mouth of the Pedæus, one of the principal cities of the island, said to have been built by Teucer, an emigrant from the island of Salamis. Proceeding southwards was

another Arsinoe, with a port; next came Leucolla, near Cape Pedalium, a lofty table-land, called the Table of Venus. West of Pedalium was Citium, with a harbour that could be closed. Citium was a large town, and the birth-place of Zeno the Stoic. From Citium to Berytus in Syria the distance was 1500 stadia. West of Citium was Amathus. Inland was Palæa, and another mountain called Olympus. Sailing round Cape Curias to the west, was the town of Curium, with a port, built by the Argivi. Here the coast turns to the north-west, looking towards Rhodes, and had the towns of Treta, Boosoura, and Old Paphos; then Cape Zephyrium; and next to it another Arsinoe, with a port and temple and sacred grove, and New Paphos, built by Agapenor, 60 stadia by land from Old Paphos. [BAFFO.]

Most of the above towns, and others which Strabo has left out, have long since disappeared. The present towns of Cyprus are, 1. Leikosia, vulgarly called Nikosia, the capital of the island, and the residence of the Turkish governor, which is near the site of the antient Letra, or Leucotra. Its population is said to be above 12,000; it lies in the centre of the island, in a plain surrounded by mountains. Leikosia was the residence of the kings of Cyprus of the Lusignan dynasty, and was then much larger than at present: the Venetians destroyed part of it in order to strengthen the remainder. It is now three miles in circumference. The church of St. Sophia, a fine Gothic building, is converted into a mosque: the monuments of the Lusignans in it are sadly mutilated. There are also a fine bazaar, a khan or enclosed court, surrounded by apartments for travellers, and the palace of the governor, on the portal of which is still seen the Venetian lion in stone; and several other churches and mosques. The archbishop of Leikosia is metropolitan of the whole island. 2. Famagosta, on the south-east coast, a few miles south of old Salamis, and not far from the site of the antient Tamassus, once famous for its copper-mines, is a town strongly fortified by the Venetians, but now much depopulated and decayed. 3. Larnika, on the site of old Citium, near the south coast, is the most thriving bustling place in the island, being the residence of the European consuls and factors, and the seat of the chief trade. The port of Larnika is at Salines, about one mile and a half from it. A Greek bishop resides at Larnika, and there are also some Latin churches in the town. The houses are built chiefly of clay, and only one story high above the ground-floor, on account of the earthquakes to which the island is subject. The interior of the houses however is comfortable, the apartments are paved with white marble, and almost every house has a garden, of which the Cypriotes are very fond. The principal exports consist of cotton, wine, the best of which is produced near Limasol, salt, corn, opium, turpentine, silk, and fruit. A great part of the island is uncultivated, and is covered with thyme and other aromatic herbs. There are quarries of asbestos, talc, red jasper, agate, and rock-crystal. 4. Limisso, or Limasol, near the antient Amathus: the country here is very fertile in vine and other fruit-trees; carob trees are especially abundant. 5. Baffo, or New Paphos, already mentioned. 6. On the north coast is Cerini, the antient Cerinia, with a fort and a small harbour, from which there is some traffic with the opposite coast of Caramania. Besides these, there are a few Greek villages and several monasteries scattered about the island. The majority of the population are of the Greek Church; there are however some of the Latin communion, as well as Maronites, who also belong to the Western Church.

Cyprus appears to have been colonized by the Phœnicians at an early period. Ethiopians are also mentioned as forming part of the population, but it is difficult to say exactly who are designated under this name: probably some of the tribes south of Egypt who were taken to Cyprus as slaves after it came into the possession of the Egyptians. Greek colonies afterwards settled on the coast. According to Strabo it was divided among several petty tyrants, some say nine in number, who were at times at war with and sometimes allied to the neighbouring powers of Asia Minor and Greece. Amasis, king of Egypt, is said to have invaded Cyprus and taken Citium. The island became subject to the Persians (Herod. v. 108); and afterwards submitted to Alexander the Great, upon whose death it fell, with Egypt, to the share of Ptolemy, the son of Lagus. It continued under the Ptolemies, sometimes united with Egypt, and sometimes under a separate prince of the same dynasty. The last of these princes, brother to Ptolemy Auletes, king

of Egypt, incurred the enmity of P. Clodius Pulcher, who, being taken prisoner by the Cilician pirates, sent to the king of Cyprus for money to pay his ransom. The king sent a sum which was too little. Clodius having recovered his liberty by other means, when he became tribune of the people obtained a decree to be passed for reducing Cyprus to a Roman province. (Strabo, 684, and Dion, xxxviii. 30.) M. Cato was sent to take possession of it. The king, on hearing of this design, put himself to death before Cato's arrival. Cato seized upon the treasury, which was well filled, and sent a large booty to Rome. Cyprus thus became a Roman province. On the division of the empire it fell to the lot of the Byzantine emperors, and after several vicissitudes became a separate principality under a branch of the Comneni. Richard of England took it in 1191, and sold it to the Templars, whose oppression drove the people to revolt. Richard resumed the sovereignty, and gave it to Guy of Lusignan, the expelled king of Jerusalem, in 1192. The Lusignans retained it for nearly three centuries, which was a flourishing period for Cyprus. John III. of Lusignan died in 1458, leaving the kingdom to Charlotte, his only legitimate child, who married her cousin Louis, Count of Geneva, second son of the duke of Savoy and of Anna of Cyprus. She was solemnly crowned at Leikosia in 1460, but was soon after expelled by her natural brother James, assisted by the Mamelukes of Egypt. James married Catharine Cornaro, the daughter of a Venetian merchant, who brought him a dowry of 100,000 golden ducats. On this occasion the Venetian senate adopted Catharine Cornaro as daughter of St. Mark, and the marriage was celebrated in 1471. In 1473 James died, and his wife soon after was delivered of a son, of whom the republic of Venice assumed the guardianship, and Venetian troops were sent to garrison the towns of the island. The child dying while an infant, the senate persuaded Catharine, in 1489, to abdicate the sovereignty in favour of the republic, and to retire to Asolo near Treviso, where she lived the rest of her days in a princely style on a liberal pension. Meantime Charlotte Lusignan had retired to Rome, where she died in 1487, bequeathing her claims to Charles Duke of Savoy, in consequence of which the sovereigns of that dynasty assume to this day the title of Kings of Cyprus and Jerusalem. The Venetians kept possession of Cyprus till 1470, when Selim II. sent a powerful force to invade the island. The Turks took Leikosia by storm, and massacred about 20,000 people. They then laid siege to Famagosta, which was long and gallantly defended by the provveditor-general, Marcantonio Bragadino. At last, in August, 1571, the Venetians were obliged to capitulate, on condition of being sent safely home. The pacha Mustapha signed the capitulation, but when Bragadino with the other Venetian officers repaired to his tent to deliver the keys, he had them all seized and put to death, except Bragadino, whom, after some days, he caused to be led naked to the square of Famagosta, where, in the pacha's presence, the executioner began to flay him alive. Bragadino expired in the midst of the torments, which he endured to the last with the greatest constancy. His skin was filled with straw and hung up to the yard-arm of the admiral's vessel, in which Mustapha returned to Constantinople. Venice raised a monument to the memory of Bragadino in the church of San Giovanni e Paolo, and his relatives after a time ransomed his skin, which was placed in the monument. From that time the Turks have remained in possession of Cyprus. A revolt broke out among the inhabitants in 1764, but was put down.

CY'PSELUS. [CORINTH.]

CY'PSELUS. [HIRUNDINIDÆ.]

CYR, ST., a village near Versailles, in France, celebrated for its royal abbey, an institution founded by Louis XIV., at the desire of Madame de Maintenon, for the education of young ladies of noble birth. Previous to the foundation of this establishment, St. Cyr was composed only of some peasants' cottages, with the château of the lord of the village. The institution was for two hundred and fifty young ladies who could show a noble descent of four generations on the father's side: they were received between the ages of seven and twelve years, and maintained, instructed, and furnished with everything till they reached the age of twenty. The girls were instructed by about forty ladies, and waited upon by about the same number of

attendants, denominated 'sœurs converses.' The ladies to whom the instruction of the pupils was confided were subject to a monastic rule, but our authority differs as to whether it was that of St. Benedict (Vaysse de Villiers) or St. Augustin (Prudhomme); the dress of the pupils was plain, without being monastic, and they did not use the monastic style of address, 'mother' and 'sister,' but 'madame,' with the name of the individual spoken to, as usual in society. On quitting the establishment they received a dowry of a thousand crowns. The buildings of the abbey were designed by Jules Hardouin Mansard, the favoured architect of Louis XIV., and consisted of twelve principal piles of building, forming five courts, with extensive gardens attached. The buildings were commenced in 1685 and completed in a year; 2500 workmen were engaged in the work. Louis XIV. was in the habit of visiting Madame de Maintenon in a pavilion in the garden; and in the buildings of the institution the young ladies used to perform the 'Esther' of Racine, whose 'Athalie' was also written for them, though only performed by them twice, and that without dresses, and not in their theatre. Madame de Maintenon passed the close of her life at St. Cyr, and dying there A.D. 1719, was buried in the choir of the church, where a long epitaph, in French and Latin, was inscribed to her praise.

This establishment was suppressed at the Revolution, and the buildings were at first devoted to the purpose of a military hospital, subsidiary to the Hôtel Royal of Paris. In 1814 Napoleon transferred hither the military school of Fontainebleau, and the restored government of the Bourbons sanctioned the change. The gardens have been converted partly into parades for the pupils and partly into a kitchen-garden. The establishment includes a governor of the rank of general, a lieutenant-governor of the rank of colonel, twenty-four professors, and a variety of other officers. The pupils amount to 350, part of whom are maintained by the government and part are at their own charge. They enter between the ages of sixteen and twenty, and about 140 leave the institution every year; some stay two years, and others three. (Dulaure, *Histoire des Environs de Paris*; Prudhomme, *Dictionnaire Universel de la France*. Vaysse de Villiers.)

CYRE'NA. [VENERIDÆ.]

CYRENA'ICA, a region of North Africa, comprehending the country between the Great Syrtis and the Gulf of Platea, now Bomba. The western limits between Cyrenaica and the Carthaginian dominions were fixed at the Philænorum Aræ at the bottom of the Great Syrtis, and its east limits towards Egypt seem to have been about the Catabathmus Magnus. Cyrene, Teuchira, and Hesperis were the earliest Greek colonies. Barca was a colony of Cyrene, mixed with Libyan aborigines. Afterwards, under the Ptolemies, Teuchira took the name of Arsinoe, Hesperis was called Berenice, and the port of Barca became the city of Ptolemais, and drew to it most of the inhabitants of Barca itself. The port of Cyrene, called Apollonia, became also an important town. From these five cities, Cyrene, Apollonia, Ptolemais now Ptolometa, Arsinoe, and Berenice, the country was sometimes called Pentapolis. The interior was peopled by Libyan tribes. There were also other towns mentioned as having existed in this country in the Roman period, such as Darnis, Hadriana, Neapolis, Thintis, &c.; but their site is not well ascertained, except Darnis, which is believed to have been where Derna is now. This interesting region remained for many centuries unexplored by European travellers, until an Italian, Dr. Della Cella, in the service of the pacha of Tripoli, visited it in 1817. 'Viaggio da Tripoli di Barberia alle Frontiere Occidentali dell'Egitto,' Genoa, 1819. The narrative is in a series of letters to a friend, and is written in a simple unpretending style. Dr. Della Cella's observations were made in haste, and without much opportunity for taking an accurate survey of the country. In 1821-2, Captain Beechey, R.N., and H. W. Beechey, explored the coast of the Pentapolis, as well as the ruins of Cyrene: 'Expedition to explore the North Coast of Africa from Tripoli eastward, comprehending an Account of the greater Syrtis and Cyrenaica, and of the antient Cities composing the Pentapolis,' 4to., London, 1828, with maps and plates, a most interesting work. Lastly, this country was visited by M. Pacho, a young and enterprising French traveller, whose melancholy death happened just before the publication of his work: 'Rélacion d'un Voyage dans la Marmarique, la Cy-

rénaique et les Oases d'Audjelah and de Maradeh, accompagnées de Cartes Géographiques et Topographiques et de Planches représentant les Monumens,' 4to., with Atlas, fol., Paris, 1827-9. In describing this country, we shall follow the route of MM. Beechey, who went from Tripoli round by the shores of the Great Syrtis to Bengazi. Pacho, coming from Egypt, entered Cyrenaica on the opposite side by Derna, and his information is most valuable and novel on that part of the country known in antient times by the name of Marmarica, and which extends from Alexandria to Derna. He also visited the great Oases of Augila and Maradeh, which lie in the Libyan desert, south of Cyrenaica.

As the traveller approaches Bengazi from the south he sees the country improve, and leaving behind the sandy tracts of the Syrtis, which continue to spread inland in an eastern direction, he enters a new region of hills and plains fit for cultivation, and covered with vegetation. The coast stretches to the north-east, forming a curvilinear peninsula which advances into the Mediterranean, between the Great Syrtis to the west and the Gulf of Bomba to the east. The chord of this curve from Bengazi to Bomba is about 150 miles, but the sweep of the coast is above 200. A ridge of mountains from 800 to 1100 feet high begins to the south-east of Bengazi, and extends to the north-east in a diagonal direction to the shore, being distant from Bengazi about fourteen miles, from Teuchira five, from Ptolemeta about two, and then comes close to the sea at Ras Sem, continuing along the coast to Apollonia, and as far as Derna. Farther inland is another range, nearly 2000 feet above the sea, which forms the plateau on which Cyrene stood, and which declines gradually towards the east, and blends with the lower one near Cape Bujebara. It then joins the mountains of Akabah el Soloum, the Catathmus Magnus of the antients, which run through Marmarica in a south-east direction to the Oasis of Siwah. To the south and south-west the mountains of Cyrene slope gradually to the level of the Libyan desert and of the sandy tract which borders the Great Syrtis. According to Pacho, the greatest breadth of the hilly region from north to south is between seventy and eighty miles. Towards the north both the higher and lower ridges are frequently broken by deep wadys or chasms, through which the winter torrents rush to the sea. In these chasms or valleys grow a vast number of pine trees, generally small, though some are large enough for top-masts of a man-of-war. The largest of these chasms is near Cape Ras Sem, with a perennial stream running through it, which is supplied from the fountain of Cyrene. Clusters of date trees are seen near Bengazi and Derna. The road from Bengazi to Tocra or Teuchira and Ptolemeta, lies through a very fertile and beautiful country, though a comparatively small part of it is cultivated. It is a plain, thickly covered with wood and flowering shrubs, stretching from the sea to the foot of the mountains, and narrowing every mile as we proceed towards Ptolemeta, where the high land comes very close to the sea. The whole length of the plain from Bengazi to Ptolemeta is fifty-seven geographical miles. The sides of the mountains also are thickly clothed with wood, chiefly pine of various kinds, and numerous shrubs, among which the juniper abounds. Ravines whose sides are covered with wood and verdure cross the road very frequently in their course from the mountains to the sea, most of which must be impassable in the rainy seasons, as there is nothing like a bridge over any of them. Open spaces, some of considerable extent, also occur occasionally in the woods; they were probably once cultivated, but are now thickly covered with grasses of various kinds, among which oats grow spontaneously, as well as a species of wild artichoke, which is eaten raw by the Arabs. Several towers of very solid construction are scattered along this road.

Of the five towns of the Pentapolis, Bengazi is generally believed to occupy the site of the antient Hesperis, afterwards called Berenice, of which there are hardly any remains above ground. [BENGAZI.] In the neighbourhood of Bengazi there are some curious chasms or pits sunk in the rock sixty or seventy feet below the plain, with excellent soil at the bottom, covered with trees and rich vegetation, and which seem to answer to the description of Scylax of the gardens of the Hesperides. The next town on the coast is Tocra, the antient Teuchira, afterwards called Arsinoe, which, although totally deserted, is still completely inclosed, except on the sea or north side, by walls of uncommon solidity and thickness, strengthened at intervals by quadrangular towers, twenty-six in number, and is entered by two

strong-built gateways placed opposite to each other on the east and west sides of the walls. The circuit of Teuchira is about one mile and a half. It is situated in a plain about four miles from the foot of the mountains. The interior of Teuchira has been utterly destroyed, and the few remains, among which are those of a handsome Christian church, are not distinct enough to give an idea of the former buildings. The line of some of the streets however is distinctly traced. We know very little about the history of Teuchira, or of the epoch of its final destruction. The walls were repaired by Justinian, in doing which blocks of stone and marble have been introduced, many of them bearing Greek inscriptions, which evidently formed part of much older buildings. A number of quarries with excavated tombs are seen outside of the city walls. There is no appearance of a port at Teuchira, and the position of the coast is such as not to afford shelter to vessels. Ptolemeta or Dolmeta is also ruined: several of the buildings however are partly standing, such as a lofty gateway, an amphitheatre, two theatres, a palace or large building, the inner court of which retains its tessellated pavement; several columns are still erect, and a number of others are thrown down in heaps. Though the walls of Ptolemeta have been thrown down, their line can be traced in many places, but nowhere do they rise more than one foot above the ground. Ptolemais was originally the port of Barca, which latter is mentioned as one of the five cities of the Pentapolis, though it was inhabited by a mixed Greek and Libyan race. Ptolemais and Barca have been confounded by some geographers, but Ptolemy distinguishes them, and Scylax says that Barca was 100 stadia from the sea. Under the Ptolemies of Egypt, the port of Barca assumed the name of Ptolemais; and in the vicissitudes of the country, the Greek population of Barca withdrew to Ptolemais, which flourished through its maritime trade. Pomponius Mela mentions Ptolemais, and not Barca, among the cities of Pentapolis. Barce or Barca was however still inhabited under the Arabs, who gave its name to the whole country of the Pentapolis; but the town sank at last into total desolation and oblivion, and even its site is not now ascertained, though probabilities are for its being in the plain of Merdje on the first ridge of hills south of Ptolemeta, and on the road to Cyrene. (BARCA; and also Beechey's *Narrative* and *Quotations*.) Ptolemeta lies in a delightful position at the foot of the hills, and on a slope stretching to the sea between two romantic wadys or ravines. Its extent, as far as it can be traced, was about one square mile: but the whole space is now overgrown with wild vegetation, with patches of corn here and there among the ruins. The Arabs sow the corn and leave it to the winter rains, and they return at harvest time to cut and carry it off. There are several large cisterns in good preservation, which were restored by Justinian, and now afford a supply of good water.

The road from Ptolemeta to Cyrene leads up a romantic valley, the sides of which are thickly clothed with pines, olive trees, and various kinds of laurel, interspersed with clusters of luxuriant honeysuckles, myrtle, arbutus, juniper, and a variety of wild roses, and then opens into the plain of Merdje, a large and fertile tract about five miles in breadth, on the summit of the first range of mountains, with pools and small lakes formed by the waters from the upper ridge. The Arabs encamp here, and partly sow the ground with corn, and use the rest as pastures. From the plain of Merdje the path follows the track of the antient road in a north-east direction leading through a succession of hills and fine vallies to Ghrenna, the Arab name for Cyrene. On approaching Ghrenna the country becomes more clear of wood, the valleys produce fine crops of barley, and the hills afford excellent pasture for cattle. A plant, three feet high, perhaps the silphium of the antients, and resembling in shape the hemlock, grows here in great abundance. The position of Cyrene is one of the finest that can be imagined, being on the edge of the upper range of hills about 800 feet above the lower range. Below the town the hill slopes down towards the north, forming several natural terraces one below the other, and terminating with a fine sweep of table-land, which forms the summit of the lower range, and which is covered with wood, with scattered tracts of corn and verdant pastures. Ravines whose sides are overgrown with trees, intersect the country in various directions, and form the channels of mountain streams. This table-land extends east and west

as far as the eye can reach, and to the north after stretching about five miles, it descends abruptly to the sea. The slope of the lower ridge, which runs along the coast of Cyrenaica, is here thickly covered with wood. Its height is about 1000 feet, so that Cyrene is about 1800 feet above the sea, of which it commands an extensive view. The ledges or terraces of the upper ridge afforded room for roads or drives sweeping along the sides of the mountain, and the tracks of the chariot wheels are still impressed upon the rock. The remains of Cyrene occupy a vast extent of ground, but they have been sadly disfigured by the hand of man. Innumerable tombs, either built of stone or excavated in the rock, encircle the town, and are ranged on each side of the avenues leading to it. In some of these excavations paintings have been found in good preservation, representing funeral games, hunting parties, several sketches of private life, and allegorical subjects. The costumes are beautifully rendered, and the colours very brilliant. Within the precincts of the antient town are the remains of a bath built of brick, of which some parts of the vaulted work are still left, some towers or forts, a very large hypogeum picturesquely situated on the extremity of the only grove that is found on the plateau, several large temples of the Doric order, two small excavated temples of the Roman period with Christian emblems, two theatres, an amphitheatre, an aqueduct, but all sadly damaged; in fact, the whole of the existing remains are at present little more than one mass of ruins, and the tombs afford the most perfect examples of Grecian art now remaining in Cyrene. A quantity of prostrate columns, statues, capitals, reliefs, and inscriptions, are scattered about the ground, but the statues are mutilated, and many of them want their heads, which the Arabs have cut off. There are two copious springs, from one of which, supposed to be the fountain of Apollo, the water flows into a subterranean channel, and then issues out on the other side of the mountain.

The country around Cyrene must have been in the time of its splendour a complete garden, and it is easy to conceive how the people of such a country became so much addicted to luxury and pleasure as they are reported to have been. Even now in its wild state 'the rich ochrish red soil, watered by rivulets gushing on every side, brings forth a rich vegetation which pierces the mossy rocks, clothes the hills, extends in rich pastures, or develops itself in forests of dark juniper, green thaya, and pale olive trees. The modern name of the Cyrenaica, "Jebel Akhdar," i. e., "the green mountain," expressively indicates its rich and smiling aspect.' (Pacho, *Voyages dans la Marmarique et la Cyrénaïque*.)

Cyrene appears to have gradually declined under the Romans as the maritime towns of the Pentapolis rose in importance. It afterwards suffered greatly, and was in a great measure ruined during the dreadful insurrections of the Jews under the reigns of Trajan and Hadrian; the province was depopulated when Hadrian colonized it afresh, at which time it is probable that many of the buildings of Cyrene were restored, for there is a variety of Greek and Roman style observable in them as well as in the sculptures. The Jews were at one time very numerous in Cyrenaica; they had settled in it in the time of the Ptolemies, and chiefly resided at Berenice, where they formed a distinct community governed by two archons.

In the fourth century, Synesius, bishop of Ptolemais, one of the most eloquent of the early fathers, deplored the ruin and depopulation of Cyrene, hastened by the oppressions of the Byzantine governors. It was in his time that Cyrene was destroyed by an invasion of some barbarous hordes of the interior of Libya, whose women were armed as well as the men, who destroyed all before them, and only spared the male children to recruit their ranks. (Synesii *Opera*, p. 300.) Those of the inhabitants of Cyrene who escaped took refuge at Ptolemais. The barbarians besieged Ptolemais, in which Synesius had remained faithful to his flock, and they were repulsed. In the early part of the seventh century the Persians under Khosroo Purveez, after overrunning Egypt, invaded the Pentapolis and depopulated the country. The Saracens afterwards completed the work of the Persians, and the towns of the Pentapolis have remained in ruins ever since. Now the nomade Arabs wander about the whole region, which is nominally subject to the Beys of Bengazi and of Derna, who are dependants of the pacha of Tripoli. Apollonia, afterwards Sozysa, and now called Mersa Soosa, was the port of Cyrene, from which it

is about twelve miles distant. The antient road leading to it still remains. Apollonia lies at the bottom of an open bay, protected however by two small islands in front of the town. The town is ruined, but the greater part of the wall is standing, and there are remains of two Christian churches, the columns of which are of fine marble, of a basilica, a fort, &c. MM. Beecheys have given plans of Ptolemeta, Teuchira, Apollonia, and Cyrene, as well as of the modern towns of Bengazi and Derna. Pacho's Atlas gives many views and plans of the different monuments of Cyrene, Ptolemeta, &c.

CYRENAICS, a school of philosophers among the Greeks, who derived their name from the birth-place of their founder Aristippus. Like the Cynics, their doctrines were a partial development of those of Socrates; but the view which they took of their predecessor's philosophy was quite different from the Cynical. [CYNICS.] The only particular in which the two sects agreed with the original system and with one another was that they all three made virtue consist in knowledge; in other words they were all three attempts to awaken and develop the idea of science; but while the Cynics considered all sublunary enjoyment and most branches of knowledge as impediments to the knowledge, and consequently, according to Socrates, to the practice, of virtue, the Cyrenaics, on the other hand, were not contented with the mere knowledge of the good as a general term, but sought for it in the separate particulars, and deemed him to have performed his proper functions most consistently with his nature who had succeeded in amassing the greatest number of particular good things. In regard to the idea of science, they did not look upon it as a speculative conception, but as a merely empirical result, as the aggregation of successive experiences; in other words, not as an intuition but as a combination of perceptions; and while Plato, and in some measure the Cynics also, placed the *summum bonum* in the attainment, by means of dialectics, of the abstract idea of the good, the Cyrenaics placed it in the collection of the greatest number of agreeable perceptions, and the true philosopher, according to them, was one who actively, methodically, and successfully carried on the pursuit of pleasure. Consequently, as agreeable perceptions; were continually to be sought as good and the contrary to be avoided as bad in themselves, perception of sensible objects became the criterion of all knowledge and the object of all action, and therefore truth both theoretical and practical. (Sextus Empir. *adv. Mathematicos*, vii., § 191—200.) The chief successors of Aristippus were Theodorus, Hegesias, and Anniceris. Theodorus perceived the necessity for some principle, in addition to the mere collection of agreeable sensations; for without some effort of the understanding to determine which of many gratifications was to be preferred, it would be impossible, he thought, to obtain the maximum of gratification; and he therefore set the understanding over the senses as a regulating and restraining faculty. He is said to have been banished from Athens for denying the existence of the gods. (Diog. Laërt., ii., § 97.) Hegesias, following in the steps of Theodorus, insisted still more than he did upon the inadequacy of the senses as the criteria of the desirable, and at last even went so far as to assert that nothing was in itself either agreeable or the contrary, and that life and everything in life should be a matter of indifference to the wise man. In this assertion of the principle of indifference he made an approach to the doctrines of Epicurus and the Stoics in the point in which those two opposite systems met. Cicero tells us (*Tuscul. Disput.*, i., c. 34) that his book called *ἀποκατεργῶν* caused so many suicides that he was forbidden by one of the Ptolemies to lecture on the worthlessness of life. In the philosophy of Anniceris and his followers the original principles of the Cyrenaics were quite lost, and though he also, in a popular way, recommended the pursuit of the agreeable, he denied that it depended in any way upon mere sensible impressions, for that the wise man might be happy in spite of all annoyances; that friendship was to be sought, not for the sake of any immediate advantage to be derived from it, but on account of the good-will which it generated; and that for a friend's sake a man should encounter even annoyances and troubles. (Diog. Laërt. ii., § 96, 97.) These are the doctrines of a mere popular morality, and can hardly be ascribed to one school more than to any other. It will be remarked by every one that the original tenets of this school were very similar to those of Epicurus; indeed, with the exception of the atomic sys-

tem which he borrowed from Democritus and Leucippus, the two systems differed only in this: the Cyrenaics placed the great object of man in the positive and active pursuit of the agreeable, while Epicurus made it consist in a perfect rest of mind and in freedom from pain; for he considered the agreeable as something merely negative, as the pleasing harmony produced by exemption from all passion and appetite. The philosophy of Epicurus may therefore be considered as the successor, in one point of view, of the system of Aristippus.

CYRENE (*Κυρήνη*), a city of Libya, near the coast, to the east of the Great Syrtis, was founded B. C. 631, by a colony from Thera (Herod. iv. 155), an island in the Ægean sea. Thera was a Lacedæmonian colony (Herod. iv. 148), and when Isocrates (Philip. § 254) speaks of the people of Cyrene as a colony from Lacedæmon, it is either on account of the origin of Thera itself, or because, as is reported by Pausanias (iii. 14), Anchionis and a considerable number of Lacedæmonians accompanied Battus, the leader of the colony, to the coast of Libya. Battus, according to Herodotus (iv. 155), was the son of Polymnestus, one of the principal citizens of Thera, and received this surname on account of an impediment in his speech; Callimachus, who appears to have been one of his descendants (Strabo, pp. 837, 838, *b. a.*) gives (*Hymn to Apollo*, v. 76) Aristoteles as the original name of Battus, and this is confirmed by the Scholiast on Pindar (*Pyth.* iv. 104). The immediate occasion on which the colony was planted is variously stated by different writers: it was probably the result of some political commotion in which the vanquished party was forced to quit the island. At any rate it appears that the Delphic oracle was consulted, and that its suggestion was taken. Battus and his comrades sailed for the coast of Libya, but they had not proceeded far before they were alarmed at the dangers of the navigation, and resolved to put back to Thera. On approaching the island they were pelted by the inhabitants on the shore, and being unable to land, they had no alternative but to set sail again. They at last reached the coast of Libya and settled in an island called Platea, where they remained two years; afterwards they removed to Aziris, where they remained six years, and at length settled in the place which they called Cyrene, a name said to be derived from a fountain Cyre flowing near. The following is a list of the kings of Cyrene, with the length of their reigns, as far as can be ascertained:—

Battus I. (reigned 40 years), died about B. C. 591; Arcesilaus I. (16 years), B. C. 575; Battus II., surnamed the Happy (21 years), B. C. 554; in this reign the colony was greatly increased by emigrants from Greece; Arcesilaus II. (4 years), put to death B. C. 550; Battus III., surnamed the Lamé (about 21 years), B. C. 529; in this reign, Demonax, of Mantinea, introduced laws which greatly modified the constitution and diminished the royal power; Arcesilaus III. (about 13 years), B. C. 516; this king submitted to the Persians (Herod. iii. 13), but afterwards recovered the kingship and exercised his power so tyrannically that he was assassinated in Barca. Of Battus IV. and Arcesilaus IV. we have no certain information. About B. C. 450 the government appears to have changed to a republic, but the particulars of the constitution are unknown. (Aristoteles, *Politic.* vi. 4). The subsequent history of Cyrene seems to have been a series of changes and internal troubles till after the time of Alexander, when it became subject to Egypt in the reign of the first Ptolemy, and so it continued till Ptolemy Physcon, whose bastard son Apion, being in possession of the chief power, gave it into the hands of the Romans about B. C. 97. Strabo says (837 *c.*) that in his time the kingdom of Cyrene, with Crete, formed a Roman province.

[Coin of Cyrene.]

British Museum. Actual Size. Gold. Weight, 68 grains.

Cyrene produced many celebrated persons: Aristippus, his daughter Areta, and her son Aristippus, Anniceris, Eratosthenes, and Carneades, besides Callimachus, the poet. Aristippus the Elder was the founder of that sect of So-

cratic philosophers which was called Cyrenaic, from his birthplace. (Strabo, pp. 837 *d.* 838 *a.*)

Cyrene was famous for a fine breed of horses. The Cyrenæan doctors had a high reputation; they were considered in Greece at one time to be inferior only to the doctors of Croton (Herod. iii. 131). (Herodotus, iv. 154-167; Strabo, pp. 56 *d.*, 836, 837, 838).

CYRIL, ST., of Jerusalem, was born in that city about A. D. 315; and received among the clergy there an education for the church. In 345 he was ordained priest and catechist by Maximus, the Patriarch, or, which in fact is the same thing, archbishop of Jerusalem. On the death of that prelate, A. D. 350, Cyril was chosen to succeed him, and the commencement of his episcopate is said to have been signalized by a wonderful luminous appearance in the heavens, called the Apparition of the Cross. It is spoken of in the Chronicle of Alexandria, by Socrates (lib. ii. c. 28), by Philostorgius (lib. iii. c. 26), and by several other ecclesiastical historians. The letter immediately written by St. Cyril to the emperor Constantius describing this miraculous phenomenon, is quoted in proof of the fact by Sozomen, Glycas, Theophanes, John of Nicæa, Eutychius, and many subsequent writers. Dr. Cave, in his *Life of St. Cyril*, inserts it entire. It is stated that on the nones (7th) of May, A. D. 351, at nine in the morning, a great mass of light, far brighter than the sun, was observed over Golgotha, and extending to Mount Olivet (two English miles); that it assumed the form of a cross, and was seen during several hours by all the inhabitants of Jerusalem. The expression of a wish, with which the letter of Cyril concludes, that Constantius might glorify the consubstantial Trinity (*τὴν ὁμοούσιον τριάδα*) tends to invalidate the evidence of the fact as an especial miracle, since it shows that Cyril, a zealous Trinitarian controversialist, sought to influence the creed of the emperor, which strongly favoured the Arian tenets: and it is well known to have been a general maxim among the primitive fathers that a pious and orthodox end fully justifies a recourse to any means, however inconsistent with veracity. The zeal with which St. Cyril enforced and defended the doctrine of the consubstantiality of the Son, with the jealousy about precedence, and the ambitious encroachment of jurisdiction, which characterize the episcopal history of that age, occasioned Acacius, the Arian bishop of Cæsarea, to commence a course of persecution against him which terminated in his deposition by a council, A. D. 357. On this he retired to Tarsus until 359, when, by a council of Seleucia, he was re-established in his see, but, through the party of Acacius, he was immediately deposed a second time by a council of Constantinople A. D. 360. On the accession of Julian, who, to increase the broils of the church, recalled all the exiled bishops, Cyril returned to his bishopric, from which, under the emperor Valens, he was expelled a third time by Eudoxus, the Arian bishop of Constantinople, A. D. 367. Finally, under Theodosius, who favoured the Trinitarian sect, he was again restored by a council of Constantinople in 381; and notwithstanding the ambitious and schismatic contests of the bishops and clergy, he remained in his see until his death, A. D. 386. An incident noticed by all the biographers of St. Cyril, is the celebrated attempt of the emperor Julian to rebuild the temple of the Jews at Jerusalem, ostensibly for the purpose of promoting their religion, but really with the sinister view of falsifying the prophecies respecting its irreparable destruction. It is said that notwithstanding the enthusiastic expectations of the Jews, and the prodigious preparations and actual commencement of the work, St. Cyril's reliance on the infallibility of the scriptures induced him to persevere in predicting the failure of the project; and that, accordingly, a series of earthquakes, storms of lightning, and subterraneous eruptions of fire and smoke, destroyed all the materials and a multitude of workmen, the garments of those who escaped being impressed with shining phosphoric crosses, which, even by washing, could not be effaced. The particulars of this miraculous fulfilment of Cyril's prediction are related by St. Gregory Nazian. (*Orat.* 4 *advers. Julian*); by Theodoret, Socrates, St. Chrysostom, Philostorgius, Sozomen, and St. Ambrose. See also bishop Warburton's *Dissert.* on the subject, p. 88.

The extant writings of St. Cyril are in the Greek language, and consist of eighteen books of catecheses, or sermons, delivered during Lent to the catechumens, called before baptism *Illuminati* (*φωτιζόμενοι*): five similar discourses de-

livered during Easter week to the neophytes, after baptism called mystagogic (*μυσταγωγικά*), being explanatory of the mysteries of the Christian sacraments: a treatise on words, and the letter to Constantius: besides which, several homilies and epistles are sometimes improperly included. Rivetus, in his 'Criticus Sacer' (lib. iii. c. 8, 9, 10, de Cyrilli Catechesibus), considers the five Mystagogics, and letter to Constantius, as supposititious, but by Vossius, Cave, Mill, Whittaker, and bishop Bull, they are acknowledged as genuine. The books of Catecheses are crowded with quotations from scripture, and the style is dull and tiresomely prolix; but the facts they contain relating to the doctrines and discipline of the Eastern church in the fourth century are extremely interesting to the student of Christian antiquities. In the first Catechesis are described the effects of baptism. The fourth gives an exposition of all the Christian doctrines, and treats of numerous questions concerning the body, soul, virginity, marriage, &c. The subsequent discourses exhibit and enjoin a belief in the miraculous virtues of the relics of saints, which are represented as worthy of all veneration; in the efficacy of prayers and sacrifices for the dead; in the powers of exorcism, consecrated unction, oil, and water. Christians are exhorted to cross themselves on every occasion and action throughout the day. The enthusiastic adoration of the cross displayed by St. Cyril was probably owing to his officiating in the church of the Holy Cross, in Jerusalem, where, after 'the Invention of the Cross,' it was deposited in a silver case, and shown by the archbishop to thousands of pilgrims, who each took a little chip of it, without occasioning any diminution of its bulk; hence one of his proofs of the truth of the gospel history of the Crucifixion is the fact of the world being full of chips of the cross. A description of this cross is given by Dom Touttée, at the end of his edition of Cyril's works.

The doctrine of the uninterrupted and perpetual virginity of Mary is taught by Cyril. The state of virginity in general is extolled as equal to that of angels; with an assurance that, in the day of judgment, the noblest crowns will be carried off by the virgins. The resurrection is proved and illustrated by the story of the Phoenix, and it is remarkable that this fiction is regarded as a reality not only by St. Cyril, St. Clement, and other Christian bishops, but by many of the most learned and philosophic Gentiles. That Cyril's superstitious credulity and love of the marvellous was remarkably great, is very apparent: for instance, in describing the Descent into Hell, he declares that the doorkeepers of that place, on seeing Jesus, all ran away in a fright; and in his sixth Catechesis on Heresies, he says that Simon Magus, having, by the power of his magic, mounted up into the air in a fiery chariot drawn by a pair of dragons, St. Peter and St. Paul, by their prayers, dissolved the enchantment, and Simon consequently fell to the ground and broke his bones. In the five Mystagogics are described the ceremonies which precede baptism; the anointing with oil the forehead, face, ears, and nose; the forms of exorcism, the holy chrism, confirmation, the eucharist, liturgy, and communion. The dogma of transubstantiation is most explicitly enforced: we are said to be made consubstantial and consanguineal with Christ, by his body and blood being distributed through our bodies. Very minute directions are given for the mode of receiving the eucharistic bread and wine: thus, put your left hand under your right elbow, making with your hollowed right hand a throne for the reception of the body of Christ, and closing your fingers lest a crumb be lost, which would be a greater misfortune than the loss of a limb, &c., then, having drunk of the cup of the blood, moisten the tip of your finger from your lips, and by touching, consecrate your eyes, ears, nose, &c.

For a list of editions of Cyril see Watt's *Biblioth. Brit.*; Mille's ed. of the *Opera Omnia*, Græce et Latine, fol., 1703, contains notes, three indices, and the various readings; but the editio optima is that by Augustus Touttée, a Maurist monk; Gr. et Lat. fol., 1720; (*Lives of Saints*, by the Rev. Alban Butler, vol. iii.; Dr. Adam Clarke's *Succession Sac. Lit.*, vol. i.; Lardner, vol. iv.; Grodecus, *Vita St. Cyrilli*; *Lives of Saints*, vol. i. 4to. 1729.)

CYRIL, ST. (CYRILLUS), of Alexandria, was educated under his uncle Theophilus, the contentious bishop of Alexandria, by whom St. Chrysostom was persecuted and deposed. On the death of Theophilus, A.D. 412, Cyril was so successful in the struggle which, on such occasions, always occurred at that time among the aspiring clergy,

that in three days after his uncle's decease he was elected patriarch, that is archbishop of Alexandria. His episcopal power was first displayed in shutting up and plundering the churches of the puritan sect founded by Novatian, who is said to have been consecrated a bishop by three episcopal friends whom he invited and made drunk for the purpose. (Pluquet, *Dict. des Heres.*) Cyril next exhibited his zeal against heretics by heading a furious mob of fanatics, who drove out all the numerous Jewish population from Alexandria, where, since the time of Alexander, its founder, they had enjoyed many privileges, and were politically important as contributors to the public revenue. This arrogant proceeding therefore highly excited the anger of Orestes, the governor of the city, and made him henceforth the implacable opponent of the bishop, who, in the name of the Holy Trinity and Gospels, in vain implored a reconciliation. In consequence of the enmity thus created, and of Cyril's resentment of the checks opposed to his ambitious encroachments on the jurisdiction of the civil power, a murderous attack was made on the governor in his chariot by a band of 500 monks; and one who severely wounded him having suffered death on the rack, Cyril, in his church, pronounced a pompous eulogy over his body as that of a glorious martyr. (Soc., l. vii., c. 14.) By the philosopher Eunapius (*Vita Aedesii*) these monks are described as swine in human form. The tragic story of Hypatia, the daughter of the mathematician Theon of Alexandria, furnishes further evidence of the revengeful disposition of St. Cyril. This lady, whose wonderful abilities enabled her to preside over the Alexandrine school of Platonic philosophy, was the especial object of the bishop's envy and malice; not only because she far excelled him in the depth and extent of her knowledge, which drew to her lectures the greatest philosophers and statesmen, and a crowd of students from Greece and Asia; but because, from her intimacy with the governor and the great respect and admiration he manifested towards her, Cyril and his clergy suspected her influence in promoting the governor's unfavourable opinion of them. The consequent murder of Hypatia is circumstantially related by several ecclesiastical historians. (Socrates, l. vii., c. 13 and 15; Nicephorus, l. xiv., c. 16; Damascius, in *Vita Isidori*; Hesychius and Suidas, in *Ἑπάρια*; Photius, *Annot. ad Socrat.*, l. vii., c. 15.) In these accounts it is stated that Cyril having vowed the destruction of this accomplished woman, a party of infuriated wretches, whom Nicephorus (*ubi supra*) expressly declares to have been Cyril's clergy, led on by Peter, a preacher, seized her in the street, and having dragged her into a church, completely stripped her, tore her to pieces, carried the mangled fragments of her body through the streets, and finally burnt them to ashes, A.D. 415. (See Toland's *Hypatia, or the History of a most beautiful, virtuous, learned, and accomplished Lady, who was torn to pieces by the Clergy of Alexandria, to gratify the cruelty of their Archbishop, undeservedly styled St. Cyril*, 8vo., 1730.)

The titles of 'Doctor of the Incarnation' and 'Champion of the Virgin' have been given to this bishop on account of his long and tumultuous dispute with Nestorius, bishop of Constantinople, who denied the mystery of the hypostatic union, and contended that the Divinity cannot be born of a woman—that the divine nature was not incarnate in, but only attendant on, Jesus as a man, and therefore that Mary was not entitled to the appellation then commonly used of 'Mother of God.' (Pluquet.) The condemnation and deposition of Nestorius having been decreed by Pope Celestine, Cyril was appointed his vicegerent to execute the sentence, for which he assembled and presided at a council of 60 bishops at Ephesus. But John, the patriarch of Antioch, having, a few days afterwards, held a council of 41 bishops, who supported Nestorius and excommunicated Cyril, the two parties appealed to the Emperor Theodosius, who forthwith committed both Cyril and Nestorius to prison, where they remained for some time under rigorous treatment. Cyril, by the influence of Celestine, was at length liberated and restored, A.D. 431, to the see of Alexandria, which he retained until his death, A.D. 444.

His works are numerous, and chiefly on subjects connected with the Arian controversy, the incarnation, consubstantiality of the Son, and similar difficult points, which are involved in additional obscurity by an intricate perplexity of style and the use of barbarous Greek. The following are some of the principal treatises:—'Thesaurus on the Trinity,' intended as a complete refutation of Arianism. In 'Dialogues on the Incarnation,' in 'Five books

against Nestorius,' and in an ample 'Commentary on St. John's Gospel,' the same subject is continued. Ten books against Julian contain replies to that emperor's three books against the Gospels, which, if Cyril's quotations are faithful, were as weak and absurd as the answers. Seventeen books 'On Worship in Spirit and Truth,' show that all the Mosaical institutions were an allegory of the Gospel; 'a proof,' says Dr. Adam Clarke, 'how Scripture may be tortured to say *any* thing.' Thirteen books on the Pentateuch and the Prophets are written with a similar view. Thirty paschal Homilies, announcing, as customary at Alexandria, the time of Easter, are 'dull, dry, barren, and perfectly uninteresting.' (Dr. A. Clarke.) Sixty-one Epistles nearly all relate to the Nestorian controversy. Cyril's Synodical Letter contains 12 solemn curses against Nestorius, who as solemnly replied with 12 curses against Cyril. In a treatise against the Anthropomorphites, or those Egyptian monks who taught that as man is made in the express image of his Maker, God has the form and substance of a human body, Cyril reproves them for their gluttony and idleness, and answers with great metaphysical skill a series of very perplexing queries, such as whether God can cause what *has* happened, *not* to have happened; whether he can cause a prostitute to have been always a virgin; how angels who are spirits had carnal knowledge of women, &c. Cyril throughout his works enforces the adoration of Mary as the mother of God, and explicitly teaches the doctrine of transubstantiation, declaring that by taking the Lord's body we become consubstantial with God, being blended together like two portions of melted wax. 'The history of none among the Christian fathers,' says Dr. Adam Clarke, 'is more disgraceful to the Christian character than that of St. Cyril, of Alexandria—a man immoderately ambitious, violent, and headstrong; a breeder of disturbances; haughty, imperious, and as unfit for a bishop as a violent, bigoted, unskilful theologian could possibly be—but resolved that if the meek inherit the earth, the violent should have possession of the sees.' The editio optima of the 'Opera Omnia' of Cyril is that in 7 tom. fol., Greek and Lat., Paris, 1638. Spanheim's edition of Julian's works contains Cyril's work against Julian. (Clarke's *Succession Sac. Lit.*, vol. ii., p. 137; Socrates, *ubi supra*; Tillemont, tom. xiv., p. 272; Butler, *Lives of Saints*; Ceillier, tom. xiii., p. 241; Rivetus, *Critic. Sac.*)

CYRILLUS, the author of a Greek Glossary, which some have attributed to the bishop of the same name. It is printed in the appendix to the London edition of H. Stephen's Greek Lexicon, 1826.

CYRTANDRA'CEÆ, a small natural order of irregular-flowered monopetalous Exogens, scarcely distinct from Bignoniaceæ by any positive characters, although they have a very peculiar habit. They are herbaceous plants, and in many cases stemless, with no tendency to twine; sometimes they are parasitical; their calyx, corolla, and stamens are those of Bignoniaceæ, but their fruit is a long slender pod,

[*Streptocarpus Rexii*.]

1, a section across the ripe pod, showing the double placentæ,

containing a multitude of seeds, that are often terminated by long delicate tails, and are destitute of albumen. The pod is two-celled, and each cell has its placentæ doubled back from the axis so as to form two plates at right angles with the dissepiment. The species inhabit the East Indies chiefly, a few only being met with in other warm parts of the world. They are all beautiful in their flowers, but they are of no known use.

CYRUS I. (Κῦρος), founder of the Persian monarchy, began to reign about B.C. 559. Even in the time of Herodotus the history of Cyrus was so obscured by legendary tales that the truth could not be separated from the fiction. His original name appears to have been Agradatos (Strabo, p. 729 d.): the word Cyrus is said to have signified the sun, and this name was probably assumed by him when he became king. (Heeren, *Ideen*.) Cyrus was the son of Cambyses, a Persian, and Mandane, daughter of Astyages, king of Media, and hence was called by the oracle a mule. (Herod. i. 91.) In consequence of Astyages dreaming a dream which portended that the offspring of his daughter would take the throne of the Medes, he ordered Cyrus to be destroyed as soon as he was born. Harpagus, a person of rank in the king's household, was charged with the commission, but being reluctant to execute it, he gave the child to the king's herdsman to put to death. The herdsman's wife, who just at this time was delivered of a still-born male child, persuaded her husband to preserve the life of the royal infant, and their own dead child was accordingly exposed instead of Cyrus, whom they brought up under their own roof. Among his boyish playmates Cyrus exhibited all the royal symptoms of an inclination to command and be obeyed. In their games the youths made him king, and the severity with which he enforced his orders on one of these occasions led to his being brought before Astyages, who recognized in his features a likeness to himself, and found that the time of the exposure of his grandson and the age of Cyrus agreed. The circumstances of his preservation were disclosed, and he was sent to his real parents. Astyages was less enraged against the herdsman than against Harpagus, on whom he wreaked his vengeance by the murder of his son: the youth's mangled limbs were dressed and served up at supper when Harpagus was present, and the head, hands, and feet were afterwards shown to the father in a basket, with insulting expressions. Harpagus said nothing, but meditated revenge; and it was not long before he succeeded in rousing Cyrus against Astyages. Cyrus induced the Persians to revolt against the Medes, and dethroned Astyages B.C. 560. He next attacked and took Sardis, and made Cræsus prisoner B.C. 546. [CRÆSUS.] He besieged and took the city of Babylon B.C. 538, which he entered by diverting the course of the Euphrates and leading his army into the city by the dry bed of the river (i. 190, 191). At last he carried his arms against the Massagetæ, and was defeated and slain by Tomyris, their queen (B.C. 529), who had his head cut off and put into a leathern bag full of human blood, saying, 'Though I am alive and have conquered you, you have undone me by taking my son; but I will, as I threatened, satiate you with blood.' He had reigned twenty-nine years (i. 214). This is the account given by Herodotus, which, with a few variations, is copied by Justin. Xenophon's work on the education of Cyrus is rather an historical romance than a history, and therefore his narrative is less to be depended on than that of Herodotus, from which it differs materially. Both Xenophon and Ctesias (*Persica*, c. 8) [CTESIAS], make Cyrus die quietly a natural death. (See the last chapter of Cicero *De Senectute*.) The account of Ctesias as to his death is conformable with the story in Arrian (*Anab.* vi. 29) of the body of Cyrus being interred at Pasargadæ. [ALEXANDER III., p. 301.] The fame of Cyrus appears to have lasted to the downfall of the Persian empire; he was regarded by his countrymen as their great national hero; and his fame is still preserved in the annals of modern Persia. The Persians gave him the title of father (iii. 89), while they called his son, Cambyses, a tyrant. The capture of Babylon by Cyrus is the point at which sacred history first touches on profane. (Clinton, *Fast. Hel.* p. 301.) Cyrus left two sons, Cambyses, who succeeded him on the throne, and Smerdis, who was murdered by the command of Cambyses. (Herod. iii. 30.)

CYRUS II. was the son of Darius II. and Parysatis. Artaxerxes, the eldest son of Darius, succeeded him as king: but Cyrus disputed the right of succession, and founded his own claim on the fact that he was the first-

born after the accession of his father. Cyrus was the favourite of his mother, Parysatis, and was indebted to her intercession with Artaxerxes for the preservation of his life after he had been charged with a conspiracy against the king. He was sent back to his government in the western provinces of Asia Minor, but did not relinquish his designs on Artaxerxes. Indignant at the disgrace he had suffered by being sentenced to death, he resolved, if possible, to dethrone his brother. The great difficulty was to raise a sufficient force without exciting his brother's suspicions. Clearchus, a Lacedæmonian general, undertook to raise a body of Greek troops for the purpose of making war on some Thracian tribes. Aristippus in Thessalia, and Proxenus in Bœotia, raised troops for similar purposes and with a similar object. Artaxerxes had originally been apprized of the designs of Cyrus by Tissaphernes, but the cities which were in the government of Tissaphernes now all revolted to Cyrus, with the exception of Miletus. A war thus arising between Tissaphernes and Cyrus, gave Cyrus a pretext for openly collecting his forces, and even for soliciting the aid of the king, to whom he made heavy complaints of the conduct of Tissaphernes. Artaxerxes was thus blinded to the real aims of Cyrus, who explained his intentions to no Greek but Clearchus, lest they should be deterred from joining him by the boldness of the attempt. When his forces were all collected, he set out from Sardis, the seat of the Persian authority in Western Asia (B. C. 401), without the soldiers knowing any thing more of the objects of the expedition than that he was going to march against the Pisidians, who had infested his province. Tissaphernes however, with his characteristic cunning, saw that the preparations were much too great to be really intended against the Pisidians, and accordingly he went with all expedition to inform the king. Artaxerxes no sooner heard of the armament of Cyrus than he began to make preparations for opposing him. Cyrus in the mean time was continuing his march through the southern provinces of Asia Minor, passing through Celænæ, Peltæ, Thymbrium, Tyræum, Iconium, and Dana, till he arrived at the foot of the Taurus, which he crossed and arrived at Tarsus. Here the Greeks refused to march any farther: they suspected that they were going against the king, and declared that they were hired for no such purpose. The tumult was partially appeased by the influence of Clearchus, who persuaded them to send deputies to Cyrus to inquire what was the real object of the expedition. Cyrus, by an artful evasion, which however was partly seen through by the soldiers, pretended that he had an enemy, Abrocomas, on the banks of the Euphrates, at the distance of a few days' march, and that he was advancing against him. A promise of half as much pay again as they had received before, induced them to proceed; but it was not till some time after that it was openly stated that they were going against the king. At last, on arriving at the plain of Cynaxa, in the province of Babylon, Cyrus found Artaxerxes ready to oppose him with an immense army. Clearchus advised Cyrus not to expose his own person, but he rejected the counsel. As soon as the enemy approached, the Greeks attacked them with such vigour that the disorderly and ill assorted army of the king forthwith took to flight. While Artaxerxes was preparing to attack in the flank, Cyrus advanced against him with a large body of horse, and with his own hand killed Artageræes, the captain of the king's guards, and routed the whole troop. Just at this moment, spying the king himself, and crying out, 'I see him,' he rushed forward and engaged with him in close combat. He killed his brother's horse and wounded the king himself. The king mounted another horse, but Cyrus attacked him again, and gave him another wound, and was in the act of giving him a third, when he himself was slain. The select guards and friends of Cyrus, not choosing to survive their master, killed themselves on his body. With the life of Cyrus ended the cause in which he died, and the Greeks effected their retreat under the command of Xenophon and others. [ANABASIS.] The whole expedition occupied fifteen months.

The character of Cyrus is highly eulogized by Xenophon (*Anab.* i. c. 9). In his childhood and youth he excelled all his companions in those pursuits which belonged to their rank: he was fond of war and hunting. His justice was conspicuous in all his conduct both public and private, and he never suffered the evil-doer to go unpunished. To those who deserved reward for services he was unbounded in his

munificence, and his friends received frequent tokens of his kind remembrance. On the whole it was the opinion of Xenophon that no individual had ever secured the affections of a greater number of men whether Greeks or others. According to a passage in Xenophon quoted by Cicero (*De Senectute*, c. 17), Cyrus was fond of agricultural and horticultural labours, and worked with his own hands. (Xenophon, *Anabasis* i.: Plutarch, *Artaxerxes*; Diodorus Siculus, xiv.)

CY'RUS, the name of several, Asiatic rivers, and apparently the same name as that of the Persian conqueror. The Cyrus, now the Kur, flows from the Caucasus into the Caspian Sea (Strab. Casaub., p. 501), and another river of the same name flowed past Pasargadæ. (Strab. 729.)

CYSTINGIA (Zoology), a sub-genus of the natural group of *Tunicata*, established by Mr. W. S. Mac Leay, who observes that it comes nearer to *Boltenia* than to any other hitherto described, and that they may prove eventually to be only two subgenera, of which we want the intervening links to enable us to form an accurate notion of the genus to which they belong. The characters, however, adds Mr. Mac Leay, both internal and external, are so different from those given as generic by Savigny to *Boltenia*, that it is impossible to assign it to this group, which indeed has nothing in common with it but externally a pedicle, and internally composite tentacula.

Subgeneric Characters.—*External.* Body with a subcoriaceous test, affixed by the summit to a very short pedicle, which is in the same line with the two orifices. The *Branchial orifice* quadrifid and lateral, the *anal* irregular and terminal; both being so little prominent as not to alter the form of the body. *Anatomical.*—*Branchial pouch* membranaceous, indistinctly reticulated, and divided into longitudinal folds. The *tentacula* of the branchial orifice composite. *Intestinal canal* lateral. *Stomach* very large, extending almost the whole length of the body. *Ovaries* two, composed of globular ova disposed in free racemes on each side of the body, with the branchial pouch and stomach between them. (W. S. Mac Leay.) Example, *Cystingia Griffithsii*.

Description.—*Envelope* semipellucid, yellowish. *Mantle* very thin, and provided near the branchial and anal orifices with a reticulation of circular muscles nearly at right angles to each other. *Tentacula* about 10 or 12, compressed and laminated like those of the genus *Boltenia*. *Branchial pouch* having its net-work exceedingly lax, meshes irregular and indistinct, but apparently simple, the nervures being nearly of the same size. The longitudinal folds of the branchiæ, or rather (owing to the singular position of them in this genus) their transverse folds, about 14 or 15 in number. Length of the body, half an inch. (W. S. Mac Leay.) Locality, Winter Island. Mr. Mac Leay, who has named the species after William Nelson Griffiths, Esq., who found only one specimen during the third voyage under Captain (now Sir Edward) Parry, gives the following details of its organization.

'The body of this animal, so different in many respects from all other *Tethyæ*, is pyriform, and attached to a pedicle so short as scarcely to curve down farther than the branchial orifice. This pedicle is rather conical at its base, subcylindrical, and apparently very weak at its extremity. From this apparent weakness and imperfect formation of the pedicle, in conjunction with the circumstance of one side of the conical part in the only specimen that I have seen being incrustated with sand, I suspect that the animal can scarcely be said to be suspended by its pedicle, but rather reposes on the conical part of it; by which means the folds of the branchial pouch will take a vertical, and the stomach a horizontal position, and thus be more in correspondence with the ordinary position of the stomach in the simple *Ascidicæ*, which is very rarely descending. The envelope of *Cystingia Griffithsii* is exceedingly smooth, and so pellucid as to appear almost gelatinous. The original colour I cannot ascertain; but if it be the same as that of the specimen in spirits, it is cinereous, rather yellowish. The external orifices have scabrous veins, are very minute, and scarcely at all prominent. The branchial orifice is quadrifid, and placed exactly half-way down the side. The anal orifice is on the same line with it and the pedicle, but is placed opposite to this last, so as to be terminal, having its external surface apparently without rays; in both respects being totally different from the anal orifice of *Boltenia*.'

Respiratory System.—‘The entrance of the branchial cavity is provided with a circular range of 10 or 12 unequal tentacula, which are composite or divided into laciniae at the extremity, which laciniae are again so minutely divided as to be almost plumate. The branchial pouch has about 14 folds, and its net-work is very indistinct and lax, the transverse nervures being perhaps the most visible, particularly towards the branchial orifice. The folds of the branchiae are most easily seen on the inside of the branchial pouch.’

Circulating System.—‘The heart is situated horizontally between the lower part of the tunic and the stomach. It is large, ovoidal, and appears to be composed of several lobes, and is indeed of a structure different from that of such *Ascididae* as are known.’

‘The dorsal sulcus is remarkably distinct, and proceeds from the immediate vicinity of the heart, or rather along the back of it to that of the branchial orifice. It may be seen through the external envelope of the body, when this is viewed on the left side, and forms an arch inclosing a lesser and more pointed arch, which last appears to be nothing else than one of the folds of the branchial pouch. At the point where this last arch touches the dorsal sulcus, there is in our specimen an orifice opening internally, and apparently communicating by a tube with a beautifully diaphanous longitudinal pouch, which contains nothing but two blackish nodules, one of which is longer than the other.’ The imperfection of the only specimen which Mr. Mac Leay had for examination prevented him from accurately ascertaining the nature and use of this part of the organization, which, he says, appears to have nothing similar to it in any of the other *Tunicata* hitherto observed.

Digestive System.—‘The *Pharynx* is situated rather higher than the branchial orifice; and the *oesophagus*, which is about half the length of the stomach, after descending to the highest part of the branchial vein, descends, and gives rise to a simple but enormous stomach, with very slight transverse striæ, and having a longitudinal division, marked somewhat deeply, and which runs almost the whole length of the body in a line between the base of the pedicle and the anal orifice. The intestine is exceedingly short, and apparently descending in a line with the stomach; the rectum is cylindrical, and anus simple. Such at least is the description of the digestive apparatus of this animal, if we give the name of pharynx to that end of the intestinal canal which opens into the branchial cavity, and the name of anus to that end of it which is free; and there is no doubt that such a description makes it an animal totally different from *Boltenia*, and in fact from all other species of *Tethyæ*, not only with respect to the singular form of the intestinal canal, but inasmuch as the branchial vein is thus placed, in relation to the pharynx, directly opposite to its position in all other animals of this group. I therefore am induced in some measure to suppose that there is a monstrous formation in the intestinal canal of the only specimen which I have had the means of examining; a supposition which must of course for the present throw doubt on any generic character which might be drawn from the above description of the intestinal canal. If indeed we could imagine that, were it not for some monstrosity of structure, the intestinal canal would communicate with the branchial cavity by that end which, from its being free, I have been obliged to consider the anus, then the whole of the internal organs of nutrition would have a situation analogous to that of those of *Boltenia*. For instance, there would then be a short *oesophagus* opening near the anal orifice of the envelope, an ascending stomach, a long curved intestine, and descending rectum, while the branchial vein and heart would take their usual situation in respect to the pharynx and stomach. We know moreover, from those memoirs of Savigny, to which I have in the course of this paper had occasion to refer, that the digestive organs of the *Tunicata* are subject to analogous derangements, of which he has figured two remarkable examples in *Cynthia Momus* and *Phallusia turcica*. It appears indeed to be a consequence of the low rank of these animals in the scale of being, and of their simple organization, that the organs apparently most essential to their existence may undergo the greatest inversions without affecting their life; for the monstrous *Cynthia Momus* described by Savigny, as well as the *Cystingia* now under consideration, had its ovaries full of eggs.’

Mr. Mac Leay observes that Pallas, in the *Nova Acta*

Petropolitana, has described, under the name of *Ascidia globularis*, a species of this family, which he found during his Siberian journey plentiful on the shallow sandy shores of the Arctic Ocean. The description of Pallas, as Mr. Mac Leay remarks, is vague, and principally differs from the species now under consideration in the size and position of the apertures. It is therefore, Mr. Mac Leay adds, just possible that the species which Pallas describes as being of the size of a large cherry, and attached by a very short peduncle to the fine sand of those shores, the particles of which being agglutinated to its surface, make the animal appear rough, may be identical with *Cystingia Griffithsii*, which would be rather interesting in a geographical point of view; but if both the apertures of Pallas's species be truly terminal, and the position of the peduncle be truly indicated in the figure, it is not only a different species, but probably a very different genus.

[*Cystingia Griffithsii*.]

1, nat. size, seen on the right side; 2, magnified, seen on the left side; A, anal orifice; C, branchial orifice; S, grains of sand externally encrusting the thick end of the pedicle.

For an illustration of the interesting anatomical details, we must refer to *Linn. Trans.*, vol. xiv., tab. 19, whence the figures and description are taken.

Mr. Griffiths's specimen was taken in Fox's Channel, and two specimens were obtained by the late expedition under Captain Sir John Ross, near Felix Harbour; but as these were abandoned with the rest of the collection, it is probable, as Captain James Ross observes, that the individual from which Mr. Mac Leay's description and drawings were taken is the only specimen ever brought to England.

CYTHE'RA. [CERIGO.]

CYTHERÆA. [VENERIDÆ.]

CYTHERI'NA. [BRANCHIOPODA, vol. v., p. 341.]

CYTINA'CEÆ, a small natural order of Rhizanth, the type of which is *Cytinus Hypocistis*, a parasite found growing on the roots of certain kinds of *Cistus* in the south of France. Its stems are a few inches high, thick, succulent, reddish or yellowish, and covered by straight fleshy imbricated scales which are only abortive leaves. The flowers are nearly sessile, erect, arranged at the summit of the stem, yellowish and velvety on the outside. The fruit is baccate, inferior, leathery, divisible into eight polyspermous lobes. The inspissated juice is used in French phar-

[*Cytinus Hypocistis*.]

1, a male flower; 2, a section of the same, very much magnified; 3, a female flower; 4, a section of the last.

macy as a styptic, but it is not admitted with us. Along with this genus are associated the curious genus *Hydnora*, Cape of Good Hope, which looks like a great star of the *Lycoperdon*, *Apodonthus*, a minute parasite upon the branches of trees, and two other less known genera.

CYTISUS, a genus of hardy papilionaceous shrubs, natives almost exclusively of Europe and the temperate parts of Asia, bearing ternate leaves, and with one exception, *C. purpureus*, yellow flowers. The species are common ornaments of our gardens; the most remarkable are the two kinds of Laburnum, *C. Laburnum* and *C. Alpinus*: these two plants form small well-known trees, which in spring are loaded with their numerous bunches of yellow flowers. They have a handsome hard olive-green wood, well adapted for the purposes of the turner; both are natives of the Alps of Europe, and are much alike; but *C. Alpinus* has the broader and more shining leaves of the two, and is much the handsomer plant. It is not a little singular, that the seeds of these species, in an order of plants usually wholesome, are decidedly and dangerously poisonous, owing to the presence of the deleterious alkaline principle called Cytisine.

The Cytisus of Virgil was the *Medicago arborea* of botanists.

CYTISUS SCOPA'RIUS, or **BROOM**, a shrub extremely common on uncultivated ground, heaths, &c., of most parts of Britain. The young tops or twigs when bruised, have an unpleasant odour, and a disagreeable nauseous taste. The seeds are emetic, and probably contain cytisine, an alkaloid found in the seeds of the Cytisus Laburnum, which possesses emetic, and, in large doses, poisonous properties.

Broom-tops boiled in water form a decoction which acts both on the bowels and kidneys. It is unquestionably a valuable diuretic, and many obstinate cases of dropsies have yielded to the use of this indigenous remedy which had resisted other means. Its diuretic properties may be increased by the addition of juniper berries and dandelion, to form the decoction, as now directed in the Pharmacopœia, and by adding to each dose, acetate, tartrate, or bitartrate of potash.

CY'ZICUS (Κύζικος), an antient town of Asia Minor, built on an island in the Propontis near the coast of Mysia, which was joined to the main land by two bridges. An isthmus has gradually formed itself, and the island is become a peninsula. It is said to have been a Milesian colony, formed in the eighth century B.C. Strabo (Casaub. 675.) speaks of Cyzicus as worthy of being numbered among the first cities of Asia for its size, beauty, and splendour, and for the goodness of its laws. It became early allied to Rome, and remained faithful in its alliance. It withstood all the power of Mithridates who besieged it, and the brave resistance of the citizens gave time to L. Lucullus to come up with his army and drive him back into Pontus. The Romans, grateful for the fidelity of Cyzicus, not only respected its liberties, but gave it an increase of territory, which extended, according to Strabo, to the east, as far as the lake Daseylitis, and to the west, beyond the *Æsepus* into Troas as far as Adrasteia. To the south, it reached Miletopolis. The town of Cyzicus was built partly on the sea-coast, and partly on a hill; its site has been described by Pococke and Sestini; there are some remains, and among others, an amphitheatre. On the same island, west of Cyzicus, was another Greek colony called Artace.

[Coin of Cyzicus.]

British Museum. Actual size. Bronze. Weight, 229 grains.

CZAR, or **TZAR**, the Russian title of the monarch of Russia. Some have supposed it to be derived from Cæsar or Kaiser, but the Russians distinguish between Czar and Kesar, which last they use for emperor. The sovereign of Russia styles himself also Autocrat of all the Russias.

It is only since the time of Peter the Great that the title of emperor has been given to him by the senate, and afterwards by the other courts of Europe. Before Peter's time, the sovereign of Russia was styled grand duke in European diplomacy. The consort of the czar is styled czarina.

CZASLAU, a circle in the eastern part of the kingdom of Bohemia, bounded by the circles of Chrudim, Kaurzim, and Tabor, and the margraviate of Moravia. Its area is about 1260 square miles, and it contains nine towns, Czaslau, Deutsch-Brod (4450 inhabitants), Kutteneberg (8000), Kank, Humpoletz, Chotiberg (2000), Przemislau (1400), Pollna (1800), and Golz-Jenikau, 33 market towns, and 840 villages. The population is about 234,260: in 1817 it was 187,120. The surface is undulating, with numerous levels, except on the side next Moravia, where it is mountainous. In the northernmost parts it is intersected by the Elbe, which is here increased by the Dobrava; and from west to east it is traversed by the Sazova. Much corn and flax are raised; it yields timber, silver, iron, saltpetre, garnets, and other precious stones, &c.; and has woollen, cotton, paper, &c. manufactories.

CZASLAU, the chief town, lies in a fertile plain, in 49° 52' N. lat. and 15° 25' E. long. It is an antient town, has a collegiate church, embellished with the loftiest steeple in Bohemia, a public school, manufactures of saltpetre, linens, &c. and it contains about 3400 inhabitants. The monument in memory of J. C. von Trocznow, more commonly called Ziska, the celebrated leader of the Hussites, who died in 1424, was once in the church, but all vestige of it has been removed.

CZEGLE'D, a large market-town in the county of Pesth in Hungary, and circle of Ketskemet, is the property of the established or Roman Catholic church. It lies in 47° 10' N. lat. and 19° 48' E. long., has a Roman Catholic and Protestant church, several handsome buildings, and contains about 13,050 inhabitants, 8500 of whom are Protestants and 4400 Roman Catholics. The country around it is well cultivated, and produces much grain and a great quantity of common red wine. The breweries are considerable.

CZERNIGOF, or **TSHERNIGOF**, formerly part of the Ukraine, is at present one of the three governments of that part of the south of Russia in Europe which is called Little Russia. It lies between 50° 20' and 53° 20' N. lat. and 30° 10' and 34° 40' E. long. It is bounded by the governments of Mohilef, Smolensk, Orel, Kursk, Pultava, Kief, and Minsk, and contains an area, according to Neumann, of about 27,000 square miles, which, however, Wichmann reduces as low as 20,920 and Arsenief to 19,950. The general character of the surface is a level, occasionally interrupted by hills, and rising into high land as it approaches the elevated banks of its south-west boundary, the Dnieper. With the exception of some sandy tracts, the subsoil is sand or clay, which is well covered with rich loam, and presents a succession of luxuriant arable and pasture lands. On the banks of the Dnieper, the chalk, slate, and clay alternate, but slate predominates. Most of the streams which water Czernigof empty themselves into the Dnieper, particularly the Desna, a navigable river, which enters the country in the north-east from Orel, and traverses it nearly in its whole length in a south-westerly direction. The waters of the Desna are increased by those of the Snof, Ostre, Seim, and Sudost; the Sofda also flows through the northernmost, and the Trubesh through the southernmost districts. Czernigof abounds in small streams, and in natural sheets of water, none however large enough to be called lakes; it has mineral springs, but they have not been brought into use. The climate is dry, mild, and salubrious; but the land has of late years suffered from the inroads of locusts. Agriculture and grazing constitute the principal pursuit of the inhabitants; corn of all kinds, particularly rye, barley, and oats, are grown, and the yearly produce is estimated at three millions of quarters, of which upwards of two millions are consumed in the country itself. Hemp in large quantities, flax, tobacco, peas and beans, linseed, and hops, are also raised. Vegetables, melons, and the commoner sorts of fruit are plentiful, but the grape does not ripen sufficiently for wine. There is here a peculiarly fine species of the cherry, called Tsherasun, from which brandy and sugar are obtained. The woods and forests yield an abundance of excellent timber, charcoal, potash, and tar. Horses and cattle are reared in great numbers; the horse is of the

small, active, and hardy breed of the Ukraine, and well adapted for the use of light cavalry, and there are fine studs kept, particularly by Count Rasumofsky. The ox is of a fine race, and fattens readily; this animal here performs the labour of the plough exclusively. Large herds of sheep and swine are kept. Much honey and wax are made. Of minerals, Czernigof possesses iron, alum, saltpetre, porcelain earth, potter's-clay, chalk, and slate.

According to the census of 1796, the twelve circles of which Czernigof was then composed, contained a population of 1,013,600 souls; its present amount is estimated at 1,410,000. The average increase during the three years 1825, 1826, and 1827, was 49,121 in each year. There are scarcely any serfs in this government. The Greek is the predominant form of faith, and ecclesiastical affairs are directed by the archbishop or eparch of Czernigof and Neshin, who has 1016 parishes under his jurisdiction.

The inhabitants mostly make their own clothing and utensils. There has, however, been an improvement in this respect; in 1808 the whole country could not produce above fifteen manufactories, but in 1830 the number had increased to seventy-seven, which gave employment to 3095 operatives. The fondness of the people for ardent spirits has occasioned the establishment of a great number of distilleries. There is some internal trade, which mostly centres at Neshin, where four large fairs are held in the course of the year. The exports, consisting principally of horses, cattle, swine, tallow, wool, skins, bristles, grain and meal, honey and wax, potash, hemp and hempseed, and brandy, are considerable.

Czernigof is one of the privileged governments, the antient prerogatives of the nobility having been confirmed to them in 1802, and the Cossack inhabitants enjoying the privilege of distilling brandy in any spot they please, without its being deemed an infringement on the crown monopoly. The governor-general of Little Russia is at the head of the local administration of Czernigof, as well as Pultava and Kief, and the revenues of the government are said to produce about 200,000*l.* sterling per annum.

The country is divided into the fourteen circles of Czernigof, Gorodnia (capital Gorodnick on the Gorodna, three churches, and about 1300 inhabitants), Sosniza (capital of the same name, at the confluence of the Ubeda and Desna, 1200 inhabitants), Koselez (capital Koselez, on the Oster, 2,100 inhabitants), Neshin (capital Neshin, on the Oster, fifteen churches, and upwards of 10,000 inhabitants who carry on a large trade), Borsna (capital Borsna, on the river Borsna, about 1000 inhabitants), Konotop (capital Konotop, on the Yesatsha, about 1000 inhabitants), Gluchof (capital Gluchof, on the Irsmen, twelve churches, and about 9000 inhabitants), Novgorod-Seversk (capital Novgorod-Seversk, on the Desna, 8000 inhabitants), Starodub (capital Starodub, on the Babinga, about 4300 inhabitants), Novomiasto (capital Novomesto, on the Iput, about 1100 inhabitants), Mglin (capital Mglin, on the Sudenka, four churches and about 2500 inhabitants), Souragia, and Krolevertz.

CZERNIGOF, the capital of the government, is situated on the elevated banks of the Desna, in 51° 27' N. lat. and 31° 15' E. long. It is surrounded by a rampart of earth which is now converted into walks. It was built in the year 1024, and is accounted the oldest town in European Russia. In its centre stands a high hill with a castle on its summit; it has several churches, among which is the cathedral, a well-built edifice, in which the remains of St. Theodosius are deposited. There are also four monasteries, a gymnasium, an ecclesiastical seminary, with a printing establishment attached to it, an Imperial orphan asylum, a riding-school, a mechanics' school for 400 pupils, and several establishments for the indigent. Usevolofsky states the population to be about 7000, but others carry it as high as 10,000; the inhabitants are chiefly employed in retail trade and mechanical pursuits, and manufacture small quantities of woollens, linens, leather, and soap. Four markets are held here in the course of the year. It is the residence of the archbishop of the diocese or eparchate.

CZERNOVITZ or CZERNOVICS; one of the counties or circles of the kingdom of Austrian Galicia; it formerly constituted what was called 'the Buckowine,' being that portion of Moldavia which the Porte ceded to Austria in the year 1777. This country, though now incorporated with Galicia, has retained its old legislative institutions. The Moldau borders it on the south and east, and Transylvania on the south-west. Its surface, which comprises an area of about 3090 square miles, is intersected in all

parts by well-wooded branches of the great Carpathian range. The intervals between the lines of mountains are broad and productive valleys, fertilized by the Pruth, Sereth, Moldau, Czeremosh, Suczava, Golden Bistriza, &c., and yield rich crops of corn, flax and hemp, potatoes, and fruit. Grazing is also carried on upon an extensive scale. The forests abound in beeches, pines, and firs, which afford valuable timber, but the oak is of very partial growth. The Buckowine is rich in minerals, particularly salt, which the works at Karzike alone produce in sufficient quantity to supply its whole consumption. The gold-dust of the Bistriza does not at present yield enough to defray the cost of collecting; but silver, lead, copper, and iron, are obtained from the mines near Kirlibaba (about 560 marks of silver, and 50 tons of lead), Poszoryta about 1000 cwt. of copper, and Jacobeny about 1200 tons of iron. There are three glass-works, and several potash manufactories and brandy distilleries, in this county. The Buckowine was in a very wild and barbarous state when it was first annexed to the crown of Austria, but has been rapidly advancing in civilization and prosperity ever since. The inhabitants differ both in descent and religion from their Galician neighbours; they are chiefly of Wallachian extraction, and profess the Greek religion. A vast number of Armenians, Jews, Hungarians, and Germans, besides about 8000 Philippones from the Crimea, who sought refuge here in Joseph II.'s time, and settled in and around Dragowesna, have intermixed with them. The whole population in 1817 amounted to 201,319, and consisted of 41,864 families; in 1825 it was 261,162; and at the present day it is about 280,000. Of municipal towns there are 3; market-towns 3; and villages 274. The three municipal towns are Czernovitz, the capital; Suczava, with 4 churches, a synagogue, and about 5200 inhabitants; and Sereth, with 3 churches, and about 3100 inhabitants.

CZERNOVITZ, the capital of the Buckowine, and of the present circle of Czernovitz, is situated on a hill close to the right bank of the Pruth, in 48° 25' N. lat., and 25° 39' E. long. In the centre of the town is a spacious square, with the main street passing directly across it. Although there are many handsome private houses and public edifices, such as the Greek cathedral, the Roman Catholic collegiate church, the hospital and government buildings, &c., Czernovitz itself is an indifferently constructed town, and the remote quarters are composed of narrow rows of low wretched hovels. The number of houses is about 900, and of inhabitants about 7300, including above 1200 Jews. Czernovitz is the residence of a Greek bishop, and seat of a Greek consistory; it has a philosophical academy, conducted by a director and seven professors, a gymnasium, a head district school, an ecclesiastical seminary, courts of justice, &c. Mechanical pursuits, and a considerable trade in native and other productions with Moldavia, Wallachia, and various quarters of Germany, contribute greatly to the prosperity of the town.

CZIRKNITZ (ZIRKNITZ), a market-town in the circle of Adelsberg, duchy of Carinthia, in Illyria. It lies on the Brohitza, contains 240 houses, and about 1,300 inhabitants, who are occupied in fishery, and in salt and tile-making: 45° 38' N. lat., 14° 25' E. long.

Near it is the singular lake of the same name, in closed within limestone mountains of very grotesque outlines. The lake in dry seasons is from 12 to 15 miles in circumference, and when quite full about 24 miles; its entire area is then about 63 square miles. Its form however is made very irregular by numerous bays, capes, and islands. At the foot of the Javoring, which rises on its southern bank, the peninsula of Dervoseck stretches far into the lake; on the west is the island of Vorneck, on which is the village of Ottock, the inhabitants of which cultivate millet and vegetables. While passing over the more shallow parts, the rocky bottom of the lake presents a very dark appearance, occasioned by numerous funnel-shaped cavities of various dimensions. All these cavities have peculiar and for the most part significant names; such as Kottu (the kettle), Betscheck (the tub), Reitie (large corn sieve), Rescheto (coarse sieve), Sittarza (fine meal sieve), Vadonos (water carrier), &c. Its depth, compared with other lakes, is inconsiderable: the Cave of Rescheto, the deepest part of the whole lake, is at the lake's mean height only 56 feet; Vadonos 50, Velka Bubnarza 45, Kottu 38; the others are from 29 to 6 feet deep. The lake is remarkable for great variation in the height of its water, which is owing to the nature of the limestone rocks. The

bottom of the lake, especially of the funnels, is full of clefts and fissures, through which the water passes at forty different openings into subterranean caverns and channels, and reappears under the form of the Bistriza and Baronniza in the valley of Laibach. During the dry season, which generally occurs in autumn, the bottom of the lake is covered with luxuriant herbage, which is made into hay. Only a very small portion of the lake however is susceptible of cultivation; millet and buck-wheat are sown, which ripen in six weeks; but as the waters of the lake frequently do not subside for three, or even more years, the sowing and harvest are of course very irregular. In January, 1834, the waters left the lake, and did not return till March, 1835. During the interval grain and vegetables were sown and gathered, and cattle grazed on the bottom of the lake—an occurrence which, for the long cessation of the waters, is said to be unprecedented.

The lake abounds in fish, chiefly pike and the *Cyprinus tinca*, Lin.: they are caught in pits, at the rising of the lake, with drag and small hand-nets, and are sent alive to Laibach and other places, or dried. The lake is also frequented by numerous aquatic fowl, which, like the fishery, form an important means of subsistence to the inhabitants. In the environs of the lake, which are exceedingly picturesque, are nine villages, twenty churches, and two castles.

CZORTKOV, a county in the kingdom of Austrian Galicia, having Russia for its eastern boundary, and Moldavia and the Buckowine for its southern. Its area is about 1344 square miles; and its population, which was 149,488 in 1817, is at present upwards of 176,000. With the exception of a tract between the Pruth and Dniester, once part of the Buckowine, its surface is a uniform level, fertilized by the waters of the Sered, Striva, Dzurym, Dupa, and other rivers, and highly productive, particularly in most kinds of grain, tobacco, aniseed, and maize: there is abundance of timber; but the breeding of cattle is neglected. Wax and honey are made in great quantities. Manufacturing industry is limited to coarse woollens. Zaleszczyky, an ill-built place, but beautifully situated on the Dniester (in 48° 53' N. lat., and 25° 45' E. long.), is the chief town; it has a chapter-house, collegiate church, Protestant place of worship, monastery and head school: the population is about 5500, including about 3150 Jews. The second town is Czortkov, on the right bank of the Sered, with a castle, and government tobacco manufactory, a monastery, and about 2300 inhabitants; and the third town is Husiatyn, on the Podhorze, with an old castle, and about 1540 inhabitants, two-thirds of whom are Jews. Besides these, the circle contains 19 market-towns, and 242 villages.

D.

D, which occupies the fourth place in the Hebrew alphabet and those derived from it, is the medial letter of the order of dentals or palato-dentals. It readily interchanges with those of the same organ. The German language and the English offer an abundance of examples.

1. *D* in German corresponds to *th* in English, as *dein*, thine; *denk-en*, think; *du*, thou; *dieb*, thief; *donner*, thunder; *dorn*, thorn; *durch*, through; *tod*, death; *bruder*, brother; *erde*, earth; *leder*, leather, &c. And on the other hand, *th* in German, which however is not pronounced as among us, corresponds to *d* in English, as *thau*, dew; *thal*, dale; *thaler*, dollar; *thu-n*, do; *that*, deed; *theil*, dole and deal; *roth*, red; *noth*, need; *muth*, mood.

2. *T* in German to *d* in English, as *tag*, day; *taub*, deaf; *taube*, dove; *tief*, deep; *traum*, dream; *tod*, death; *brot*, bread; *breit*, broad; *wort*, word; *bart*, beard.

3. *D* in Latin to *z* or *ss*, or *s* final in German, and *t* in English, as *decem*, *zehen* or *zehn*, ten; *digitus*, *zehe*, toe; *duo*, *zwey*, two; *lingua* (the same as *lingua*), *zunge*, tongue; *dens* (*dent*), *zahn*, tooth; *cor* (*cord-is*), *herz*, heart; *duc-ere*, *zieh-en*, tug; *doma-re*, *zahn-en*, tame; *sud-or*, *schweiss*, sweat; *pes* (*ped-is*), *fuss*, foot; *ed-ere*, *ess-en*, eat; *clud-ere*, *schliess-en*, shut; *od-it*, *hass-en*, hate; *quod*, *was*, what; *id*, *es*, it; *grandis*, *gross*, great.

4. *D* is interchangeable with *l*, and this most freely. Compare the Greek forms *Ὀδυσσεύς*, *Πολυδευκής*, *δαφίλης*, *δακρυ-ω*, *δε-ω*, with the Latin *Ulixes*, *Pollux*, *lapisilis*, *lacruma*, *liga-re*. In the Greek language itself compare *δεῖδω* with *δαῖδος*, *δαλος* with *δας* (*δαδ-ος*); and in the Latin, *sella*, *scala*, *mala*, *ralla*, with the verbs *sede-o*, *scand-o*, *mand-o*, *rad-o*. *Vesidia* and *Digentia*, two small streams of antient Italy, are now called respectively *Versiglia* and *Licenza*. So the Italians say either *edera* or *ellera* for ivy; and the Latin *cauda*, a tail, is in Italian *coda*, in Spanish *cola*. But one of the most remarkable instances of this change exists in the words *eleven* and *twelve*, in both of which the *l* has grown out of a *d* in *decem*. In the same way, while the Greek has *δεκα* for ten, the Lithuanian prefers *lika*; and of two Sanscrit dialects, one has *dasan*, the other *lasan*, for the same numeral. The people of *Madrid* call themselves *Madrilenos*.

5. *D* attaches itself to the letter *n*. Thus we find Gr. *τειν-ω*, and Lat. *tend-o*, stretch; Lat. *canis*, Eng. *hound*; Lat. *sonus*, Eng. *sound*; Lat. and Gr. root *μεν* or *men*, Eng. *mind*; Ger. *abend*, Eng. *even* or *even-ing*; Ger. *donner*, Eng. *thunder*; Ger. *niemand*, Eng. *no-man*. And our English term *husband*, is a corruption of *house-man* (Lat. *dominus*). This *d* is particularly apt to insert itself after an *n* when an *r* follows. Thus from the Latin *ciner-is*, *gener*, *tener*, come the French *cendre*, *gendre*, *tendre*. And the latter language has the futures *viendrai*, *tiendrai*, where analogy would have led to *venir-ai*, *tenir-ai*.

6. *Di* before a vowel is changed into a *g* or *j*, as *Dianus* or *Janus*, the god of light (dies) in Roman mythology; *Diana* or *Jana*, the goddess of light. So *Diespiter* and *Jupiter* are the same name. The Latin *hodie* is in Italian *oggi*. Sometimes a *z* is preferred to a *g*, especially in the Greek, Italian, and German languages. In the Greek, for example, *ζα* is used for *δια*; hence *ζω*, *vivo*, and *διαίτα*, are connected, and the same town on the African coast is called indifferently *Hippo Zarytus* or *H. Diarrhutos*.

7. *Du* before a vowel is changed into *b* or *v*. [See B.] With this principle is connected the change of *d* into *v*, in the words *suavis*, *suadeo* and *ἀδύς*, *clavis* and *claudio*, and the river *Suevus* or *Oder*.

8. Instances occur where *d* is interchanged with both the other medials; with *b*, as in Latin *barba*, *verbum*, English *beard*, *word*; with *g*, as in the Greek *Δημητῆρ* from *γημητῆρ*, *πηδός*, 'the beech,' as well as *φῆγος*, and in the two names of the African city, *Καρχηδών* and *Carthago*. One may often hear in the mouths of children *dood* for *good*, and *do* for *go*.

9. *D* when flanked by vowels often disappears in the transition of words from Latin into French. Compare *Melodunum*, *Ludovicus*, *vadium*, *vādis*, *medius*, *fides*, *nudus*, *cauda*, *assidere*, *videre*, with *Melun*, *Louis*, *gué*, *vas*, *mi*, *foi*, *nu*, *queue*, *asseoir*, *voir*.

For the forms of the letter **D** see ALPHABET.

D as a Roman numeral signifies five hundred. It is more correctly written **IƆ**. [NUMERALS.]

D (in Music), the second note or degree of the diatonic scale, answering to the *re* of the Italians and French.

DABCHICK. [DIVERS.]

DA CAPO (from the head, or beginning), an Italian musical term, signifying that the first part, or strain, is to be repeated, and to conclude at the sign of the pause (⌞), or at the word *fine*. The phrases in use are, *Da Capo al fine*, and *Da Capo al segno*; i. e., 'From the beginning (or over again) to the *fine*,' or 'to the sign.' This term is abbreviated by the letters **D. C.**

DACCA JELALPORE (Dhaka), one of the districts into which the province of Bengal is divided; it lies between 23° and 25° N. lat., and between 90° and 91° E. long., and is bounded by the district of Mymensingh on the north, by Tipperah on the east, by Tipperah and Backergunge on the south, and by Rajeshahy and Jessore on the west. The limits of this district were much more extensive before the year 1800 than they are at present, reaching as far south as the sea, and as far north as the Garrow mountains. It then contained an area of more than 15,000 square miles, but it is now reduced to somewhat less than 6000 square miles. The surface of this district is uniformly low and level, and being intersected by the Ganges and Brahmapootra, a great part of the lands are periodically covered with water by the overflowing of those rivers during the rainy season. At these times the villages which are built on artificial embankments have the appearance of small islands. The deposits left by these inundations fertilize the soil. The lands are only partially cultivated: towards the north and west are very extensive tracts of jungle in which are great numbers of wild elephants which cause much damage to the neighbouring farmers, and prevent the extension of cultivation. Towards the south and the east nearly seven-eighths of the land are under cultivation, producing rice, betel-nut, hemp, cotton, and sugar. The abundance of the rice harvests has caused the district to be called the granary of Bengal.

Dacca is principally known in Europe for its manufactures of cotton goods. The striped and figured muslins of Dacca were long celebrated throughout the world. The beauty and delicacy of these fabrics were once unrivalled, but of late years the weavers of Paisley and Manchester have so successfully competed with those of Dacca, that a large proportion of the families in that district, who have for many generations employed themselves in their production, have been compelled to adopt other pursuits. Another reason for this change may be found in the altered condition of the former lords of the country, among whom the curious fabrics of Dacca were held in the highest estimation, and who are now unable to gratify their taste for expense.

The ruins of antient mosques and Hindoo temples are spread all over the country; and in many places are seen the remains of fortresses constructed to oppose the invasion of the Mughls, but they are all now dilapidated and the cannon rendered useless. The settled estates are mostly parcelled out into small talooks, or Zamindaries, and these are divided and sub-divided into very insignificant farms. The principal towns are Dacca, Rajnaghur, Narraingunge, Furreedpore, and Soonergong. Rajnaghur stands on the east side of the Puddah, the grand outlet of the Ganges, in 23° 22' N. lat., and 90° 25' E. long., 23 miles south by west from Dacca; Narraingunge stands on the west side of a branch of the Brahmaputra, about 8 miles south-east from Dacca, in 23° 37' N. lat., and 90° 35' E. long. This town contains a population of more than 15,000 souls, and is one of the greatest inland places of trade in Bengal. Salt, tobacco, indigo, and grain, are the principal objects of this trade. Numerous indigo factories are established on the banks of the river where the soil is favourable for the growth of the indigo plant. On the opposite, or east side of the river, is a Mohammedan mosque, to which great numbers of devotees resort from the neighbouring towns to see what is described as the foot-mark of the prophet of Mecca. Similar foot-marks are shown in several other places in India, and impart a peculiar sanctity to the buildings in which they are placed. Furreedpore is situated on

the south side of the Puddah, or great Ganges, five miles from its banks, and 40 miles from Dacca: it is the residence of the principal civil and judicial officers for the district. Soonerong stands on one of the branches of the Brahmapootra, in $23^{\circ} 39' N.$ lat., and $90^{\circ} 43' E.$ long., about 13 miles south-east from Dacca. This is said to have been in antient times a large city, and the seat of government before the building of the town of Dacca; it is now little more than a village; it was long celebrated for its manufacture of beautiful cloths, some of which are still made in the village.

The entire population of the district was stated in 1801 to be 938,712; one-half were Hindus and the rest Mohammedans. The condition of slavery is recognized, and slaves are sold and conveyed by deeds of sale, which are registered in the courts of justice in the same way as other conveyances of chattels are registered.

DACCA, the capital of the district just described, is situated on a branch of the Ganges, called the Booree Gunga (old Ganges), about 100 miles above the mouth of the river, in $23^{\circ} 47' N.$ lat., and $90^{\circ} 17' E.$ long. Dacca is comparatively a modern town. In 1608 the seat of government was removed to it by Islam Khan, then governor of Bengal; in compliment to the emperor, the name of the place was then changed from Dacca to Jehangire Nuggur. It is related that in 1689 rice was sold in the market of Dacca at the rate of 640 pounds for one rupee, and that to commemorate this fact the western gate was built up by order of the viceroy, Shaister Khan, and an inscription placed on it forbidding the re-opening of the gate until the price of this main article of food should be again equally low. Dacca was formerly a much more extensive place than it is now, and in the reign of Aurengzebe exhibited a considerable degree of splendour. The former limits of the city contain the ruins of many magnificent buildings, such as bridges, mosques, and palaces, but the places where these occur are for the most part overrun with jungle. Including the suburbs the town occupies a space six miles long, on the bank of the river, but it is not wide in proportion. The streets are narrow and crooked, and the houses, for the most part, are mean buildings. The native population in 1801 was estimated at about 200,000 souls, rather more than one-half of whom were Mohammedans and the rest Hindus. There are several Portuguese, Greek, and Armenian merchants settled in the place. In 1823 a society was formed for the support of Christian, Persian, and other native schools for males and females in the city of Dacca and its vicinity. This society took under its charge six schools, and in three years increased the number to twenty-five, which were attended by 1414 scholars. After a few years the funds of the society fell short, in consequence of their support being withdrawn by the wealthy natives. Under these circumstances a donation was made to the society by the government, but by no means equal to its wants, and the schools have in consequence greatly fallen off in numbers and efficiency.

DACE. [LEUCISCUS.]

DA'CELO. [KINGFISHERS.]

DA'CIA, the antient name of a country north of the Danube and south of Sarmatia, bounded on the east by the Pontus Euxinus, and on the west by the Tibiscus, now the Theiss. It was divided into Dacia Ripensis, Dacia Alpensis, and Dacia Mediterranea. The antient Dacia comprehended the modern Transylvania, Wallachia, Moldavia, and Bessarabia. The Daci were antiently called Davi, according to Strabo (p. 304, c.), and hence, he adds, the name Davus was commonly applied to a slave in Attica, many of the Athenian slaves being imported from the countries about the Danube. This appears from the plays of Terence, which were translated from the Greek, or at least founded on a Greek model. The change of the name has been explained in another place. [C, 2nd column.] The country was inhabited by the Daci and the Getæ: the Daci occupied the part towards Germany and the source of the Danube; the Getæ occupied the part towards the east and the Pontus. (Strabo, p. 304, c.) Both the Getæ and Daci spoke the same language. (Strabo, p. 305, a.) The Getæ were better known to the Greeks in consequence of their frequent migrations to the banks of the Danube. The Latin name Daci included the Getæ. The principal river of Dacia is the Tibiscus, which, with its tributary the Marisus, falls into the Danube. There are several small rivers besides, the Aluta (the Alt), the Aravus, and others, which also fall

into the Danube. The first expedition of the Emperor Trajan was against the Daci, headed by their king Decebalus, and the war, which lasted nearly five years, ended in their submission A.D. 105 (Dion Cassius, lxxviii.) to the Roman power. One of their chief towns, Sarmizegethusa, was afterwards called Ulpia Trajani, in memory of the victory which was gained. In A.D. 250 Dacia was overrun and conquered by the Goths, to whom it was afterwards resigned by the Emperor Aurelian. Domitian celebrated his pretended exploits against the Dacians by assuming the title Dacicus. (Juvenal, *Sat.* vi., 204.)

DACIE'R, ANDRE', was born at Castres in 1651, studied at Saumur under Tanneguy le Fèvre, whose daughter Anne he married in 1683. Both husband and wife became eminent among the classical scholars of the seventeenth century. They were employed with others to comment upon and edit a series of the antient authors for the dauphin, which form the collection 'Ad usum Delphini.' Madame Dacier's commentaries are considered as superior to those of her husband. She edited Callimachus, Florus, Aurelius Victor, Eutropius, and the history which goes by the name of Dictys Cretensis, all of which have been repeatedly reprinted, with her notes. She published French translations of the *Amphitryon*, *Rudens*, and *Lepidicus* of Plautus, with a good preface, of the comedies of Terence, of the *Plutus* and the *Clouds* of Aristophanes, and of *Anacreon* and *Sappho*. She also translated the *Iliad* and the *Odyssey*, with a preface and notes. This led to a controversy between her and La Motte, who had spoken slightly of Homer. Madame Dacier wrote, in 1714, 'Considérations sur les Causes de la Corruption du Goût,' in which she defended the cause of Homer with great vivacity, as she did also against Father Hardouin, who had written an 'Apology of Homer,' which was more a censure than an apology. The warmth however with which both the Daciers resented anything that was said against the antient writers was carried to the extreme, and had at times something ludicrous in it. But Madame Dacier's enthusiasm was real, and unaccompanied by pedantry or conceit. Neither did her learned lucubrations make her neglect her domestic duties as a wife and a mother; and she was generous and charitable towards the poor. She died in 1720, and her husband in 1722. The latter, besides his editions of the classics, translated also into French the works of Hippocrates, the *Œdipus* and *Electra* of Sophocles, the *Poetica* of Aristotle, and the lives of Plutarch, which last translation is inferior to Amyot's; he also translated Horace, but neither the translation nor the notes are much esteemed. The 'Bibliothèque des Anciens Philosophes,' 9 vols. 12mo., was published under Dacier's name, but he only furnished some of Plato's dialogues and the *Manual* of Epictetus. Dacier was member of the Academy of Inscriptions, secretary to the French Academy, and keeper of the Cabinet of the Louvre, and he had a pension of 2000 francs from Louis XIV.

DACNIS. Cuvier's name for a genus of birds (the Pit-Pits of Buffon) which, he observes, represent the *Carouges* (*Xanthornus*) in miniature, by their conical and sharp bill. Example, *Dacnis Cayana*.

Description.—Cærulean blue; forehead, shoulders, wings, and tail black. Locality, Mexico.

[*Dacnis Cayana*.]

This pretty little bird is the *Elotototl* of the Mexicans. Hernandez says that it lives about the trees of the Tetzcoacan mountains; that it is eatable; that it does not sing, and that therefore it is not kept in the houses of the inhabitants.

DACTYL is the name of a metrical foot consisting of a long and two short syllables, as the Latin word *littora*; or of an accented syllable followed by two unaccented, as *gallery*.

DACTYLICS. To this term belong all those metres which consist of a repetition of dactyls or equivalent feet. The long syllable may be the first in the line, as it is in the heroic verse of Homer; or it may be preceded by one or two short syllables. Thus the modern anapestic verse is strictly a dactylic metre, as—

'If he ha'd any fau'ls, he has le'ft us in dou'bt.'

Of the dactylic metres the most common are the hexameter, which, as its name implies, consists of six feet [**HEXAMETER**], and the pentameter, of five feet.

The dactylic metre often alternates with trochaic measures. Such is the case in the sapphic and alcaic stanzas.

DACTYLIS GLOMERATA, or Cocksfoot grass, is an extremely common plant in fields and waste places, growing and flowering during a great part of the summer. It has, in its wild state, a coarse bluish rough herbage, and a flower-stem about three feet high, divided at the point into a loose panicle, each of whose divisions bears a cluster of flowers at its end. The glumes are two, sharp-pointed, keeled, and rather unequal; they enclose from three to six florets, each of which consists of two rough-ribbed paleæ, the lower and outer of which is the broader, and tipped with a short bristle. In its uncultivated state this is a coarse hard grass; nevertheless, it is readily eaten by cattle, horses, and sheep: it strikes its roots to a considerable depth in the soil, and on this account is capable of enduring the drought of dry sandy exposed land. Hence, in such situations, where scarcely any other pasture can be procured, as in the naked brecks (or undulating downs) of Norfolk, it is of great value.

Mr. Sinclair assures us that Cocksfoot forms a part of the herbage of pastures most celebrated for fattening and keeping the largest quantity of stock in Devonshire, Lincolnshire, and the vale of Aylesbury; and he states that in the most skilfully managed of these pastures the foliage of the Cocksfoot was only to be distinguished by an experienced eye from the various species of fine pasture grasses with which it is combined. We would not however recommend any one laying down artificial grass to employ Cocksfoot, where other grasses can be made to succeed; for we have invariably found it overgrowing the sorts with which it was mixed, and forming coarse tufts, which neither feeding nor mowing have been able to keep down.

[*Dactylis glomerata*]

1, a spikelet much magnified; *a, a*, the glumes; 2, a floret with the paleæ.

DACTYLO'CERUS. [**PHROSINE**.]

DACTYLO'LOGY. The simple art of communicating ideas by spelling words with the fingers is called dactylology. The positions which the fingers are made to assume correspond to the alphabetic characters of a language, and the series of alphabetic signs is perhaps better known under the name of the manual alphabet. The chief, and the most useful application of dactylology is in the instruction of the deaf and dumb. In the various institutions for this class of persons, dactylology is almost universally employed. The letters may be formed by the two hands, or with only one hand: a two-handed alphabet is used in the English institutions; on the continent of Europe, and in America, the one-handed alphabet is employed. Both these alphabets are represented in vol. ii., p. 500, of the 'Penny Magazine.' By reference to these engravings, it will be seen that either of them may be learned by an hour's practice; they are often taught to the deaf and dumb, in conjunction with the written alphabet, in a few days.

Dactylology must not be confounded with the natural language of the deaf and dumb, which is purely a language of mimic signs. We mention this because some persons have misunderstood the office and overrated the value of finger-talking; imagining that all deaf and dumb persons naturally understand language, and converse with their fingers, and that, by acquiring the manual alphabet, they can communicate with them. Such persons should bear in mind that the deaf are shut out from all spoken languages; that before they can use or understand a written or spoken language, they must learn it; and that such an acquirement is made, under their disadvantages, by a very slow process. To the uninstructed deaf, dactylology is useful as a means of communication between them and their teacher; at first, in such select language as the pupil understands, or as may be readily explained by mimic signs or other auxiliaries. As the pupil advances in the knowledge of words and their collocations, this mode of communication becomes more satisfactory, and at length he can use it to converse on all ordinary subjects with the accuracy of writing and with much greater rapidity.

Dégérando has clearly and fully explained the use and value of this very simple art. (*De l'Education des Sourds-Muets*, Paris, 1827.) He says dactylology is to alphabetic writing what that is to speech. Formed upon writing as its model, it represents it precisely as writing represents words. But in this connexion between dactylology and writing, the reciprocal utility of the two orders of proceeding is at the same time the reverse of what we have remarked in the connexion between writing and speech. In fact, the office of dactylology consists in giving to writing that moveableness which speech enjoys, and which the first loses in the fixedness of depicted characters. Dactylology is writing set free from its material dress, and from those conditions necessary for the employment of the pen or pencil; it carries with itself these instruments; it is thus ready in all familiar conversations; it affords help at all times and in all places. It is thus that dactylology is little more than a toy for those who already possess, in speech, a means of communication more easy and more appropriate to all circumstances. It is thus also that it becomes an essential resource to those who are deprived of speech, to whom it renders a portion of those advantages, supplying for them writing, and giving it in some manner a new extension. However, dactylology is far from affording all the advantages of speech, while it loses a portion of those which are peculiar to the privilege of writing. On the one hand it is much less rapid than speech; it is unfurnished with that expression which belongs to the human voice—of that infinite diversity which the soul finds within for portraying all the sentiments which affect it; it has nothing of that harmony, that secret charm, that power of imitation of which speech is so capable; its employment, besides, obliges the suspension of all business and all action. On the other hand, it has none of that durability which renders writing so favourable to the operations of reflection; it is not able to exhibit its signs but after a successive manner; it cannot preserve in composing, as writing does, those vast pictures which the inventive faculty embraces simultaneously, and subsequently surveys, in every sense, with perfect liberty. Dactylology shares in some of the inconveniences of speech, and in some of those of writing; it is as fugitive as the first, it is as complicated in its forms as the second. (Vol. i., pp. 259, 60.)

The manual alphabet has been employed as a medium of

intercourse between the deaf and dumb, and blind persons; it is also commonly used by the former when they have to converse in the dark. As the art addresses itself to the sense of touch, as well as to that of sight, it is easy to touch another person's hands, who is acquainted with the hand-alphabet, in such parts or positions as to enable him to read the words or sentences thus conveyed. Bulwer, one of the earliest writers on the instruction of the deaf (vol. vi., p. 19), was fully aware of the advantage of manual alphabets in their instruction; and it seems strange that he did not invent one, or ascertain and make known the merits of one, of which he thus writes:—

'A pregnant example, of the officious nature of the touch, in supplying the defect or temporall incapacity of other senses, we have in one Master Babington, of Burntwood, in the county of Essex, an ingenious gentleman, who, through some sickness, becoming deaf, doth, notwithstanding, feele words, and, as if he had an eye in his finger, sees signes in the dark; whose wife discourseth very perfectly with him by a strange way of arthologie, or alphabet contrived on the joynts of his fingers; who, taking him by the hand in the night, can so discourse with him very exactly; for he feeling the joynts which she toucheth for letters, by them collected into words, very readily conceives what she would suggest to him.' (*Chirologia, or the Natural Language of the Hand*, p. 106.)

Perhaps the first manual alphabet which was published in England was that of Dalgarno, the most intelligent author on the subject of the instruction of the deaf and dumb next to Bulwer; he published it in 1680. As few copies of his work are now to be met with, we shall give his hand-alphabet, and accompany it by as much of his own explanation as seems necessary for understanding his views on dactylology. 'After much search and many changes, I have at last fixt upon a finger or hand-alphabet according to my mind; for I think it cannot be considerably mended, either by myself or any other (without making tinker's work), for the purposes for which I have intended it; that is, a distinct placing of and easy pointing to the single letters; with the like distinct and easy abbreviation of double and triple consonants.'

'The scheme (I think) is so distinct and plain in itself, that it needs not much explication, at least for the single letters, which are as distinct by their places as the middle and two extremes of a right line can make them. The rules of practice are two. 1. *Touch the places of the vowels with a cross touch with any finger of the right hand.* 2. *Poynt to the consonants with the thumb of the right hand.* This is all that I think to be needful for explaining the scheme, so far as concerns the single letters.'

This was probably the finger-alphabet from which our present two-handed one was derived; some similarities may be traced in them, particularly in the places for the vowels. The one-handed alphabet was invented in Spain, and appears to have been first published in Bonet's work. [BONET.]

A dactylology of syllables has been sometimes employed in the instruction of the deaf and dumb. This was one of the means adopted by Pereire, who lived in the middle of the eighteenth century, and who was more successful in imparting a knowledge of language to his pupils than any teacher who has since cultivated this difficult art. But his modes of teaching were a mystery which he always refused to divulge, and they were lost at his death. In our own days, M. Recoing has employed syllabic dactylology in conjunction with stenography, and by these means, combined with others more commonly pursued, he conducted the instruction of his own deaf and dumb son with that success which enabled him to convey to his son the words of a speaker as rapidly as they were uttered. M. Recoing published two works on this subject at Paris, in the years 1823 and 1829. A system of alphabetic and syllabic dactylology was also published by Dr. Deleau, the younger, in 1830.

There remains to be noticed another application of finger-language, which, in the instruction of the deaf and dumb, is next in importance to alphabetic signs; it is in the designation of numbers, and in the employment of the fingers in the first rules of arithmetic. The ten fingers are the most ready and natural abacus, as they are doubtless the most antient. That they should early come into use for exhibiting numbers, especially where speech was wanting, may be readily supposed. The only system of manual notation which deserves that name is the one which we shall now describe. It is used in several of the American and English institutions for the deaf and dumb; we consider it perfect, and we believe it has never before appeared in any English publication. Mr. David Seixas, of Philadelphia, improved the Abbé Sicard's signs for numbers, and his plan was used in the institution for the deaf and dumb in that city. The following system was invented by Mr. O. Stansbury, a former superintendent of the New York Institution; it has received a few, perhaps unimportant, modifications, and by it any amount of numbers may be expressed. One hand only, the left, is used, and the pupil's right hand is thus left at liberty to record his calculations upon his slate. The nine digits are represented one after another by elevating the fingers of the hand successively, thus:—

The cipher is represented by the closed hand.

The thumb represents *one*, the other fingers being closed, the index-finger is added for *two*, the middle-finger is raised for *three*, the ring-finger is added for *four*, and the open hand represents *five*; the little finger alone is raised for *six*, the ring-finger is added for *seven*, the middle-finger for *eight*, and the fore-finger is raised to the others for *nine*. Thus far for units. To indicate tens, the position of the hand is changed from perpendicular to horizontal; the thumb is pointed forwards for ten, the thumb and fore-finger for twenty, and so on to ninety. Hundreds are pointed downwards; thus the thumb, fore-finger, and middle-finger pointed downwards represent 300. If 572 be the number to be designated, three positions of the hand are required; the five fingers are pointed downwards for 500, the little-finger and ring-finger are pointed forwards for 70, and the thumb and fore-finger are held upright for two. During these changes the hand is kept in front of the body. To represent thousands, the left hand is placed across the body towards the right shoulder, and the signs which were used in front for units, in this situation, represent thousands; keeping the hand in the same situation and pointing forwards or downwards, tens of thousands or hundreds of thousands are exhibited. By changing the situation of the hand to the left shoulder, and by exhibiting the various positions of the fingers before described, millions, tens of millions, and hundreds of millions are expressed. The same positions, upright, forwards, and downwards, exhibited in other situations, may be applied to the expression of notations to any extent. Though rather complex in description, the whole is most easy and comprehensive in operation. The superiority of this system of manual notation for teaching arithmetic to the deaf and dumb, or for making signals of numbers where silence is necessary, compared with the clumsy resources of figuring the digits in the air, of repetitions of tens by the ten fingers, or even of arbitrary signs, will be at once acknowledged.

DACTYLO'PORA. [POLYPARIA MEMBRANACEA.]

DACTYLO'PTERUS (Lacépède), a genus of fishes of the order Acanthopterygii and family Loricati. Generic characters:—head flattened, large and long, and rising suddenly from the muzzle, which is very short; inferior angle of the pre-operculum furnished with an elongated strong spine; operculum without spines; mouth small; jaws furnished with masses of minute conical teeth; branchiostegous rays six in number; some of the anterior rays of the dorsal fin free; subpectoral rays numerous, very long, and connected by a membrane; ventral fins with four rays; body covered with hard carinated scales.

The fishes of this genus are classed with the gurnards; they may however be readily distinguished from the typical or true gurnards* by the immense size of the pectoral fins.

In the true gurnards we observe three detached rays situated under the pectoral fins, but springing from the same base: in our present genus these rays are very numerous, immensely long, and connected by a membrane. By means of these large fins, the length of which is almost equal to that of the body of the animal, these fishes are enabled to sustain themselves in the air for several seconds, which they often do to escape from their enemies when pursued; but in quitting the waters to avoid their pursuers in that element, they not unfrequently fall a prey to the frigate-birds and albatrosses.

This genus contains but two species, one of which has been long known: it inhabits the Mediterranean, and is the *Trigla volitans* of Linnæus, commonly called the flying-gurnard and flying-fish.† The other species inhabits the Indian Seas, and is the *Dactylopterus orientalis* of Cuvier.

* Those belonging to the genus *Trigla* as now restricted by Cuvier and others.

† There are other flying-fishes with which our present species must not be confounded. The common flying-fish belongs to the genus *Exocoetus*.

The flying-gurnard (*Dactylopterus volitans*) varies from one foot to fifteen inches in length, and is of a brown colour above, with spots of a deeper tint: the sides of the body are red, and the under parts are of a pale rose-colour. The large pectoral fins are of a blackish tint, mottled and spotted with blue; the ventral and anal fins are of a rose-colour; the anterior dorsal is gray, with clouded markings of a deeper hue; the posterior dorsal is transparent, and its rays are of a pale colour, spotted with brown.

[*Dactylopterus orientalis*.]

DADO, a term for the die or plane face of a pedestal. The dado employed in the interiors of buildings is a continuous pedestal, with a plinth and base moulding and a cornice or dado moulding surmounting the die. This continuous pedestal, with its moulding, is constructed of wood, and is usually about the height of a chair-back. Its present use is to protect the stucco-work or paper of the walls, but originally it was used as an architectural decoration to a room. The construction requires care in joining the deals of the dado, which are ploughed and tongued and keyed transversely at their backs, in order to prevent any joint from appearing in the die or plane surface. Some dados are pannelled.

DÆDA'LION. [FALCONIDÆ.]

DAFFODIL, the English name of *Narcissus Pseudo-Narcissus* and its allies, to which some recent botanists have given the generic name of *Ajax*.

DAGHESTAN, a country situated on the western shores of the Caspian Sea, extending from the mouth of the river Terek, 43° 50' N. lat., to the peninsula of Absheran on the south, 40° 30' N. lat. Though forming a part of the Russian government of Georgia, the different tribes which inhabit the valleys on the eastern declivities of Mount Caucasus are governed by independent petty sovereigns, but those which possess the low and hilly country towards the sea are dependent on the Russian governor. The term Daghestan means the mountainous country, from the Turkish word *Dagh*, a mountain. [GEORGIA and DERBEND.]

DAGHO, **DAGOE**, or **DAGEN**, an island at the entrance of the gulf of Finland, about 41 miles long, and varying from 27 to 37 miles in breadth; in 58° 4' to 59° N. lat., and from 22° 20' to 23° 8' E. long. It is comprehended in the Russian province of Reval, circle of Habsel, and is divided by a small channel from the island of Oesel. Its area is about 304 square miles: it contains three parishes. The inhabitants, about 10,000 in number, are Esthonians; they are employed in husbandry, grazing, fisheries, and carry on a little trade in the port of Tewenhaven, which lies on the eastern side of the island. The coasts abounding in shallows and sandbanks, a lighthouse has been erected near the village of Dagerort, in 58° 50' N. lat., and 22° 40' E. long. The Swedes, to whom the Danes ceded Dagho in 1645, ceded it in their turn to Russia under the treaty of Nystadt, in 1791.

DAGOBÉ'RT I., son of Clotarius II., succeeded him in 628 in the Frankish monarchy. He gave his brother Caribert a part of Aquitania, with the city of Toulouse, but Caribert dying in 630, Dagobert reunited the whole monarchy under his sceptre, and caused Chilperic, Caribert's eldest son, to be put to death. Boggis, another son of Caribert, was the head of the line of the dukes of Aquitaine, and of the counts of Armagnac. Dagobert sustained wars against the Saxons from England, the Vascones of the Pyrenees,

the Slavonians, and the Bretons, and he obliged Judicaël, the prince of Brittany, to give him satisfaction for the incursions which he had made into his territories. When the Bulgarians were flying from before the Huns, they took refuge in Austrasia, where Dagobert granted them an asylum; but soon after, fearing that these guests might become too powerful for him, he gave orders to have them all massacred in one night, when 10,000 families were put to the sword. Dagobert was cruel and debauched, like all the rest of the Merovingian kings; and yet in the old ballads and chronicles he is called 'le bon Roi Dagobert.' He published the laws of the Franks; he encouraged commerce, and opened negotiations for that purpose with the Byzantine emperors; and he made Paris his permanent residence. The wealth and splendour of his court are extolled by the chroniclers. Eligius, or Eloi, a skilful goldsmith of the time, became his treasurer and confidential minister, and was also made bishop of Noyon. Dagobert died in 638, in his thirty-sixth year, and left two sons, Siegbert II., who succeeded him in Austrasia, and Clovis II., who became king of Burgundy and Neustria.

DAGOBERT II., son of Siegbert II., king of Austrasia, was shut up in a convent after his father's death, in 656, by Grimoald, maire of the palace, who gave the crown to his own son. Dagobert was sent to Scotland, and the report of his death was spread in France. In Scotland he married Mathilda, a Scotch princess, and after many years returned, and was acknowledged king of Austrasia. He was murdered in 679 by Ebroïn, maire of the palace of Thierry III., king of Burgundy and Neustria. Pepin d'Heristel succeeded Dagobert in Austrasia, not as king, but with the title of duke.

DAGOBERT III. succeeded his father Childebert III. as king of the Franks in 711. Pepin d'Heristel continued to enjoy the whole authority, as he had done under the preceding reigns, owing to which circumstance the nominal kings have been styled in history Rois Fainéans. Pepin died in 714, and Rainfroy succeeded as maire of the palace. In 715 Dagobert died, leaving a child called Thierry, who was afterwards called Thierry IV., and was set up as a nominal king by Charles Martel, the natural son of Pepin d'Heristel. (Henschenius, *Historical Dissertation on the three Dagoberts*, 4to., 1653.)

DA'GYSA. [SALPA.]

DA'HLIA, a small genus of Composite flowers, of which three species only are known, all natives of Mexico. Of these, two, *D. coccinea* and *D. Cervantesii*, were formerly cultivated in this country, but not sporting into varieties, and being much less beautiful than *D. variabilis*, they are not now seen in gardens. *D. variabilis* itself is, in its wild state, a bushy herbaceous plant, seven or eight feet high, with single purple or lilac flowers, and is by no means remarkable for its beauty. In cultivation however it is so readily improved in size and form, and sports into such endless varieties in stature, leaves, and flowers, that it has become the most extensively cultivated florist's plant of the present day. Its innumerable sorts are the glory of our gardens in the autumn, and are quite unrivalled at that season of the year: they are however destroyed by the earliest frosts. Each season produces its favourite varieties, and these are in their turn eclipsed by others of a newer or a choicer form. For those which are the most in vogue at the present day the nurserymen's lists should be consulted; their fleeting reputation renders them undeserving of notice in a permanent work.

As some attempts have been made of late years to substitute the name of Georgina for that of Dahlia, we may take this opportunity of stating that the name Dahlia originated with the Spanish botanist Cavanilles in 1791; that the name was applied by Thunberg to a different genus in 1792, without however superseding the former; that the name Georgina was not heard of till 1803, and that consequently, as priority of publication settles all such matters, there is no pretence for abolishing Dahlia and substituting Georgina.

DAHOMY, a celebrated and for some time powerful negro kingdom of western Africa, lying inland from the part of the coast of Guinea called the Slave Coast. It is bounded on the west by Ashantee, from which it is divided by the river Volta. Its southern boundary is about sixty or seventy miles from the sea, and it is supposed to extend about 150 or 200 miles farther into the interior, which would bring it near the range of the Kong Mountains. Its

capital, Abomey, is placed in lat. $7^{\circ} 59' N.$, and in about long. $3^{\circ} 20' E.$

Even the name of Dahomy may almost be said to have been unknown in Europe till some time after the beginning of the last century. Dauma, which is no doubt the same kingdom, is indeed mentioned by Leo Africanus, along with several others, of which he merely says that they lie south of Nigritia; and that name is found placed where Dahomy lies in several maps published towards the end of the sixteenth century, the earliest being probably one in the Geography of Sanutus, published at Venice in 1588. It occurs so placed even in the Maps of Sir Jonas Moore's Mathematics, published under the care of Dr. Halley in 1681; but in another map published by Halley in 1700 it is omitted, and it does not again appear for a considerable time. The most recent accounts indeed now represented the whole of that part of Africa as occupied by other states. Bosman, who has minutely described this part of the African coast from personal observation, in a series of letters written in 1700 and 1701, makes no mention of Dahomy. The Dahomans for the first time made their appearance on the coast where the European establishments were in the reign of their king Trudo Andati, or, as other accounts call him, Guadja Trudo, who is said to have succeeded to the throne in 1708. This prince, who appears to have been a person of remarkable talent, as well as of inordinate ambition and warlike ferocity, having determined upon securing to himself a share of the European commerce, in forcing his way to the coast captured in 1724 the chief town of the kingdom of Ardra, the most powerful state that lay between him and the sea. Here he found a Mr. Bulstrode Lamb, who resided in the place as factor for the English African Company. Lamb was detained in captivity for nearly three years; but was treated with extraordinary kindness and consideration by the black monarch, who till now had never set his eye upon either a white man or the sea. We believe the earliest account of Dahomy that exists is a very curious letter written by Lamb, after he had been for some months in captivity, to his superior, Mr. Tucker, governor of the English fort at Whidah (the Juida of the French, and Fida of the Dutch). It is dated from Abomey, in November, 1724; but did not appear in print till it was published at the end of a 'New Voyage to Guinea,' by William Smith, Esq., which appeared at London in 1745. Smith had been on the Slave Coast in the beginning of March, 1727, when he found that only a few days before his arrival the king of Dahomy had effected the conquest of the state of Whidah, lying along the coast, and had laid in ruins the English, French, and Portuguese forts situated at its capital, Sabi, or, as the French call it, Xavier. The captains of these forts and all the European residents were now prisoners in the Dahoman camp. However, they were all soon after released, as Lamb had been a short time before. We have the continuation of the narrative in the 'Full Account of some part of Guinea,' published at London, in 1734, by Captain William Snelgrave, who arrived at this part of the African coast only a few weeks after Smith, and while the king of Dahomy and his troops still occupied the territory. The narrative of Snelgrave, who visited the Dahoman camp, is exceedingly curious. In 1729 he made a second voyage to the same coast. In the interval the king of Dahomy and the governors of the French and English forts had again come into collision; and just before Snelgrave's arrival, Mr. Testefole, the English governor, who had imprudently endeavoured to excite the people of Whidah to an insurrection against their Dahoman masters, had been seized by the latter and put to death. Snelgrave has, from the information of others, brought down his account to the end of March, 1732, at which time a new quarrel had ended in the destruction of the Dutch, English, French, and Portuguese forts at the town of Jaquin, the only other part of the Slave Coast where there were any European establishments. The residents, however, although taken prisoners in the first instance, were all eventually allowed to take their departure. It is asserted, nevertheless, that Guadja Trudo in his advanced years became more blood-thirsty than ever, and that a morbid suspiciousness by degrees took possession of him, and destroyed the better qualities of his former character. He died this same year, and was succeeded by his son, Bossa Ahadee. A work entitled 'Memoirs of the Reign of Bossa Ahadee, with an Account of a Journey to Abomey in 1772,' was published in 1789, by Mr. Robert Norris of

Liverpool, a person who had been engaged for eighteen years in the African trade. It is accompanied by a map of the kingdom of Dahomy, and is reprinted, with many corrections and additions by the author, in 'The History of Dahomy, compiled from authentic memoirs, by Archibald Dalzel, Esq., governor of Cape Coast Castle,' 4to., London, 1793. This last-mentioned work brings down the history of Dahomy, through the reigns of Ahadee, a detestable tyrant, the scourge of his own subjects and the torment of all his neighbours, for forty years; of his son, Adahoonzou II., by whom he was succeeded in 1774, and who continued his oppression and his ferocious wars; and of the first years of that of Adahoonzou's son and successor Wheenooheh, who mounted the throne in 1789. The materials for the two last reigns were contributed by Lionel Abson, Esq., the British governor at Whidah, who had then been twenty-seven years in the country. The continuation of the history of Dahomy for some years further is given in a little work entitled 'A Voyage to Africa, with some account of the Manners and Customs of the Dahomian People,' by John M'Leod, M.D., 12mo., London, 1820. Mr. M'Leod visited this part of Africa in 1803. At that time Dahomy still seems to have been a powerful state, and to have exercised sovereignty over all that part of the coast of Guinea. The reigning king was a younger son of Wheenooheh, the elder having been set aside because one of his toes overlapped another. It appears, however, from the accounts of Clapperton and the Landers, that Dahomy has now been reduced to subjection by the neighbouring state of Yarriba; and it is probable that Yarriba in its turn very soon will be, if it has not already been, absorbed by the extending empire of the Fellatahs.

The region in which the kingdom of Dahomy is situated is a vast plain rising by a very gentle ascent from the sea. No river worth notice falls into the sea between the Volta and the Brass river, or Niger. The soil is a rich reddish clay, on which scarcely a stone is to be found of the bigness of a walnut. All who have visited the coast, especially before the devastations of the Dahomans, describe it as a scene of matchless beauty and luxuriance. An ample account of its vegetable productions, comprising maize and other farinaceous crops; yams, potatoes, pine-apples, melons, oranges, limes, guavas, and other tropical fruits; a singular fruit said to possess the property of communicating a sweet taste to the strongest acids and bitters; indigo, cotton, sugar, tobacco, palm oil, spices, &c., may be found in the introduction to Mr. Dalzel's book, to which may be added some notices in Mr. M'Leod's volume. The country abounds with tigers, leopards, hyænas, elephants, buffaloes, deer, sheep, goats, hogs, both wild and tame, and several varieties of poultry. It is also infested by boa snakes of immense size, and other kinds of serpents. The government of Dahomy is, or at least formerly was, as absolute a despotism as has anywhere existed; and authority is maintained by the shedding of blood at a rate which has been approached nowhere but in Africa. The customs or festivities held at the court of the monarch on occasion of the annual receipt of duties or tribute, are of the same ferociously sanguinary character with those that take place at Ashantee. Their regular season appears to be in April or May, but instances are mentioned of their lasting for three months, and in these cases they seem to begin earlier in the year. The chief ornament of the royal residence is human skulls, of which, when a number was wanted to pave a court or decorate a ceiling, it was not an unusual process to have some scores of persons massacred for the purpose. The principal trade formerly carried on with Dahomy and the subject states on the coast was in slaves; and since the abandonment of that trade on the part of the principal European powers, which used to resort to this part of Africa, the commercial intercourse which these kingdoms hold with other parts of the world has become quite insignificant. The only money of the Dahomans consists of cowry shells, of which a thousand are stated to represent half-a-crown English. Their language is the same with that of the people of Whidah and the other nations of the coast.

DAILLE', JEAN, was born at Chatelleraut in 1594, of a Protestant family. In 1612 he undertook the education of the two grandsons of Duplessis Mornay, the friend of Henry IV., and he travelled with them in several countries of Europe. At Venice he became acquainted with the famous Fra Paolo Sarpi. On his return to France he became pastor at Charenton in 1626. He published many

works on divinity, both in Latin and French, and especially on controversial subjects. He was one of the most learned and most powerful advocates of the Protestant doctrines in his time. His principal productions are:—1, 'Traité de l'emploi des S. S. Pères pour le jugement des différends de la religion,' Geneva, 1632, which was also published in Latin, with the title 'De usu Patrum:' it is one of Daillé's best works, and much esteemed, especially by the Presbyterians; 2, 'De la croyance des Pères sur le fait des images;' 3, 'Adversus Latinorum traditionem de religiosi cultus objecto;' 4, 'De cultibus religiosi Latinorum.' These three last works attempt to prove, that in the early or primitive Christian church there was no religious worship paid to the host, nor to relics, cross, images, &c. 5, 'De confirmatione et extrema unctione;' 6, 'De sacramentali sive auriculari Latinorum Confessione,' Geneva, 1661. This last work puts forth the strongest arguments against the practice of auricular or private confession. [CONFESSION.] 7, 'De scriptis quæ sub Dionysii Areopagitæ et Sancti Ignatii Antiocheni nominibus circumferuntur,' Geneva, 1666. Daillé looks upon the works attributed to Dionysius and Ignatius, of Antioch, as apocryphal. This, which is a work of much historical and critical learning, is dedicated to Samuel Bochart. 8, 'De pænis et satisfactionibus humanis.' He also wrote an apology of the reformed churches and numerous sermons, which have been collected in several volumes, and also 'Dernières heures de Duplessis Mornay,' Leyden, 1647. Daillé died at Paris in 1670. His son, Adrien Daillé, left France at the revocation of the Edict de Nantes, and retired to Zürich, where he wrote his father's life.

DAIRY, the name usually given to the place where the milk of cows is kept and converted into butter or cheese. The occupation is called *dairying*; and land which is chiefly appropriated to feed cows for this purpose is called a *dairy-farm*.

A dairy-house should be situated on a dry spot somewhat elevated, on the side of a gentle declivity, and on a porous soil. It should be on the west or north-west side of a hill if possible, or at least sheltered from the north, east, and south, by high trees. In some countries where there are natural caverns with an opening to the west, and springs of water at hand, the best and coolest dairies are thus prepared by nature. Artificial excavations in the sides of free-stone rocks are sometimes formed for the purpose of keeping milk, and more frequently wine. Where no such natural advantages exist, the requisite coolness in summer, and equal temperature in winter, which are essential in a good dairy, may be obtained by sinking the floor of the dairy some feet under ground, and forming an arched roof of stone or brick. In cold climates flues around the dairy are a great advantage in winter; and an ice-house in warm summers is equally useful. But these are only adapted to those dairies which are kept more as a luxury than as an object of profit. In mountainous countries, such as Switzerland, where the summers are hot in the valleys, and the tops of the mountains or high valleys between them are covered with fine pastures, the whole establishment of the dairy is removed to a higher and cooler atmosphere, where the best butter and cheese are made. Coolness is also produced by the evaporation of water, an abundant supply of which is essential to every dairy. It is also a great advantage if a pure stream can be made to pass through the dairy, with a current of air to carry off any effluvia, and keep the air continually renewed.

As the milk suffers more or less from being agitated, or too much cooled, before it is set for the cream to rise, the cow-house or milking-place should be as near as possible to the dairy, or rather it should be under the same roof. The milk may then be brought immediately from the cows, without being exposed to the outer air. The dairy-house should consist of three distinct apartments below, with lofts and cheese-chambers above. The principal place is the dairy, properly so called, sunk two or three feet below the level of the ground, with a stone or brick bench or table round three sides of it to hold the milk pans. This table should be a little below the level of the outer soil. Air-holes covered with wire should be made in the walls a little above, and on opposite sides of the dairy; and they should have shutters sliding over them to open or shut according to the weather. The floor should be of stone or paying tiles, sloping gently towards a drain to carry off the water. Great care should be taken that no water stagnates

in this drain, which must be kept as clean as the floor of the dairy, and not communicate with any sink, but run out into the open air: a declivity from the dairy is essential for this purpose. If this cannot be obtained, it must run into an open tank, and the water be regularly pumped out. The windows of the dairy should be latticed. Glazed windows may be added for the winter, but they should always be open except in very hot or very cold weather. There may be shutters to close entirely, but this is not essential. If the windows are made like venetian blinds, the light will be excluded without excluding the air. The utmost purity must be maintained in the air of a dairy; nothing should enter it that can produce the slightest smell. No cheese or rennet should be kept in it; and particularly no meat, dressed or undressed. Even the dairy-maid should avoid remaining longer in it than is necessary, and should at all times be extremely clean in her person.

The next important place is a kind of wash-house, in which there is a chimney where a large copper kettle hangs on a crane to heat water in, or milk when cheese is made. In countries where wood is scarce, and pit-coal is the common fuel, a copper may be set in brick-work with a grate under it, as is usual in England. In this place all the utensils of the dairy are kept, and scalded with boiling water every day. It should have an outer door, which may be to the south, and benches outside on which the pails and other utensils may be set to dry and be exposed to the air. Between the two last apartments may be another communicating with both, and forming a kind of vestibule, where the churning may take place; and over them a cheese-room and lofts, or any other useful chambers. A verandah round the dairy is very convenient, or on three sides at least. It shades from the sun, and adds to the warmth in winter; and the utensils may be dried and aired under it even in rainy weather. Gentlemen's dairies are often built expensively, and highly ornamented; but they seldom unite all the conveniences essential to a good dairy, because the architects who plan them are seldom practical farmers. They are generally too far from the cow-houses, which might be joined to them without detracting from the neatness of the structure. A dairy-house placed near a mansion, and at a distance from the farm buildings, is quite out of its place. In Switzerland and in Holland, the cow-house and dairy often have a very neat appearance within a short distance from the principal residence. The plan in both countries is very similar; the style of the roof is the chief difference. It is taken from the common dairy-farms in Holland, where the farmer and his family live under the same roof with his cows. In the Netherlands, especially in North Holland and Friesland, a cow-house is as clean as any dwelling-house, and the family often assemble and take their meals in it. The following description of a cow-house and dairy under one roof combines all that is useful, with considerable neatness internally and externally:—It is a building about sixty feet long by thirty wide, with a verandah running round three sides of it. The dwelling is not here attached, as it usually is in common dairies, and the building is not surrounded by a farm-yard: these are the only circumstances in which it differs from that of a common peasant. The dairy-room is sunk below the level of the soil, and is paved with brick. The sides are covered with Dutch tiles, and the arched roof with hard cement. The cow-house, like all in Holland, has a broad passage in the middle, and the cows stand with their heads towards this passage, which is paved with clinkers or bricks set on edge. Their tails are towards the wall, along which runs a broad gutter sunk six or eight inches below the level of the place on which the cows stand. This gutter slopes towards a sink covered with an iron grate, which communicates by a broad arched drain with a vaulted tank into which all the liquid flows. The gutter is washed clean twice a day before the cows are milked. The cows stand or lie on a sloping brick floor, and have but a small quantity of litter allowed them, which is removed every day and carried to the dung-heap or to the pig-styes to be more fully converted into dung. Whenever the litter is removed, the bricks are swept clean; and in summer they are washed with water. In Holland the cows' tails are kept up by a cord tied to the end of them, which passes over a pulley with a weight at the other end, as we see practised with horses that have been nicked: thus they cannot hit themselves, or the person who milks them. The manner in which the cows are fastened is worthy of notice:—Two slight pillars of strong wood

are placed perpendicularly about two feet distance from each other, so that the cow can readily pass her head between them. On each of these is an iron ring, which runs freely up and down, and has a hook in its circumference: two small chains pass from these hooks to a leather strap, which buckles round the neck of the cow. Thus the cow can rise, and lie down, and move forward to take her food, which is placed in a low manger before the two pillars; but she cannot strike her neighbour with her horns. The mangers or troughs are of wood, or of bricks cemented together, and are kept as clean as all the rest of the cow-house. In

Side view.

Section of the Cow-house.

Section of the Dairy.

Ground Plan.

A, A, A, passage through the cow-house and dairy ten feet wide, paved with bricks set on edge or Dutch clinkers. The food is brought in this passage in a small cart and distributed to the cows.

B, part of the above passage closed in with doors and forming a vestibule to the dairy; C, dairy-room, in which only milk, cream, and butter, are kept. It is sunk three feet under the level of the cow-house, and covered with a brick arch; it has one latticed window, and several ventilators, on a level with the place on which the milk vessels are set.

D, the room where the utensils are scalded, and where cheese is made; in one corner is a fireplace, with a large kettle or a copper set.

E, a stairs to go up to the cheese-room M, and loft N.

F, calf-pens, in which the calves are tied up to fatten, so that they cannot turn to lick themselves; a small trough with pounded chalk and salt in each pen.

G, the place for the cows, without partitions; each cow is tied to two posts by two small chains and two iron rings, which run on the posts. The chains are fastened to a broad leather strap, which is buckled round the neck of each cow. H, H, two sinks, with iron gratings over them, to catch the urine from the gutters I, I, which run all the length of the cow-house on each side. K, the urine tank, vaulted over with a door, L, to clean it out, and a pump to pump up the liquid manure. O, O, in the section, are places where the green food or roots are deposited for the day's consumption. P, a hay-loft.

Switzerland the cow-houses are similar, but there is also a rack, the back of which towards the passage shuts up with a board on hinges. The Dutch mode supplies more light and air to the middle passage; and as the food is given frequently and in small quantities there is very little waste. The preceding cuts will give a tolerable idea of the whole arrangement. The food is brought in carts, which are driven at once between the cows. What is not wanted immediately is stored above, whence it is readily thrown down before the cows. Thus much trouble is saved, and one man can feed and attend to a great many cows. From November till May the cows never leave the cow-house. In summer when they are out, if they are in adjacent pastures, they are driven home to be milked, but if the pastures are far off, which is sometimes the case, they are milked there, and the milk is brought home in boats; but this is not thought so good for the butter, which is then always churned from the whole milk, without letting the cream rise. The finest and best flavoured butter is always made from the cream as fresh as possible; and to make it rise well, the milk should be set as soon as it is milked, and agitated as little as possible. The greatest quantity is seldom obtained when the quality is the finest. When great attention is paid to the quality, the milk is skimmed about six hours after it is set; and the cream taken off is churned by itself. The next skimming makes inferior butter. These particulars are mentioned to show the necessity there is of having the dairy as near as possible to the cow-house.

The utensils of the dairy, such as pails, churns, vats, &c., are usually made of white wood, and are easily kept clean by scalding and scouring. Leaden troughs are used in large dairies; and if they are kept very clean by careful scouring, they answer the purpose better than wood. They may be so constructed that the milk may be let off gently before the cream, which is collected by itself. This saves all the trouble of skimming. Brass pans have the advantage of being readily warmed on a chafing dish in winter. In Devonshire tin or brass pans are frequently used instead of earthenware. Although there is some danger in the use of brass utensils, very little attention will obviate it. It only requires that they should be kept bright, in which case the smallest speck of oxide or verdigris would be perceptible. In Holland the milk is invariably carried in brass vessels. Cast-iron pans have been invented, which are tinned inside. They are economical; but there is nothing better or neater than well-glazed white crockery ware, of the common oval form. Some recommend unglazed pans for summer, but they are difficult to keep sweet, as the milk insinuates itself into the pores, and is apt to become sour there.

The most common use of cows is to supply butter and cheese [BUTTER and CHEESE], and sometimes to fatten calves [CALF] for the butcher; but the most profitable dairy is that which supplies large towns with milk. In these dairies the system is different. The cows are mostly kept in stalls, and fed with food brought to them. Some dairymen near London possess several hundred cows, and the arrangement of their establishments is worthy of notice. The cows are bought chiefly in the north, before or after they have calved. They are seldom allowed to go to the bull, but are kept as long as they can be made to give milk by good feeding. When they are dry, they are often already sufficiently fat for sale, or at all events they soon fatten, and are sold to the butcher. A succession of cows is thus kept up, new ones arriving as others are sold off. The women who purchase the milk from the dairyman and carry it about for sale, come for it to the dairy and milk the cows twice a day; and as they well know that the last drop of milk is the richest, the cows are sure to be milked quite dry, an essential thing in a dairy. An accurate account is kept of the quantity which each woman takes, which is paid for weekly. When there is more milk than there is a demand for, it is set, and the cream is sold separately, or made into butter; but this is seldom done to any extent. The cows are fed on every kind of food that can increase the milk: brewers' grains and distillers' wash are preferred, when they can be obtained. The grains are kept in large pits, pressed close and covered with earth, under which circumstances they will remain fresh a long time. Turnips and beet-root are used in large quantities; but hay is given sparingly. The cows are generally placed in pairs, with a partition between every two pair. Each cow is fastened to the corner of the stall, where she has a small trough with water before her: thus

they cannot gore each other with their horns. The great dairies about London are kept very clean; but the liquid manure, which would be so valuable for the market-gardens, is lost, and runs off by the sewers. In Belgium the urine would be contracted for at the rate of 2*l.* per cow per annum, which would produce 1200*l.* a year in a dairy of 600 cows, and would pay a good interest for the money expended in constructing large vaulted cisterns under each cow-house.

The dairy farms of England are chiefly in Gloucestershire, Devonshire, and Cheshire. They require a smaller capital than arable farms of the same extent; the chief outlay is the purchase of cows. The rent of good grass land is generally higher than if it were converted to arable land; and the risk from seasons, and from a variation in the price of the produce, is much less in a dairy farm than in one where corn is chiefly cultivated. Hence the rents are better paid, and there are fewer failures among the tenants: but the profits of a dairy farm, without any arable land, are not considerable; a decent livelihood for the farmer and his family is all that can be expected. There is no chance of profit in a dairy of which the farmer or his wife are not the immediate managers. The attention required to minute particulars can only be expected in those whose profit depends upon it. The dairies of men of fortune may be arranged on the best and most convenient plan, and be indispensable articles of luxury; but the produce consumed has always cost much more than it could be purchased for. A proper attention to keeping correct accounts of every expense will convince any one of this truth. In a dairy farm the great difficulty is to feed the cows in winter. It is usually so arranged, that the cows shall be dry at the time when food is most scarce, and they are then kept on inferior hay, or straw, if it can be procured. It is a great improvement in a dairy farm if it has as much arable land attached to it as will employ one plough, especially if the soil be light; but the mode of cultivating this farm must vary from that of other farms, since the food raised for the cows must be a principal object. Corn is a secondary object; and the cultivation of roots and grasses must occupy a great portion of the farm. When the grasses degenerate, a crop or two of corn is taken, and the rotation is chiefly roots, corn, and grass cut for hay, until it wears out. If the roots are well manured, the land keeps in excellent heart. The old pastures are kept for summer feeding. Where there is no arable land near a dairy farm, it deserves mature consideration whether it will be advantageous or not to allow some of the pasture to be ploughed up. It is often a dangerous experiment where the soil is naturally heavy, which is the case with most dairy farms in England. Arable land laid down to grass for the purpose of the dairy seldom produces fine-flavoured butter, or good cheese; but clover-hay is excellent for young stock, or to fatten off the old cows. Lucern is reckoned to make cows give very good milk: nothing however can equal a rich old pasture, as all dairymen agree.

In hiring a dairy farm, it is an object of great importance that the buildings be situated near the centre of the land, and that they be well constructed and convenient. The nature of the feed must be ascertained by experience. It is often impossible to say by mere inspection whether a pasture will make good butter or cheese, especially the latter. But those which have no great reputation may often be highly improved by draining, and also by weeding, a thing too much neglected in pastures.

DAIS or DEIS, a word which occurs very frequently in old English authors; as in Chaucer, Prologue to the Canterbury Tales, v. 372.

Wel semed eche of hem a fayre burgeis,
To sitten in a gilde halle, on the *deis*.

Tyrwhitt apprehends that it originally signified the wooden floor (Fr. *d'ais*, Lat. *de assibus*) which was laid at the upper end of the hall, as we still see it in college-halls, and in most, if not all, of those of the city companies in London, and those belonging to the inns of court. That part of the room being floored with planks was called the *deis*, the rest being either the bare ground, or, at best, paved with stone; and being raised above the level of the other parts, it was called the *high deis*. In royal halls there were more *deises* than one. Christine of Pisa (Hist. Cha. V., P. iii., c. 33) says that at a dinner which Charles V. of France gave to the emperor Charles IV. in 1377, there were *five deis*.

As the principal table was always placed upon a *deis*, it

began, by a natural abuse of words, to be called itself a deis, and people were said to sit *at the deis* instead of *at the table upon the deis*. So in 'Matthew Paris,' *Vit. Ab.*, p. 1070, 'Priore prandente ad magnam mensam, quam deis vocamus?'

Menage, whose authority has led later antiquaries to interpret *deis* a canopy, has evidently confounded *deis* with *ders*.

(Ducange, *Glossary*; Tyrwhitt's *Notes on Chaucer's Canterbury Tales*, 4to., Oxford, 1798, vol. ii., p. 403.)

DAISY, or DAY'S EYE, the little perennial plant called *Bellis perennis* by botanists. Like most composite flowers, it has proved productive of varieties when domesticated; but they have almost disappeared, except from old-fashioned or cottage gardens. And yet the varieties are in some cases very pretty, and well suited for an edging to borders. The double-red, the striped, and the hen-and-chickens are the prettiest sorts. The latter is a curious permanent vegetable monster, and derives its singular name from each of the flower-heads being surrounded by a quantity of smaller heads half covered by the mother-head, as a brood of chickens is by the wings of the hen. This circumstance arises from the leaves or leaflets of the involucre generating buds from their axils, instead of remaining sterile, as such leaves usually are.

DALAGO'A BAY is situated on the eastern coast of Southern Africa, where the twenty-sixth parallel and the thirty-third meridian intersect one another. It is a large bight, extending about twenty miles east and west, from Cape Ingack to the entrance of the English River; twenty-two miles to the southward of this line it affords good anchorage for the largest vessels, and will probably some time be an important place, as there does not exist between it and False Bay, near Cape Town, any port in which a vessel drawing more than eight feet of water can enter, though this line of coast is upwards of 1000 miles in length. Three rivers enter the bay; the Manice or King George's River, the English River, and the Mapoota, and they are all navigable for a considerable distance. The English River is properly an æstuary, into which three other rivers discharge themselves, at the distance of eight miles from the bay. On this æstuary, about two miles from the sea, is built a Portuguese fort, the most southern possessed by that nation in Africa; but it is a miserable place, consisting of three or four houses: its garrison is composed of three officers and about fifty Mozambique black soldiers, with a governor. The fort contains only a few rusty cannons.

The country near the shores of the bay is low, marshy, and unhealthy; but at no great distance from it the ground rises, is healthy, well peopled, and comparatively well cultivated. It is inhabited by three or four tribes, independent on each other. (London, *Geographical Journal*, iii.; and Threlfall, in Bannister's *Humane Policy, or Justice to the Aborigines*, &c.)

DALAI LAMA. In the article BUDDHA it is noticed, as an essential point in the faith of the Buddhists, that on the death of the founder of their sect, his soul became immediately re-embodied in the person of another religious chief of the Buddhist community, and that in this manner the same Buddha continued to reappear among his followers in a succession of spiritual rulers, who have by some writers very appropriately been called Buddhist patriarchs. From the time when the last of these patriarchs quitted India and took his abode in China (*i. e.*, towards the close of the fifth century of our æra), we hear of more than one spiritual chief, subordinate to the patriarch, appearing at the same time in the several countries in which Buddhism has become the prevailing religion. Chinese historians make mention of them under the honorific appellations of Preceptor of the Kingdom, Prince of the Faith. It seems at an early age to have become a matter of policy with the secular sovereigns of Buddhist countries to attach these religious chiefs to their interests; and thus was laid the foundation of an hierarchical system, which subsequently developed itself to an extent without a parallel in history. For eight centuries the Princes of the Faith continued in comparative obscurity at the courts of Buddhist sovereigns; and it was not till the thirteenth century that the chief residing at Putala, in Tibet, was by the victories of the Mogols, under Genkis khan and his successors, raised to the rank of supreme pontiff of the sect. A separate province in Tibet was assigned to him as his own territory; and besides his spiritual dignity he became, to a

limited extent, a temporal monarch. The Tartars, who in the fourteenth century put an end to the Mogol power in Tibet, paid even greater deference to the Buddhist pontiff. Eight subordinate chiefs, or rather as many inferior incarnations, were appointed to act as his council; and titles expressive of his transcendent power and authority in spiritual matters were conferred upon him. The word Lama, which properly signifies a priest, became from that time an illustrious appellation. The title Dalai Lama, *i. e.*, 'The Priest who resembles the ocean (in greatness of mind),' has been applied to the pontiff since the beginning of the sixteenth century. Occasions for jealousy and contention between the pontiff and the other spiritual chiefs, who resided in various parts of Chinese Tartary, could not be long wanting; and we find that the Tartar princes, among whom the possession of Tibet and the neighbouring countries was at different times contested, availed themselves of these dissensions for the advancement of their own interests. With all their professed veneration for the spiritual character of the Dalai Lama, we hear of more than one instance of his being deprived of his dignity and even of his life. Such the condition of the Tibetan hierarchs seems to have remained till within recent times. The predecessor of the Lama, to whom Turner was sent as ambassador from the Bengal government, had been invited to visit the emperor of China, and died soon after his arrival at Pekin (in 1780), under circumstances which justified the suspicion of his having been poisoned. [LAMAS.] (A. Rémusat, *Mélanges Asiatiques*, vol. i. p. 129—145.)

DALECARLIA, properly DALARNE (the valley country), a province of Sweden, extends from 60° 55' to 62° 12' N. lat., and from 12° 30' to 16° 40' E. long. Its surface is 12,225 square miles, or more than twice the area of Yorkshire. On the north it borders on Herjedalen, on the east on Gertrikland, on the south on Westmanland, Nerike, and Vermland, and on the west on Norway.

The mountain-ridge, which divides the sources of the two rivers Dalelf from Lake Fämund in Norway, rises to between 3000 and 4000 feet above the sea. It is a southern offset of the Kölen (pronounced Tioelen) range, and from it there branch off three ridges of considerable elevation. The most northern separates the river Ljusnaelf from the Oester Dalelf; the middle, the Oester Dalelf from the Wäster Dalelf; and the southern runs between the Wäster Dalelf and the Klarelf. These ranges subside into hills before they reach the meridian of the Lake of Silian. The country about this lake presents a pleasant intermixture of hills, valleys, and plains, and may be compared to the lower parts of Switzerland for scenery. But the whole country still preserves a considerable elevation, the surface of Lake Silian being about 560 feet above the sea. The eastern districts are also uneven, but the heights are rather round-backed hills than mountains, and are usually covered with wood. Numerous lakes of different size lie between them. It is only on the borders of Gestrikland that plains of any extent occur.

Like the other parts of Sweden, Dalecarlia abounds with rivers and lakes. The principal river is the Dalelf, which originates in two powerful branches on the mountain-range forming the western boundary. The Oester Dalelf runs south-east, and after traversing the Lake Silian unites with the Wäster Dalelf, which originates a little farther south, and in the beginning is called Fuluef. It runs south-south-east, but near Apelbo it turns suddenly to the east, and continues in that direction to its junction with the Oesterelf. The united river Dalelf runs south-east to Avestad, and hence north-east to its entrance into the Gulf of Bothnia. About six or seven miles from its mouth it forms the cataract of Elfcarleby, the rival of the famous cataract of Schaffhausen in height and beauty. The Lake Silian is from twenty-seven to twenty-eight miles long, and fifteen broad, where widest. It contains several fine islands, on one of which is a church. The Lake Runn is about ten miles long, and five wide.

The winter in this province is long and severe, the summer short and hot. Wheat does not succeed, but rye and barley are raised, though both frequently suffer from the early night-frost in autumn. The agricultural produce does not meet the demands of the scanty population, and the tender bark of pines is mixed with the bread, and also used as fodder for cattle and hogs. The cultivation of potatoes is rapidly increasing.

The usual domestic animals are reared, but hogs are

rather scarce. Game is abundant, especially different kinds of woodcocks, blackbirds, geese, ducks, and swans. Wolves and bears frequent the numerous and extensive forests. Fish abounds in all the lakes, except those near Falun.

The forests consist of birch, ash, aspen, pines, and fir, but they seldom grow up to timber trees. The fruits of some kinds of *rubus* are gathered for domestic use.

Near Falun are found copper, silver, gold, and brimstone. To the north of Elfedalen, on the Oester Dalelf, are quarries of beautiful porphyry, in which a small number of workmen are employed: the porphyry is made into vases, candlesticks, &c. of great elegance.

The population amounts to about 140,000, or a little more than 11 to each square mile. Except in the neighbourhood of Falun, to which place they are attracted by the mines, the population is dispersed over the country in villages, some of which are of considerable size. The Dalecarlians are distinguished by their stature, courage, spirit of independence, and frankness of character. The part which they took under Gustavus Vasa, in liberating their country from the tyranny of Christian II., is always fresh in their memory, and makes them feel proud of their name.

Dalecarlia forms one administrative province, or Län, called Falun Län, or Kopparbergs Län. The governor resides at Noor. Falun and Avestand are the most considerable places. [FALUN.] Nothing is exported but the produce of the mines and game, especially birds. (Thomson; Schubert's *Reise durch Schweden*; Harrison; Forsell, *Statistik öfver Sverige*.)

D'ALEMBERT. [ALEMBERT, D']

DALGARNO, GEORGE. The following short notice of this original but neglected author is in Anthony-à-Wood's *Athenæ Oxonienses*, vol. ii., p. 506. 'The reader may be pleased to know, that one George Dalgarno, a Scot, wrote a book entitled "*Ars Signorum, Vulgo Character Universalis et Lingua Philosophica*," London, 1661. This book before it went to press the author communicated to Dr. Wilkins, who, from thence taking a hint of greater matter, carried it on, and brought it up to that which you see extant. This Dalgarno was born at Old Aberdeen, and bred in the university of New Aberdeen; taught a private grammar-school with good success for about thirty years together in the parishes of St. Michael and St. Mary Magdalen in Oxford; wrote also "*Didascalocophus, or the Deaf and Dumb Man's Tutor*;" and dying of a fever on the 28th August, 1687, aged sixty, or more, was buried in the north body of the church of St. Mary Magdalen.' According to the above account, Dalgarno was born in or before the year 1627, and he must have been residing at Oxford in the year 1657; whether previous to that time, it does not appear, but it may not be erroneous to conclude that he went to Oxford to avail himself of the advantages of that seat of learning. Perhaps he lived there in the twofold capacity of student and teacher: Anthony Wood's work professes only to give a history of all the writers and bishops who have had their education in the famous university of Oxford, &c. From the works which Dalgarno left behind him, it may be concluded that he was a man of original talent, and of great acquirements; his speculations concerning a universal language, a favourite subject with the learned men of his time, undoubtedly preceded those of bishop Wilkins, at that time dean of Ripon, and he received the testimony of Dr. Seth Ward, the bishop of Salisbury, Dr. John Wallis, and others, that he had discovered a secret 'which by the learned men of former ages had been reckoned among the desiderata of learning.' We have carefully sought for some acknowledgment of the merits of Dalgarno in the 'Essay towards a Real Character' of bishop Wilkins, but the name of this obscure man is not once mentioned, though assistance from others is noticed, among whom the name of Dr. Ward appears. Wilkins's work was published in 1668. Its appearance had been delayed for two years in consequence of the whole impression, when nearly printed, with the exception of two copies, having been destroyed in the great fire of London. Allowing for this delay, Dalgarno's work had the priority by several years, and Dr. Wilkins had the advantage of seeing it 'before it went to press.' This treatise, '*Ars Signorum*,' &c., exhibits a classification of ideas, and a series of arbitrary signs or characters adapted to the classification, so as to represent each idea by a specific character, without reference to any language of words. All those persons who are acquainted with the Essay of Wil-

kins will see the germ of it in this design of Dalgarno's. The *Didascalocophus* develops views on the instruction of the deaf and dumb, both comprehensive and practical. It is a truly philosophical guide, by which the writer shows how capable the deaf and dumb are of understanding and applying a written language, and of their capacity to speak and to understand the speech of other persons. He shows that the art of teaching this class of persons requires the exercise of common sense, perseverance, and ordinary patience, under a teacher, fertile in expedients, and one who is able to turn even disadvantages and difficulties to a good account. How rational is the following: 'When your scholar is got over this difficulty of knowing and writing his letters, then imitate the way of the nursery. Let *utile* and *jucundum*, variety and necessity, invite and spur him on; specially if he be young, or of a lache (trifling) temper. You must not be too grammatical in teaching, till you find his capacity will bear it; he must not be dealt with as school-boys, who are often punished for not learning what is above their capacity. It is enough for him to understand the word or sentence proposed, without parsing every word or syllable; for this is all the use of language that not only children, but even people of age that are illiterate have.' (*Didascalocophus*, p. 53.) Much might be extracted from this little treatise to show how correct were Dalgarno's ideas on general instruction, as well as how accurately he had employed his thoughts on the teaching of the deaf. His style is quaint and pedantic, and rather abounds with long and technological words, which serve to exhibit the learning of the author more than to increase the perspicuity of his work. But this must be excused; it was the garb which learning assumed in his day. In the article DACTYLOLOGY a representation of Dalgarno's hand-alphabet is given. It is a gratification to find that his works are likely to be preserved, as they have been privately reprinted by Lord Cockburn and Mr. Thomas Maitland, and presented to the Maitland Club of Glasgow. Mr. Dugald Stewart has on more than one occasion paid a tribute of respect to Dalgarno; he mentions him in a note annexed to the first volume of the '*Philosophy of the Human Mind*,' as the author of a very ingenious tract, entitled '*Ars Signorum*;' and in his account of James Mitchell, a boy born blind, and deaf and dumb, he says, 'I feel myself called on to lay hold of the only opportunity that may occur to me, of rescuing from oblivion the name of a Scottish writer whose merits have been strangely overlooked both by his contemporaries and by his successors. The person I allude to is George Dalgarno, who, more than a hundred and thirty years ago, was led by his own sagacity to adopt, *a priori*, the same general conclusions concerning the education of the dumb, of which the experimental discovery, and the happy application, have, in our times, reflected such merited lustre on the name of Sicard.'

DALKEITH. [EDINBURGH, SHIRE OF.]

DALMATIA, the Kingdom of, the most southern possession of the crown of Austria, consists of a narrow maritime tract and numerous islands, forming part of the eastern boundary of the Adriatic, and lying between 42° and 45° N. lat. and 14° and 19° E. long. The Generalate of Carlstadt, in Hungary, bounds it on the north; the Turkish sandshak of Iskenderia on the east; and the Adriatic on the south and west. It is not a compact territory, inasmuch as the circle of Ragusa is disjoined from the rest of Dalmatia by two tongues of land, the Klek on the west, and the Suttarina on the east, which are Turkish. The area, inclusive of the islands, and according to the most recent estimate, is about 5098 square miles: Blumenbach, however, states it to be 5743. Dalmatia is divided into four circles, Zara and Spalatro, which constitute Old Dalmatia, and Ragusa (the territory of the former republic of that name) and Cattaro, which form New Dalmatia. The whole surface of Dalmatia is a series of mountain-ranges, some of which extend even into the Adriatic, and form islands with their loftier summits. With the exception of the Vellebich on the Hungarian border, which belongs to the Julian Alps, all these ranges are continuations of the Dinaric Alps. The loftiest summits among them are the Dinara, which is 5670 feet high, and gives its name to the main chain, the Promina, north of Dernis, 3610; the Svilaya, east of Dernis, 4750; Mount Mosor, 4210; Mount Marian, on the peninsula next Spalatro, and the Biokovo, near Macarsca, which is 5520 feet. To the south of these lie the ranges of Ragusa and Cattaro, among which

is the Dubovicza, the most southern mountain in the Austrian dominions. The Montenegrin heights encircle the gulf of Cattaro. The general character of the Dalmatian mountains is bleak and bare: they are full of fissures, ravines, and chasms, and in many places altogether without soil. Limestone is the prevailing rock. The numerous islands which line the coast have originated in the breaking up, by some violent action, of masses of clay and sandstone, while the limestone masses, being of firmer composition, have been left standing. The whole line of coast is barren and naked, except along the narrow tract between the Adriatic and the base of the mountains; forests and underwood lie interspersed at their feet; the background is formed by a continued line of dreary precipitous heights, seldom less than 2500 feet in elevation. The coast is indented in numerous points, and affords abundance of excellent harbours. The interior of the country is furrowed by glens and valleys, many of which are stony and sterile; even the plain extending from Novegradi to the Kerka is covered with stones. On the whole, there is no part of the Austrian empire which has so wild and desolate an aspect as Dalmatia.

Few countries are so poorly supplied with water, many parts being destitute of water fit even for the use of cattle: the islands in particular suffer greatly. The Dalmatian rivers run mostly from east to west into the Adriatic. Among the larger streams are the Zermanya (antiently the Tedanius), which enters from the Hungarian Military Frontiers, and, after a course of about 27 miles, falls into the bight of Morlach, near Novigrad; the Kerka (antiently the Titius), which rises above Knin, issues from a grotto, forms several cascades and five magnificent falls, particularly that by Scardona, in its course of about 51 miles, and, after receiving the Cicola, flows into the Adriatic near Sebenico. The Cettinu (Tilurus or Nestus), which springs from the foot of the Yerebiza, near Vrilo, has two falls in its course of about 60 miles, one of which is from 90 to 100 feet in height, and occurs near Velika-Gubowicja: the banks of this river are extremely wild, and generally precipitous, until it reaches a fine valley near Amissa, where it enters the Adriatic. The Narenta (Naro of the antients), the broadest river in Dalmatia, enters it from Turkey, and, after watering it for about ten miles, parts into two channels at Fort Ovus, and reaches the canal of Narenta through ten arms. Its waters are saltish until it receives the Norin at Torre di Norin. Among the smaller rivers are the Sinkotina and Ombla.

The islands along the Dalmatian coast form several fine channels, which are sheltered from the stormy waves of the Adriatic: they are here called canals, and take their names from the adjacent islands; such are the canals of Morlak, Quarnerola, Zara, and Pasman, Mezzo, Spalatro, Lissa, Curzola, Narenta, &c.

Dalmatia is full of lakes, all of which become more or less dry in hot weather, except the Vrana, to the south-east of Zara, which is separated from the Adriatic by a narrow tongue of land, contains an area of about 8570 acres, and has brackish water. The lakes of Novigrad, Yezero (the dry bed of which is at times cultivated), Narin, Kadin, Trocklian, Prelosaz, &c. become dry at certain seasons from the want of natural springs. None of the numerous mineral springs have yet been turned to account, except the warm sulphureous springs at Spalatro and Salona.

No part of the Austrian dominions is so hot as Dalmatia. In the lowlands the date-bearing palm, the American aloe, and the Cactus opuntia thrive in many districts in the open air. The almond blossoms in January. Among the mountains, where the snow sometimes continues till May and even June, the climate is much bleaker. Near the coasts of Zara, about the canal of the Narenta, and elsewhere on the Adriatic, the exhalations which arise from extensive swamps render the climate very unhealthy. Winter is characterized by six weeks of uninterrupted rain.

The arid character of the soil renders Dalmatia on the whole unsuited to agriculture. But there are parts of the country, such as the districts around Dernis, Muk, and Sign, which might be cultivated with success, but for the indolence and ignorance of the people. The want of water and sheltering woods is another obstacle to cultivation. Turkey and Hungary supply the constant deficiency in the crops of grain, which do not furnish more than six or at most eight months' consumption. The whole amount of arable land does not exceed 191,190 Paduan

campi. Barley and oats are the corn mostly grown. Figs may be termed almost the staple produce of the country: the export is about 845,000 pounds weight yearly. The oil is of superior quality, and used by the natives instead of butter; yet above 21,000 barrels are annually exported. Much wine of a strong quality is made; the deeper the colour, the more powerful the liquor: the Vino Nero, a red wine, is nearly black, and the white wine as deep in colour as Malaga: the Marzenin del Teodo is the best. About 8,000,000 gallons (the whole produce being about 9,120,000) per annum are exported to Fiume, Trieste, and Venice. Almonds, dates, dried currants, citrons, pomegranates, oranges, and other fruits are exported. The country abounds in timber, but being in the interior, it is almost inaccessible: the forests in the neighbourhood of the coast have been exhausted. The coast fisheries employ about 8000 hands: the staple kinds of fish are the sardinia and the tunny, both of which are exported in a dried or salted state. The rivers too are well supplied, particularly with the salmon-trout, which attains an enormous size. Altogether, the value of this branch of trade is estimated at 300,000*l.* a year and upwards. At some spots the coral fishery is productive, especially near Sebenico. The Morlaks convert the fat of the frog into an oil, which they employ for various purposes. Honey and wax are produced in some quantities.

The rearing of cattle is on a limited scale: the breeds are inferior and small: the whole stock of oxen, cows, sheep, and goats is not estimated at more than about 800,000, of which 53,000 only are oxen. The number of draught and saddle-horses is about 22,500, and of mules about 3906. Pains are taking, by the introduction of Merinos, to improve the breed of sheep, the native race being of diminutive size, and the fleece short and coarse. The stock of goats and swine is limited; but poultry, except geese and ducks, plentiful. There has in fact been a great diminution in the number of horses, cattle, and sheep during the last thirty years; for it appears by the returns of 1808 to have amounted at that time to 1,271,218, of which there were 1,105,078 sheep alone.

Of wild animals, Dalmatia possesses the Ciaghlo, or wild dog, wolf, fox, and hare, but it has no deer: swans, pelicans, falcons, vultures, owls, turkeys, and other wild fowl are abundant.

Dalmatia is rich in minerals, particularly limestone, gypsum, coal, pitch, asphaltum, and sea salt. No precious metals have been discovered, although Pliny (iii.) reports that the Dalmatian mines yielded as much as 50 pounds weight of gold per diem in Nero's time. These mines, however, cannot have been within the limits of the present territory of Dalmatia.

The majority of the inhabitants are descendants of the Slavonian hordes, who invaded these parts in the seventh century and drove out the old inhabitants. The language of the country is the Herzogovine dialect of the Slavonian, but Italian is the prevalent tongue among the well-educated classes, and is used in the public offices and courts. The remainder of the population is composed of Italians (about 40,000), who are spread throughout the maritime towns and sea-coast; Bosnian Greeks (about 10,000) and Servian Morlaks (about 80,000), both of whom took refuge here from persecution in the fourteenth century. The Morlaks or *Moroflachi*, *i. e.* Servians, who dwell next the sea (*Moro*), inhabit the mountain-districts of the Zara and Ragusa and some of the islands: the wild Montenegrin is of this race. The population of Dalmatia, which had been on the increase in the early part of the present century, inasmuch as the numbers rose from 256,863 in 1808 to 305,671 in 1815, and 324,075 in 1822 fell to 323,112 in 1825, and according to Blumenbach, cannot now be estimated at more than 320,000. In general the Dalmatian is of good stature, muscular, robust, hardy in his habits, and frugal in his diet: he lives much in the open air and under tents. The poorest man drinks his wine, and eats his salad, fig, and melon: he is hospitable and talkative, but cunning, and addicted to lying and theft. There are some Germans and about 500 Jews settled in the country, the latter of whom are the descendants of Spanish colonists, who were expelled from Spain about the year 1502. Some few Greeks are settled in Dalmatia, as well as several tribes of gipsies, in number about 1800, who chiefly haunt the neighbourhood of Verlika and Sign.

The Roman Catholic, which is the established religion, is

professed by at least four-fifths of the people. The ecclesiastical establishment consists of the archbishop of Zara and the 5 bishops of Spalatro, Ragusa, Sebenico, Lesina with Lissa, and Brazza and Cattara: they have under them 378 cures of souls, 60 monasteries, and 9 nunneries. The inhabitants, who profess the Greek faith, are in church-matters subordinate to a bishop resident at Sebenico and the vicar-general at Cattaro, under whom are 11 monasteries and 119 benefices.

Dalmatia is divided into the following circles:—

	Area.	Number of Inhabitants.	Districts.	Towns.
	Sq. M.			
Zara . . .	2121	114,000	7	{ Zara, cap. of Dalmatia, 7900 inhabitants; Sebenico, 4000; Scordona, 1200.
Spalatro or } Spalato . }	2656	133,000	10	{ Spalatro, cap., 7300; Trau or Troglie, 2900; Macarsca, 1300.
Ragusa . .	588	41,000	6	{ Ragusa, cap., 5000; Curzola, 6200.
Cattaro . .	378	32,000	3	{ Cattaro, cap., 2600.
	5743	320,000	26	

The circle of *Zara* comprises the Quarneric, Dalmatian, and Culadic islands; that of *Spalatro*, the islands of Zirona Grande, Bua, Solta, Lissa, Brazza, and Lesina; and that of *Ragusa*, the islands of Calamotta, Meleda, Lagosta, Curzola, and Pelagosa Maggiore.

Dalmatia contains 9 municipal towns, 14 market-towns, and 988 villages, and about 63,500 houses. The will of the sovereign is the law of the land, and there is no representative body or provincial states as in the native dominions of Austria; but certain districts and towns have been allowed to retain the rights and privileges which they possessed when under the dominion of the republic of Venice. Poglizza alone, a mountain district of about 16,000 or 17,000 souls, including several Hungarian and Bosnian nobles, in the circle of Spalatro, is so far independent that it elects its Gran Conte, or governor, and its local elders and magistrates, in the general assembly of the people called Zdor, which is held every year in the plains of Gatta. Every male is a soldier, and the district pays a tribute in lieu of taxes. The general administration of affairs in Dalmatia is vested in the Gubernium or government-board established at Zara, which receives its instructions from the Chancery and minister of the Home Department in Vienna. Each circle is divided into districts; each district into 'Haupt-gemeinden,' or head communities; and each of the latter consists of 'Unter-gemeinden,' or subordinate communities. At the head of each circle, in civil matters, is a 'Pretoria;' of each head community, a 'Podesta,' or 'Sandako;' and of each subordinate community, a 'Capo-villa,' or 'Casnazzo.'

The revenues of Dalmatia arise from the imperial domains, which yield about 10,000*l.* per annum; the regalia, which include the monopoly of salt, about 25,000*l.*; the direct taxes, about 39,000*l.*; and the indirect taxes, about 21,000*l.*: altogether about 95,000*l.* a year. Von Lichtenstern estimates the expenditure, exclusive of the military establishments, at about 72,900*l.* per annum. Dalmatia furnishes four battalions of Sharpshooters for the imperial service.

The manufacturing industry of this country is very small, and scarcely adequate to supply its common wants: it is confined to the townspeople, and its main branches are shipbuilding and the distillery of spirits, among which the liqueur called Maraschino-Rosoglio has obtained European celebrity. Here and there a little flax and cotton are spun, and small quantities of woollen cloth, coverlids, house linen, tape, and coarse cottons, twine, cordage, and nettings, soap, vinegar, leather, and hats are made. For every other article of necessity or comfort Dalmatia is dependent on other countries. 'There is clay,' says Blumenbach, 'but no potter; quartz, but no glass-work; timber, but no carpenter; lime, but no kiln; coals, but no mine; iron, but no furnace; skins, but no leather-maker; and rags, but no paper-mill. To this hour the hand-mill is universally used.' What must be the state of a country of which even a native can thus write!

Favoured as Dalmatia is by its situation and numerous ports, its commerce is comparatively small. The principal countries with which it trades are the maritime pro-

vinces of Austria, Italy, and Turkey. To the first two countries it exports wine, olives, oils, brandy, figs, salt, pitch, bark, salted fish, hides, wool, wax, honey, fruit, &c., and to Turkey the same products, besides foreign produce and manufactures. It has also some transit trade. Its returns from Turkey consist of horned and fatted cattle, cheese, wools and hides, corn, wood for fuel, drugs, &c. Dalmatia is not included with the other Austrian possessions under its onerous system of customs-imports, and its trade is therefore almost unshackled. The Dalmatians are well known in the Adriatic and Mediterranean as excellent mariners, and possess between 2900 and 3000 vessels of their own, varying in burthen from 40 to 500 tons: their best ships are constructed along the coast of Cattaro.

The Austrians found the country in a wretched state of ignorance, for the Venetians had done nothing whatever for its intellectual improvement. But the present government has commenced the good work by making pecuniary grants for the establishment of schools for the lower orders, and for encouraging the clergy to give instruction to their flocks. A normal seminary and school for girls have been opened at Zara; national schools of a superior class have been established at Spalatro, Macarsca, Ragusa, Cattaro, Sebenico, and Lesina, independently of the schools attached to the convents. And for the more affluent classes, gymnasias have been instituted in Zara, Spalatro, and Ragusa, and a lyceum or species of university at Zara, in which town there are likewise an ecclesiastical seminary, an obstetrical school, and a college for educating 37 pupils at the public expense. The benevolent institutions are as yet confined to the hospitals and founding asylums at Zara, Sebenico, Spalatro, Lesina, and Cattaro, and the infirmary at Ragusa.

Dalmatia derives its name from the Dalmatine, a small district between Sebenico and Scordona. Its territory in former days was much more extensive than at present. The Dalmatians long resisted the Romans, but Augustus brought them under the Roman dominion. (Strab., p. 315.) After the fall of the western empire, the country became a prey to the Goths and Avari successively, and the latter maintained possession of it until the beginning of the seventh century, when they were driven out by swarms of Sclavonians. This people erected it into an independent sovereignty, which endured until overthrown by Ladislaus, king of Hungary, in the early part of the eleventh century: this monarch annexed the whole of it, the maritime towns only excepted, to the dominion of the Magyars. These towns, among which was Zara, the most important of them, had long been under the special protection of Venice, which availed itself of the connexion to extend its sway over other parts of the country, and bring the greater part of Dalmatia under subjection. That portion which lay on the right bank of the Zermanya, and which Hungary retained, lost the name of Dalmatia altogether; and the same occurred with regard to the portion which forms part of Bosnia, and fell into the hands of the Turks, by whom it was erected into the sandshak of Hersek. The Austrians acquired the Venetian part of Dalmatia in 1798 under the treaty of Campo Formio. (Blumenbach; *Austrian Encyclopædia*; Von Lichtenstern; Hassel; Stein; Roprer, &c.)

DALRYMPLE FAMILY. The surname of this family is derived from the lands of Dalrymple, in the shire of Ayr, of which, in remote times, the chief of the house was proprietor. The family appears to have been of importance very early, for in the reign of King Robert III., Duncan Dalrumpill had a charter of the office of Toscheodorach (or principal executive officer of the crown) in Nithsdale; and in 1462 James de Dalrymple was clericus regis.

The lands of Stair, whence the viscounty and earldom are derived, came into the family by William de Dalrymple, who became possessed of them in the middle of the fifteenth century by his marriage with his relation, Agnes Kennedy, heiress of the estate. The son of these parties married a daughter of Sir John Chalmers, of Gadgirth, in the same shire, whose first ancestor had held the high office of chamberlain of Scotland; and in lineal descent from him was James de Dalrymple of Stair, who married Janet, daughter of Kennedy of Knockdaw, and by her had

JAMES DALRYMPLE, first viscount Stair. He was born in May, 1619, at Dummurichie, in the parish of Barr, county of Ayr, and lost his father before he had attained his fifth year. At that tender age he was left under the guardianship of his mother, who survived her husband

upwards of thirty years. His early education was acquired at the school of Mauchlin, whence, at the age of fourteen years, he was removed to the college of Glasgow, where, applying himself closely to his studies, he gained the approbation of his teachers, and qualified himself for taking the degree of A.M. in 1637. He left college the following year, and at the breaking out of the civil war obtained a captain's commission in the earl of Glencairn's regiment.

About this time the chair of philosophy in the university of Glasgow became vacant, and having, by the advice of some of the professors, become a candidate, he was in 1641, being then twenty-two years old, appointed to the place after a comparative trial. It was then the practice for every regent to swear at taking office to demit on his marriage. This Dalrymple did, and having in 1643 married Margaret Ross, co-heiress of the estate of Balneil in Wigton, he resigned the chair, but was soon afterwards re-appointed. In this place he sedulously pursued his studies, and particularly the study of the civil law, with the view to the profession of the law, in which a knowledge of the Roman jurisprudence was then of great moment. In 1647 he resigned his chair, came to Edinburgh, and after the usual trials, was admitted an advocate on the 17th February, 1648. The following year he was appointed secretary to the commissioners sent by the Scottish parliament to treat with Charles II., then an exile in Holland, for his return to his native dominions. He held the same office in the more successful mission of 1650, and was on that occasion particularly noted for his 'abilities, sincerity, and moderation.' In 1654 we find him on a committee of four, deputed by the Faculty of Advocates to wait upon the judges for the purpose of getting the antient form of the Outer House restored; and he was indeed well known both at the bar and in the country.

During the Protectorate he was recommended to Cromwell by General Monk, as a fit person to be one of the judges of the court of session. In his letter, dated from Edinburgh, 23rd June, 1657, Monk says, 'I make bold to mention to your highness one Mr. James Dalrymple, as a person fit to be a judge, being a very honest man, a good lawyer, and one of considerable estate. There is scarce any Scotsman, or Englishman who hath been much in Scotland, but knows him, of whom your highness may enquire farther concerning him.' The general wrote again to the Protector on the subject a few days after, and on the 1st July, 1657, Dalrymple took his seat on the bench.

At the Restoration he went to London with the earl of Cassilis to pay his respects to the king. On that occasion the honour of knighthood was conferred upon him; and by letter, dated Whitehall, 14th February, 1661, he was also nominated one of the lords of session. He was soon afterwards much annoyed however by the declaration enacted in 1663, and continuing to refuse signing it, his place was declared vacant 19th January, 1664. He thereupon set out with his eldest son on a tour to the continent; and having waited on the king at London on his return, his majesty allowed him to qualify his subscription to the Declaration, and restored him to his seat. As a farther proof of the royal favour, he was created a baronet on the 2nd June of the above year, 1664; and on the resignation of Sir John Gilmour, he was appointed president of the court of session 7th January, 1671.

On the 28th February, 1672, his eldest son, *John*, was admitted an advocate before the court: on the 25th June, 1675, his next son, *James*, was admitted; and his third son, *Hew*, on the 23rd February, 1677. A short time before this last date, the town-council of Edinburgh, 'having taken into consideration the many great and signal services done to the city by Sir James Dalrymple, president of the court of session,' resolved that his house-rent should be paid by the town during his life, as also that of all his successors in office.

Dalrymple continued president till the year 1681, when, on account of his conduct on occasion of the Test Act, he was superseded, and found it necessary to retire into Holland.

In 1681 he published his '*Institutions of the Law of Scotland*,' the work of a great and philosophic mind, but one deeply imbued with the principles of the Roman jurisprudence: it gave consistency to the body of Scots law; and till our own day has guided the determinations of the Scottish lawyers. From his retirement at Leyden he transmitted to the Edinburgh press his '*Decisions of the Court of Session from 1661 to 1681*;' the

first volume appearing in 1684, and the second in 1687. And in 1686 he published at Leyden his '*Philosophia Nova Experimentalis*.' He also busied himself about this time on a work relating to the mutual obligations of the sovereign and his people, but it was never published.

On the accession of King James II., Dalrymple's eldest son was appointed lord advocate of Scotland in the room of Sir George Mackenzie; and in this place he had influence enough to procure a pardon for his father, who, on the testimony of Spence, the secretary of Argyle, had been prosecuted and outlawed for his alleged concern in the Rye-house Plot. Sir John held the situation of lord advocate for about twelve months, when he was appointed successor to Foulis of Colinton, both as lord justice clerk and as an ordinary lord of session. His father, on coming over to this country with the Prince of Orange, with whom he had been much in favour while in Holland, was reinstated in the presidency of that court; and on the 21st April, 1690, raised to the peerage by the style and title of viscount Stair. The same year Sir John was re-appointed lord-advocate; and the next year advanced to be one of the principal secretaries of state, in which latter place he continued till the year 1695, when he was driven from office upon the parliamentary inquiry into the equally impolitic and barbarous massacre of Glenco, as to which he bore so much blame.

Stair died in the end of the same year, on the 23rd November, 1695, shortly after the publication of his work entitled '*A Vindication of the Divine Perfections*,' and was buried in the high church of Edinburgh. He was succeeded in his title and estate by his eldest son, who, on the 8th April, 1703, was advanced to be earl of Stair. This person died suddenly on the 8th January, 1707, after a warm debate that day on the 22nd article of the treaty of Union which relates to the number and privileges of Scots peers. By his wife, daughter and heiress of Sir John Dundas, of Newliston, in the shire of Edinburgh, he left a younger son, who was

JOHN DALRYMPLE, second earl of Stair. He was born at Edinburgh on the 20th July, 1673, and in early youth had the misfortune to kill his elder brother by the accidental discharge of a pistol. For some years afterwards he was under the tuition of a clergyman in the shire of Ayr, whence he was at length restored to his father's house.

In 1692, when but a youth of nineteen, he entered as a volunteer under the earl of Angus, commander of the Cameronian regiment, at the battle of Steinkirk. His parents however appear to have been desirous of his adopting the profession of the law, and for that purpose sent him to Leyden; but on his return in 1701 from his travels, he accepted a commission as lieutenant-colonel of the Scots regiment of Foot Guards. The year following he served as aide-de-camp to the duke of Marlborough at the taking of Venlo and Liege and the attack on Peer; and in the course of the year 1706 he successively obtained the command of the Cameronian regiment and the Scots Greys. On his father's death in the beginning of 1707 he succeeded to the earldom of Stair; and was soon afterwards chosen one of the representative peers of Scotland in the united parliament. In the subsequent victories of Oudenarde, Malplaquet, and Ramillies, he held high command and obtained great distinction; but on the accession of the new ministry in 1711, when the career of Marlborough was stopped, he sold out of the Scots Greys, and retired from the army.

When George I. succeeded to the throne the earl of Stair was appointed a lord of the bedchamber and a privy councillor, and, in the absence of the duke of Argyll, was constituted commander-in-chief of the forces in Scotland. The next year he was sent on a diplomatic mission to France; and it would seem that the embassy was distinguished by much skill and address, and at the same time by remarkable splendour and magnificence. He was recalled in 1720, and for the next twenty-two years lived in retirement at his seat at Newliston, where, it is said, he planted various groups of trees in a manner designed to represent the arrangement of the British troops at one of the victories he had been engaged in. He also turned his attention to agriculture, and was the first in Scotland to plant turnips and cabbages in the open fields.

On the dissolution of the Walpole administration in 1742, he was recalled to public life, and served in a military capacity on different important occasions till his death, which

happened at Queensberry-house, Edinburgh, on the 9th May, 1747. He left a widow, but no children.

His next brother, *William Dalrymple*, of Glenmure, who was a colonel in the army, married Penelope, countess of Dumfries, and their issue succeeded to the earldom. His youngest brother, *George Dalrymple*, of Dalmahoy, passed advocate, and on baron Smith's advancement to the chair, was made a puisne baron of Exchequer, in which situation he continued till his death in July, 1745. More lately, there was on the bench of the same court, a member of another branch of the same family, *Sir John Dalrymple*, of Cranstoun, Bart., who was appointed in 1776 one of the barons of the Exchequer, and so continued till the year 1807, when he resigned. He was the author of 'Memoirs of Great Britain,' 'Tracts on Feudal Law,' and other publications. He was descended from *James*, second son of the first viscount Stair, who was author of 'Collections concerning Scottish History preceding the Death of David I.,' and who was created a baronet on the 28th April, 1698, the day previous to his younger brother, *Hew Dalrymple*, of North Berwick, being raised to the like dignity.

This *Sir Hew Dalrymple* was some time one of the commissaries of Edinburgh, having been appointed to that place on the resignation of his brother *James*, when the latter was made one of the principal clerks of session. He had also been some time Dean of the Faculty of Advocates; and was now, on the occasion of his being created a baronet, promoted at once from the outer bar (like the predecessor of his father, *Sir George Lockhart*, and in more recent times *Mr. Blair*, the only instances in the history of the court) to the presidency of the Court of Session, which had remained vacant since his father's death in 1695. President *Sir Hew Dalrymple* collected the decisions of the court from his appointment till the 21st June, 1720, and continued in the chair till his death, which took place on the 1st February, 1737, in the eighty-fifth year of his age. *Lord Woodhouselee* says of him in his *Life of Kames*,—'If he inherited not the distinguished talents of his father the viscount of Stair, and his elder brother the secretary he was free from that turbulent ambition and crafty policy which marked the characters of both; and, with a sufficient knowledge of the laws, was a man of unimpeached integrity, and of great private worth and amiable manners.'

He had a younger son of the same name with himself, *Hugh Dalrymple*, who passed advocate on the 18th November, 1710, and in December, 1726, was made a lord of session under the titular designation of *Lord Drummore*. He was also, some time afterwards, appointed a lord of justiciary on *Erskine of Dun's* resignation, and died in the possession of both offices in June, 1755, with the character of an acute and learned lawyer and a very honourable man. By his wife, *Anne Horn*, heiress of the estates of *Horn* and *Westhall*, in the county of *Aberdeen*, he left a large family, one of whom was *David Dalrymple*, of *Westhall*, who passed advocate in the beginning of 1743, in the twenty-third year of his age, and in 1746 was chosen procurator (or advocate) to the Church of Scotland. In 1748 he was also constituted sheriff depute of the shire of *Aberdeen*, and he continued in both offices till July, 1777, when he was made a lord of session under the title of *Lord Westhall*. His elder brother assumed his maternal surname of *Horn*, and marrying *Mary*, daughter and heiress of *Sir James Elphinstone*, of *Logie*, assumed the additional surname of *Elphinstone*, and had by his wife a son, who, on the 16th June, 1828, was created a baronet by the style and title of *Sir Robert Dalrymple Horn Elphinstone*, Bart., of *Horn* and *Logie Elphinstone*. A younger branch of the same family had, a few years before, been raised to the like dignity in the person of *Sir Hugh Whiteford Dalrymple*, of *Highmark*, in the county of *Wigton*, who was created a baronet on the 6th May, 1815.

The youngest son of the first Viscount Stair was *Sir David Dalrymple*, of *Hailes*, Bart., so created on the 8th May, 1700. He passed advocate on the 3rd November, 1688, and in 1709 was appointed lord-advocate of Scotland in the room of *Sir James Stewart*, who was however reinstated in the office in the year 1711. On *Stewart's* death, *Sir David* was again appointed lord-advocate, and continued till May, 1720, when he was succeeded by *Robert Dundas*, of *Arniston*, who also succeeded him on his decease, the following year, in his place of Dean of the Faculty of Advocates. His eldest son was *Sir James Dalrymple*, of *Hailes*, Bart., some time auditor of exchequer; and by his wife,

Lady Christian Hamilton, daughter of the sixth earl of *Haddington*, the father of a numerous family.

The eldest of these was the celebrated judge and antiquary,

Sir DAVID DALRYMPLE, better known by his titular designation of *Lord Hailes*. He was born at *Edinburgh* on the 28th October, 1726, and after acquiring the rudiments of his education in his native place, was sent to *Eton*, where, with a competent degree of learning, he imbibed that classical taste, and partiality for the manners and customs of *England*, which distinguished the subsequent periods of his life. From *Eton* he returned to *Edinburgh*, whence, after passing through the usual course at the university there, he was sent to *Utrecht* to study the civil law; and on his return, in 1746, he prepared for the bar, and passed advocate on the 24th February, 1748. After eighteen years of professional life, he was raised to the bench of the Court of Session; and ten years afterwards he was also, on the resignation of *Lord Coalston*, to whose only daughter he was married in October, 1763, appointed a lord of justiciary. As a judge, his accuracy, diligence, and dignity, were eminently conspicuous; but it is on the broader basis of literary merit that his great fame rests.

The earliest of his publications appears to have been sacred poems, being a collection of translations and paraphrases from scripture, by various authors, *Edinb.*, 1751. His next was the 'Wisdom of Solomon, and the Book of Ecclesiastus,' 1755. The same year he wrote in 'The World' Nos. 140 and 147, and the next year No. 204, in which year also he published 'Select Discourses,' by *John Smith*, of *Cambridge*, with a preface and learned notes. The year following, 1757, he republished, with notes, 'A Discourse of the unnatural and vile Conspiracy attempted upon the King by the Earl of Gowry.' In the month of October, 1761, two vessels being wrecked on the shore between *Dunbar* and *North Berwick*, and pillaged by the country people, *Sir David* published a Sermon, from *Acts xxviii.*, 2:—'The barbarous people showed us no little kindness.' In 1762 he published, from the press of *Foulis*, of *Glasgow*, 'Memorials and Letters relating to the history of Britain in the reign of *James I.*, of *England*,' with a preface and notes. From the same press, in 1765, he published the works of the ever memorable *Mr. John Hailes*, of *Eton*, in 3 vols.; and the same year at *Edinburgh* the first specimen of a book entitled 'Ane compendious booke of Godly and Spiritual Songs.' The year following he published 'Memorials and Letters relating to the history of Britain in the reign of *Charles I.*,' from the originals collected by *Woodrow*; an 'Account of the Preservation of *Charles II.* after the battle of Worcester,' drawn up by himself; and the 'Secret Correspondence between *Sir Robert Cecil* and *James VI.*' The next year he published a catalogue of the lords of session from the institution of the court, with historical notes; and the following year, 'The private correspondence of *Bishop Atterbury* and his friends in 1725.' In 1769 he published, first, 'An Examination of some of the arguments for the high antiquity of the *Regiam Majestatem*, and an inquiry into the authenticity of the *Leges Malcolmi*;' 'Historical Memoirs concerning the provincial councils of the Scottish clergy, from the earliest account to the æra of the Reformation'; and third, 'Canons of the Church of Scotland, drawn up in the provincial councils held at *Perth* in the years 1242 and 1269.' And in 1770 he published some antient Scottish poems from MSS., with a number of curious notes and a glossary. His next performance was the additional case of *Elizabeth*, claiming the title of Countess of *Sutherland*: a singularly able paper, which was subscribed by *Alexander Wedderburn*, afterwards Lord Chancellor of *England*, and *Sir Adam Ferguson*, but well known to be the work of *Lord Hailes*. In 1773, *Sir David* published 'Remarks on the history of Scotland;' and in 1776, 'Letters from *Hubert Languet* to *Sir Philip Sydney*.' This last year also he published his 'Annals of Scotland, from the time of *Malcolm Canmore* to *King Robert I.*;' 'Tables of the succession of the Scots Kings' during the same period; and in 1779, his 'Annals of Scotland, from the accession of *Bruce* to the accession of the House of *Stuart*.' In the above year, 1776, he published another work of great erudition; namely, 'An account of the Martyrs of *Smyrna* and *Lyons* in the second century,' with notes. This was intended as the first vol. of 'Remains of Christian Antiquity;' the second vol. of that work appeared in 1778; and the third in 1780. The next year he

published 'Octavius,' a dialogue by Marcus Minucius Felix, with notes and illustrations; and the year following, the treatise, by Lactantius, of the manner in which the persecutors died, illustrated in like manner by various notes. In 1783 appeared his disquisitions concerning the antiquity of the Christian Church; and in 1786, an inquiry into the secondary causes which Mr. Gibbon has assigned for the rapid growth of Christianity. After this followed some biographical sketches, in separate works, and at different times, but all intended as a specimen of a *Biographia Scotica*. In 1788 he published from MSS. the opinions of Sarah, duchess of Marlborough; and in 1790, a translation of the address of Q. Septim. Tertullus to Scapula Tertullus, proconsul of Africa, with notes, to illustrate the state of the church in early times.

This was the last work which Lord Hailes lived to publish. On the 29th November, 1792, he expired, in the sixty-sixth year of his age, the baronetcy, for want of male issue, descending to his nephew, James, eldest son of John Dalrymple, Esq., some time lord provost of Edinburgh, who was brother of Sir David, and also brother of

ALEXANDER DALRYMPLE, the hydrographer. He was born at New Hailes, the seat of his father, Sir James Dalrymple, Bart., on the 24th July, 1737, and was the seventh son of a family of sixteen children, all of whom he survived. His scholastic education was very limited, partly from the troubles of the times, and partly from the early death of his father; and when scarce sixteen years of age, he went abroad as a writer in the East India Company's service. Owing to his deficiency in the ordinary branches of learning, he was, on his arrival in India, placed under the storekeeper; but at length, through the kindness of friends, he was removed to the secretary's office, Lord Pigot himself giving him some lessons in writing, and Mr. Orme, the historian, instruction in accounts.

In the records of the secretary's office he found certain papers on the subject of a commerce with the Eastern Archipelago; and so interested in the subject did he become, that contrary to Lord Pigot's advice, he refused the secretaryship, and determined on a voyage among the eastern islands. He now also made himself master of the Spanish language by his own efforts, as he had a short time before done in regard to the French. In the course of the voyage he concluded a commercial treaty with the sultan of Sooloo; but not long afterwards the political affairs of that place were altogether changed, and no beneficial effects resulted from the enterprise. He subsequently returned to Sooloo, and re-established a friendly understanding between the inhabitants and the company; but unfavourable circumstances again intervened to prevent the results which were anticipated, and his exertions in England, whither he afterwards came on the same matter, were equally unfortunate. He appears indeed to have been peculiarly exposed to the influence of an adverse fortune; for besides the instances already given, he had, when in England in 1776, been promised by the earl of Egmont, on the urgent recommendation of Lord Howe, to be appointed hydrographer to the admiralty, with a salary of 500*l.* a year, and afterwards of being employed on an expedition of discovery to the South seas, and on a mission to observe the transit of Venus; but from various causes he received none of these appointments. At length, in 1769, the Court of Directors voted him 5000*l.* for his past services, equivalent to the emoluments of secretary at Madras, which he had relinquished in 1759 to proceed on the eastern voyage.

From the time of his return to England, in 1765, he employed himself in collecting materials for a full exposition of the importance of the Eastern islands and South seas; and the Court of Directors, satisfied of the important information he possessed, employed him to draw up several charts of the eastern seas, which were published under their authority.

On Lord Pigot's appointment to be governor of Fort St. George, in 1775, Dalrymple was reinstated in the service of the East India Company, and went out to Madras as a member of council and one of the committee of circuit; but in 1777 he was recalled, with others, under a resolution of the general court, to have their conduct inquired into, though nothing appears to have been done thereupon. Two years afterwards he was appointed hydrographer to the East India Company; and in 1795, when the admiralty at last established the like office, it was given to Dalrymple. This place he retained till 1808. In May of that year the admiralty insisted on his resignation on the ground of superannuation,

and it certainly appears that he exhibited symptoms of decayed faculties and an irritable habit. He refused to resign however, upon which they dismissed him from the place; and on the 19th of the following month he died, it is said from vexation, in the seventy-first year of his age.

He left a large library, and rich particularly in works on navigation and geography, a few of which were purchased by the admiralty, and the remainder were sold by auction. His own works amount to about sixty in number; many of them undoubtedly valuable, but some also of a merely personal and transitory character. A list of them is appended to a memoir of the author, furnished by himself, in the 'European Magazine' for November and December, 1802.

DAMAGES (old French *damage*, Latin *damna*), in law, signifies the compensation that is given by the jury (or assessed by the court) to the plaintiff or demandant for the wrong the defendant has done to him. The word is taken in the law in two several significations; the one properly and generally, the other strictly and relatively. Properly, as it is in cases where damages are founded upon the statute 2 Henry IV. and 8 Henry VI. c. 9, where costs are included within this word damages; for damage, in its proper and general signification, is said (though improperly) to come from *à demendo*, when a thing by diminution is made worse; and in this sense costs of suit are damages to the plaintiff, for by them his substance is diminished. But when the plaintiff declares the wrong done to him, to the damage of such a sum, this is to be taken relatively for the wrong which is passed before the writ brought, and cannot extend to costs of suit, which are future and of another nature. (Cowel's *Interpreter*.)

At common law damages were recoverable in personal and mixed actions, but not in real actions, because, says Sir Ed. Coke, in his commentary on the statute of Gloucester, 6 Edward I. c. i., 'the court could not give the demandant that which he demanded not, and the demandant in real actions demanded no damages, neither by writ nor count.' Till the right to the land was determined, the party could not be said to suffer wrong; but after the recovery, damages might be laid in a personal action; but by the above statute damages and costs are made recoverable in certain real actions, as in 'Dower,' 'Entry sur disseisin,' &c. But such actions were, strictly speaking, mixed, though they were usually denominated real. Though all real actions have been recently abolished, the right to land being now triable in all cases by ejectment, it was necessary to refer to them to explain the nature of damages. In ordinary cases, where the title to land is in dispute, the damages are merely nominal, the actual damage sustained by the detention of the property being recovered in an action of trespass for the mesne profits, except only in ejectment by a landlord against a tenant, where damages in the nature of mesne profits may be given by statute 1 George IV. c. 87, § 2. In all actions which sound in damages (*i. e.*, where compensation for wrong is sought), as *assumpsit*, &c., the amount of the damages is determined by the jury, though they cannot give more than the amount laid in the declaration. In actions of debt the plaintiff seeks to recover a specific sum, and not a compensation in damages; the damages therefore for the detention of the debt are generally merely nominal, except in those cases where, by the recent alterations in the law, the jury is empowered to give damages in the nature of interest. [DETINUE.]

Where the parties have stipulated for a liquidated sum to be paid as damages, the jury are bound to give the full amount of that sum; but where they have stipulated merely for a penalty to be paid [PENALTY], the jury may give less, or if the parties do not proceed for the penalty, they may give more. There are several cases in which double and treble damages are given by statute. If the damages given be excessive, the court will sometimes grant a new trial, but not so if they be too small; at least it is very unusual to do so, except in actions on mere money demands or on inquiries. (Co., *Litt.*; Tidd., *Pract.*)

DAMASCE'NUS, JOANNES, was born at Damascus towards the end of the seventh or the beginning of the eighth century of our æra. His father, Sergius, a wealthy Christian of Syria, was councillor to the caliph, and at his death John succeeded him in the same office. His father had given him for preceptor a monk named Cosmas, whom he had redeemed from slavery. About A.D. 728 he wrote several tracts in defence of image worship against the Iconoclasts, who were then favoured by the Emperor

Leo the Isaurian. A legendary story is told of Leo having forged a treasonable letter from John to himself, which he contrived should come into the hands of the caliph, who sentenced John to have his right hand cut off, when the severed hand was restored to the arm by a miracle. About that time however John withdrew from the caliph's court to the monastery of St. Saba, near Jerusalem, where he passed the remainder of his life in ascetic practices and study. His numerous philosophical and theological works place him among the most distinguished writers of the Eastern church in the eighth century. His principal work is an exposition of 'the orthodox faith,' or Christian doctrines, in four books, which unites the two systems of scholastic and dogmatic theology, the former being by ratiocination, according to the Aristotelian or scholastic method, and the second by the authority of the Scriptures and the fathers. This work attained great reputation in the Greek church, and the author was styled Chrysorrhœas, or 'Golden-flowing,' on account of his eloquence. He promoted the study of Aristotle, and wrote various popular tracts, in which he collected and illustrated that philosopher's principles. He wrote also letters and treatises against heretics, especially against the Manichæans and Nestorians. His principal works have been published by Lequien, 'Opera J. Damasceni,' Paris and Venice, 1748, 2 vols. fol.

DAMASCE'NUS, NICOLA'US, a philosopher and historian of the age of Augustus, and the friend of Herod the Great, tetrarch of Judæa, is mentioned by Josephus, Athanasius, Eusebius, and others. He wrote various works in Greek, and among them one on universal history, in 144 books, of which we have some fragments, 'N. Damasceni Historiarum Excerpta et Fragmenta quæ supersunt,' 8vo., Leipzig, 1804; and again in Paris, 1805, edited by D. Coray.

DAMASCUS, a city of Syria, and the capital of an important Pashalik of Asiatic Turkey, is situated in a fertile plain at the east base of the Antilibanus ridge, about 180 miles south by west of Aleppo, in 33° 27' N. lat., and 36° 25' E. long. It is one of the most antient towns in the world, being mentioned as existing in the time of Abraham. (*Genesis* xiv. and xv.) Its antient name was Damesk, but the present natives call it Scham, which is also the name of Syria, and sometimes Scham Shereef, *i. e.*, 'the noble.' It is one of the very few places which have maintained a flourishing existence in all ages. Though often taken and devastated, it has always risen again, and has always been mentioned as one of the most delightful situations in the world. It appears to have been in the time of David or of Solomon (1 *Kings* xi., 24) the capital of an independent kingdom, which afterwards, under the name of the kingdom of Syria, was engaged in wars with the Jews. It was subsequently annexed to the empire of Assyria, afterwards to that of Persia; it then fell into the hands of the Macedonians, the Romans, and lastly of the Arabians, A.D. 634, when it was taken by the lieutenants of the caliph Abu-bekr after the defeat of the forces of the emperor Heraclius in its neighbourhood. It became for a time the residence of the caliphs, and after other vicissitudes was taken by the Turks under Sultan Selim. In the late war between the Porte and Mehemet Ali, pasha of Egypt, Damascus was taken by the troops of the latter, to whom it was formally ceded by the sultan by the peace of 1833. The Pashalik of Damascus extends from north to south, from Hamah on the Orontes down to the deserts of Arabia Petrea, south-east of the Dead Sea, a length of about four degrees of latitude; and it comprehends the country of Haouran, and the other districts on the east side of the Jordan and the Dead Sea, besides the greater part of Judæa west of the Jordan, including Jerusalem and Nablous. To the east it is bounded by deserts, which divide it from the valley of the Euphrates, to the north by the Pashalik of Aleppo, and to the west by the Pashalik of Acre.

The view of Damascus from the neighbouring mountain of Saleyeh, an offset of the Antilibanus to the north-west of the city, is very impressive; it comprises the town, with its numerous domes and minarets, the extensive woods, orchards, and gardens with which it is surrounded, clothed in perpetual verdure of various hues, and beyond it the vast level plain stretching to the east farther than the eye can reach, and bounded to the south-east by the distant mountains of Haouran. The river Barrady and other streams descending from the mountains furnish the city and the plain of Damascus with a constant supply of water, which is distributed into numerous canals for irrigation, and is

the main cause of the extraordinary fertility of the country. The town is about six miles in circumference, is surrounded by old brick walls falling to ruin in several places, and is said to contain, according to Buckingham and Richardson, about 150,000 inhabitants; but according to others above 200,000, of whom 12,000 are Christians, and about as many Jews. The rest are Mohammedan Syrians, Arabs, and Turks. The native Mohammedans have long had the reputation of being the most fanatical and intolerant in Turkey; but Dr. Richardson's account of them, and the reception which he and the rest of Lord Belmore's party met with, does not confirm this bad report of the Damascenes. (Richardson's *Travels along the Mediterranean and parts adjacent, in company with the Earl of Belmore, in 1816-18.*)

Seetzen, who visited Damascus in 1806, gave also rather a favourable account of the inhabitants. There is a Franciscan convent long established in the city, and the Greek patriarch of the church of Antioch usually resides there. When Dr. Richardson visited Damascus, Lord and Lady Belmore lodged at the French consul's, who appeared to live in perfect comfort and security in the midst of this fanatical population. A frightful insurrection however took place some years after, ostensibly on the news of an English consul coming to reside in the city, but the real source of the tumult appears to have been a long-brooding discontent at the weak and oppressive rule of the Porte and its pashas. Since that time, the pasha of Egypt and his son Ibrahim have enforced strict order and rational tolerance in Damascus, and the English consul-general and English merchants, in their Frank costume, live in and walk about the town in perfect safety. (Dr. Hogg, *Visit to Jerusalem, Alexandria, and Damascus*, 2 vols. 8vo., 1835; Michaud et Poujoulat, *Correspondance d'Orient*, 1833-35.) M. Poujoulat himself, who was much alarmed on entering the gates at hearing some fellow proposing to burn him as a Frank, yet honestly says, 'I could cite evidence greatly in favour of the Damascene Mussulmans. A Greek Catholic, who has had commercial relations with them for years, told me that he never had occasion to complain of them. I myself have frequently met Mussulmans in Christian houses, who treated me with great kindness. I cannot speak of the lower orders and the population of the suburbs, who probably resemble the same classes in most great cities.' The same writer gives the following statistical list:—'They reckon at Damascus 129 tanners' shops, 22 establishments for printing stuffs, 75 dyers of stuffs, 120 dyers of silk, 34 houses of silk-winders, 748 merchants of damask cloth, 211 grocers, 68 tobacco manufacturers, 72 saddlers, 11 tent merchants, 47 copper-smiths, 50 ironmongers, 54 farriers, 70 fur merchants, 98 lacemen, 24 corn-merchants, 148 bakers, 58 millers, 122 coffeehouses, 32 confectioners, 59 public baths, 129 butchers, 71 tailors, 43 shops for pipes, 6 watchmakers, 200 haberdashers' stores, 4 glass-manufactories, 19 armourers, 4 soap-factories, 143 weavers, and more than 400 public cooks.' The manufacture of Damascus blades, once so famous, has declined long since: but good sabres are still made. Saddles and bridles, both rich and highly finished; fine cabinet-work, inlaid with ivory and mother-of-pearl, and rich jewellery, are among the articles of Damascene industry. 'The shopkeepers of Damascus,' says Dr. Richardson, 'are generally clean and well-dressed, very comfortable in their appearance, and extremely civil to strangers. The bazaars are better lighted, and have a more elegant appearance than those of Cairo or Constantinople. Every class of commodities has its own street or bazaar: in one they sell nothing but shoes, another is occupied by the goldsmiths,' &c. The town is well supplied with ice; and ice-water, mixed with the juice of figs or currants, is sold and drank in profusion. The best coffeehouses of Damascus are situated in the skirts of the town, on the edge of that branch of the river Barrady which supplies the gardens; they are built of wood, and are cool and well shaded from the sun, which is their chief attraction. The streets are narrow, and many of them have a gloomy dilapidated appearance, being lined by dead brick-walls, with small mean-looking doors here and there, which open into the courts of the respective houses, which are not seen from the streets. Many of these houses are splendid in their interior, the courts being paved with marble and refreshed by fountains, with arcades and divans around. There are no carriages at Damascus, and but few carts; camels, horses, mules, and donkeys constituting the means of carriage or conveyance. The great khan is a sumptuous building, the masonry being formed of alternate layers of

black and white marble, like the Florence cathedral. The spacious square court within has a handsome fountain in the middle, and is surrounded by a fine arcade of pointed arches, enriched with mouldings. On the ground-floor are the entrances to chambers and magazines, and a staircase and gallery lead to another series of apartments above. The principal mosque is also a fine building: it was originally a Christian temple of the Corinthian order, said to have been built by the Emperor Heraclius. There is also an extensive citadel.

Beirut is considered as the port of Damascus. The exports from Damascus are chiefly raw silk, galls, madder, gums, opium, and dried fruit; but Damascus is also a great place of depôt and market of goods both from India and from Europe. The great Hadji caravan goes every year from Damascus to Mecca. Other caravans proceed to Aleppo, to Hit on the Euphrates, and thence to Bagdad. From Damascus to Hit is about eleven caravan days.

[Coin of Damascus. Imperial Greek.]

British Museum. Actual size. Copper. Weight, 217½ grains.

DAMASK, a description of woven cloths composed both of flax and of silk, which are believed to have been originally brought from Damascus. Linen damask is used for table-cloths and napkins. Until the last half century the cloths of this kind used in England were imported from Germany, but the manufacture has since that time been successfully carried on both in Scotland and in Ireland. Damask cloths are of thick texture but fine in quality, and the weaving of them puts into requisition all the skill of the weaver for the production of the elaborate patterns which they bear. Some of these patterns require upwards of 1200 changes of the draw-loom for their completion, the method of performing which could not be explained without going into the detail of the art of weaving. The weaving of silk damask was introduced into England by the Flemish weavers, who fled hither from the persecutions of the duke of Alva in 1567. For a long time silk damask dresses were used on all occasions of ceremony by ladies of rank and by wealthy commoners, but they were never commonly worn. They were wrought with a great variety of colours, and if the patterns did not exhibit much taste they were sufficiently showy: from the quantity of silk which they contained they were also very costly. The damask employed at the present day for curtains and the like articles of household furniture is made of a mixture of silk with flax, cotton, or wool; the warp is of the more costly material.

DAMASUS I., the son of a presbyter, was elected bishop of Rome after the death of Liberius, A.D. 366. A party among the clergy elected the deacon Ursinus in opposition to Damasus, and the people, who had then a share in the elections, being equally divided, the two parties fought in the streets and in the churches for several days. Ammianus Marcellinus (xxvii. 3), who gives an account of these disorders, states that 137 bodies of the slain were found in one day in the basilica of Sicinius alone. The same author draws a sad picture of the corruption of the clergy of Rome in that age, of their cupidity and luxury, which he contrasts with the modest bearing of some of the provincial clergy. In the Theodosian Code (b. xx.) there is an imperial constitution, which was issued about that time for the better discipline of the clergy, in which they are forbidden receiving legacies from widows and minors, frequenting the houses of matrons, cohabiting with women under the pretence of religion, &c. Damasus being acknowledged by the bishops of Italy, was confirmed by the Emperor Valentinian, who sent Ursinus into exile. The party of the latter however kept up disturbances in Italy for several years. Ursinus himself returned to Italy. A Jew having brought a charge of adultery against Damasus, the affair was tried by a council of bishops at Rome in 378, and Damasus was acquitted. The Emperor Gratian being appealed to, sent

the Jew into exile, as well as Ursinus and several of his party.

Damasus held several councils for the purpose of condemning heretics, and especially the Arians, the Apollinarians, and the Luciferians. He also was requested by the Eastern churches to decide disputes which had arisen among them, particularly on the subject of the election of Flavianus to the see of Antioch. Among the eastern bishops who repaired to Rome on that occasion was Epiphanius, bishop of Cyprus, accompanied by St. Jerome, who had acquired, during his residence in Syria and Palestine, a great reputation for theological learning. Jerome became intimate with Damasus, and is said to have acted as his secretary. It was not until the death of Damasus, A.D. 384, that Jerome finally returned to the East, where he died.

There are a few letters of Damasus which have been preserved by Theodoretus and St. Jerome. Other letters and verses, as well as a liber pontificalis, which have been published under his name, are now considered apocryphal. The church of S. Lorenzo in Damaso at Rome has derived its name from him, as he is believed to have been the founder of a church on the spot where the present structure stands, and where he was buried. Damasus was one of the most learned and influential among the earlier bishops of Rome. He was succeeded by Syricius.

DAMASUS II., Poppo, bishop of Brixen, was elected pope A.D. 1048, in the room of Benedict IX., who had been deposed by the council of Sutri for his misconduct. He died, twenty-three days after his election, at Palestrina, and was succeeded by Leo IX.

DAMAUN, a district of Afghanistan, formerly subject to the sovereign of Cabul, and now divided among many small uncivilized tribes, who are frequently engaged in quarrels with each other. Damaun extends along the west bank of the Indus between 31° and 33° N. lat. and includes the tract of country comprehended between the Salt range, the Soliman range, the Indus, and Sungur in Upper Sinde. This district consists almost wholly of plains, and great part of the soil is sandy and sterile, the natural unproductiveness being suffered to remain without any attempt to remedy it, on account of the insecure condition of the inhabitants. The land in the immediate vicinity of the villages is, however, cultivated and rendered productive. The only trees to be found in the district are some dates which have been planted in these spots. The country is very thinly populated. Dera-Ishmael-Khan, the capital of the district, stands on the west bank of the Indus, in 31° 50' N. lat., and 70° 33' E. long., and is enclosed by a wall of unburnt bricks about a mile and a half in circumference. The greater part of the inhabitants are Baloochees; the remainder are composed of Hindus, Afghans, and Juts. The country people of Damaun are chiefly Juts and Baloochees; they are dark-complexioned, and a meagre ill-formed race. The banks of the river are covered in many parts with thick jungle, which is the resort of numerous wild animals. The climate is subject to great changes. In the winter, frost is very common in the night and morning, when the thermometer is often some degrees below the freezing point. The summer is insupportably hot both by day and by night, and it is said that the inhabitants are obliged to wet their clothes and thus produce an artificial coolness in order to procure any sleep.

DAMIE'NS, ROBERT FRANÇOIS, was born in 1715, in a village of Artois, where his father had a small farm. He enlisted in the army, which he left at the peace, and went to Paris, where he engaged as a menial, first in the College of the Jesuits, and afterwards in several families: he was repeatedly turned out of his situation on account of misconduct. While he was unemployed he used to attend the great hall of the Palace of Justice, which was then the rendezvous of those who were styled Jansenists. At that time France was distracted by the long quarrel concerning the bull Unigenitus. [CLEMENT XI.] The parliament of Paris disapproved of the bull, although it had been forced by the court to register it. Several of the parish clergy expressed a similar opinion, and were on that account suspended from their functions by their bishops, who were in general favourable to the prerogatives of the court of Rome. The clergymen thus laid under interdict appealed to the parliament, which returned a decision favourable to them. Upon this the court and the bishops attacked the parliament, several of whose members were imprisoned by lettres de cachet. The supposed miracles

of the Abbé Paris, brother of a councillor of parliament, and a sturdy opposer of the bull, excited the minds of the people, and created a sect of fanatics, called 'convulsionnaires,' or 'shakers.' The archbishop of Paris refused the sacraments, not only to the shakers, but to all those suspected of Jansenism, that is to say, opposed to the bull. The parliament issued arrêts to oblige the local clergy to administer the sacraments. The king cashiered these arrêts. The outcry now became general against the archbishop, the ministers, and the king; France was threatened with a schism and a war of religion. Louis XV. had then for his mistress Madame de Pompadour, who was generally disliked on account of her haughtiness and prodigality. All these complaints seem to have made a deep though confused impression on the excitable but ignorant mind of Damiens. Gautier, a servant of one of the councillors of parliament, acknowledged that he had heard him speak very violently in defence of the parliament, and against the archbishop of Paris. It would seem that Damiens was particularly irritated at the archbishop refusing the sacraments to so many people, and that he fancied that by killing or at least wounding the king he would effect a change in the system of the government, and put down the archbishop and his party. However this may be, Damiens went to Versailles; and on the 5th of January, 1757, about five in the afternoon, as Louis was stepping into his carriage, Damiens, who had made his way unobserved among the attendants, stabbed him on the right side with a knife. The wound was slight, and the king, after a few days, recovered. It is worthy of remark, that the knife had two blades, of which Damiens used the shorter, which seems to confirm what he stated on his interrogatory, that he did not intend to kill the king, but only to frighten him and give him a warning. He did not attempt to run away, but was secured, examined, and put to the torture. He was afterwards removed to Paris, and committed for trial before the grande chambre of the parliament, to which the king wrote, or was made to write by his ministers, a letter, in which he demanded 'a signal vengeance.' Damiens was condemned as a regicide to be broken alive by four horses. The sentence was executed on the 28th of March, 1757, on the Place de Grève. Before being put to death, he was tortured for one hour and a half on the place of execution with red-hot pincers, molten lead, and other cruel contrivances. All the windows and roofs of the houses around were filled with spectators, men and women, among whom were many ladies of rank. It was altogether one of the most disgraceful exhibitions that ever took place in a civilized country.

Damiens acknowledged no accomplices, and it does not appear that he had any. His crime was the act of a weak and disordered mind. His trial was published by Le Breton, with a notice of his life, 4to. 1757. (See also *Histoire du Parlement de Paris*, 8vo. 1769.)

DAMIETTA or **DAMIA'T**, a town of Lower Egypt, on the right or east bank of one of the principal branches of the Nile, and about six miles above its mouth, the antient Phatniticum Ostium. Old Damietta, or Thamiatis as it was called under the Byzantine emperors, stood about four miles farther north, and near the sea, which however has now receded from it: its scanty remains are seen near the village of Esbé, about two miles from the shore. Thamiatis was a small town in the time of Stephanus Byzantinus, but it increased gradually from the decay of Pelusium, and drew to itself the trade of the latter. It was taken by the Saracens, who surrounded it with strong walls and made it one of the most commercial and wealthy towns of Egypt. Roger, king of Sicily, took it, but it was retaken by Salaheddin; it was taken again by the crusaders under John of Brienne, but they lost it soon after. In 1249 Louis IX. landed with a large armament, and took Thamiatis almost without resistance; but having advanced inland, he was defeated and taken prisoner at Mansoura. The sultans of Egypt, in order to prevent further attacks in that quarter, choked up the mouth of the Nile by sinking large barges filled with stones, and thus formed a dangerous bar, which prevents large vessels from entering the river. They also razed Thamiatis to the ground, and removed the inhabitants farther inland. From these occurrences arose New Damietta.

The town of Damietta is larger than Rosetta: its population amounts to about 20,000, although several travellers have reckoned it much higher. It has some fine mosques,

several bazars, and baths adorned with marble; many of the houses have pavilions or belvederes on the terraces for enjoying the cool breeze. It carries on a considerable trade both with Europe and the Levant. The merchant-ships remain at anchor outside of the bar, and load and unload by means of djermes or boats. Rice is one of the chief articles of exportation. At Damietta and in the neighbourhood are manufactures of fine cotton cloth, towels, &c. The country around is a complete garden, irrigated by numerous canals, and planted with all kinds of fruit-trees, such as orange, lemon, fig, tamarind, pomegranate, &c. The great marshy lake Menzaleh begins two or three miles east of Damietta, and extends about 40 miles in length to near antient Pelusium. It communicates with the sea by several mouths, and with the Damietta branch of the Nile by canals. The fishery of lake Menzaleh is very abundant; various kinds of water-fowl are also caught upon it.

Damietta is the head town of a prefectship or province, which extends eastwards along the banks of lake Menzaleh as far as El Arish on the borders of the Syrian desert.

DAMP, CHOKE. [MINING.]

DAMPIER, WILLIAM, was born in 1652, of a Somersetshire family; he went early to sea, served in the war against the Dutch, and afterwards became overseer of a plantation in Jamaica. He thence went to the Bay of Campeachy with other log-wood cutters, and remained there several years. He kept a journal of his adventures and observations on that coast, which was afterwards published; 'Voyages to the Bay of Campeachy,' London, 1729, with a 'Treatise on Winds and Tides.' Dampier, besides being a bold seaman, had also studied navigation as a science. In 1679 he joined a party of buccaneers, with whom he crossed the Isthmus of Darien, and having embarked in canoes and other small craft on the Pacific ocean, they captured several Spanish vessels, in which they cruised along the coast of Spanish America, waging a war of extermination both by sea and land against the subjects of Spain. [BUCCANEERS.] In 1684 Dampier sailed again from Virginia with another expedition, which doubled Cape Horn and cruised along the coasts of Chile, Peru, and Mexico, making depredations upon the Spaniards. From the coast of Mexico they steered for the East Indies, touched at New Holland, and after several adventures in the Indian Seas, Dampier went on shore at Bencoolen, from whence he found his way back to England in 1691, when he published his 'Voyage round the World,' a most interesting account, and which attracted considerable attention. His abilities becoming known, he was appointed commander of a sloop of war in the king's service, and was sent on a voyage of discovery to the South Seas. Dampier explored the west and north-west coasts of New Holland, surveyed Shark's Bay, and gave his name to a small archipelago east of North-West Cape. He also explored the coasts of New Guinea, New Britain, and New Ireland, and gave his name to the straits which separate the two former; on his homeward voyage he was wrecked on the Isle of Ascension. He at last returned to England in 1701, when he published the account of this voyage. In 1707 he published a 'Vindication of his Voyage to the South Seas in the ship St. George,' with which he had sailed from Virginia in his former marauding expedition. Dampier went to sea again till 1711, but the particulars of the latter part of his life are little known. He ranks among the most enterprising navigators of England. He was acquainted with botany, and was possessed of considerable information and general knowledge. His style of narrative is vivid, and bears the marks of truth. His voyages were published together in 3 vols. 8vo., London, 1697—1709.

DAMSON, or **DAMASCENE** (from Damascus), a race of plums cultivated in this country for the sake of their hardness and prolific habits. They are a mere form of the domestic plum, from which there are no certain characters to distinguish them, except the abundance of their late oval fruit, and the property they possess of propagating by suckers. All the varieties are used for kitchen purposes principally, and are generally confined to the gardens of cottages or farm-houses, where the quantity of produce is more valued than its quality. Much the finest variety of this sort of plum is that called the Shropshire damson, which is extensively multiplied in the nurseries by grafting.

DANCING. [BALLET.]

DANCOURT, FLORENT CARTON, a popular French

dramatist and actor of the times of Louis XIV., was born in 1661, and studied at Paris under the Jesuit Larue. His preceptor, observing that his talents were far from ordinary, wished him to devote himself to the religious profession, but Dancourt preferred the law, and acquired some reputation as an advocate. He shortly however fell in love with the daughter of the comedian, La Thorilière, an attachment which induced him to quit his legal studies and appear on the stage. Having married Mlle. La Thorilière, he became one of the king's comedians, and even one of his greatest favourites. An anecdote is told of his being saved from falling by Louis, who caught his shoulder; and in the days when this story was current, a king who under any circumstances put forth his hand towards a subject was reckoned full as condescending as one of the gods of antiquity who came down to aid some favourite hero. After remaining thirty-eight years in the service of the king, he retired to his estate at Berri, where he passed the remainder of his life in devotional exercises, and wrote some psalms and a sacred tragedy, which is not extant. He died in 1726, having superintended the erection of his own tomb, leaving two daughters, who were both actresses, and both married into families of distinction.

The works of this author occupy six volumes: they were most of them successful at the time they were written. The greater number of them are farces, the scene of which lies mostly in low life. There is a drollery about them and a smartness in the dialogue which will always render them amusing, but the interest they possessed at the time of their appearance is now lost. Dancourt being an unlearned man, sought for subjects among incidents which he himself witnessed, and which were often well known to the public. An author whose chief excellence lies in happily delineating events of a local interest may be sure of popularity, but equally sure that his popularity will be but transient.

DANDELION, a corruption of the French name 'dent de lion,' or lion's tooth, a common weed, with a tapering milky perennial root, resembling that of succory: like the latter, it is sometimes cut into pieces, roasted, and employed to adulterate coffee. Its leaves have also been forced in the winter as salad; but its excessive bitterness prevents its being much employed in this way. It is the *Leontodon Taraxacum* of botanists.

DA'NDOLO, ENRICO, a patrician of Venice, who was elected doge in 1192 at a very advanced age. In the year 1201 the French crusaders applied to the Venetian senate for assistance in their expedition to Palestine. Dandolo warmly supported their petition, lent them money and provisions and ships, and stipulated in return that they should assist him in conquering the town of Zara for the republic. Dandolo, though aged and nearly blind, embarked in the admiral's ship. The crusaders took Zara, and afterwards, being invited by Alexius, son of Isaac Angelus, who had been driven from the throne of Constantinople, the Venetians and crusaders, forgetting the Holy Land, sailed for Constantinople, attacked it and took it by storm, A.D. 1204. Old Dandolo, then nearly 90 years of age, was the soul of this expedition; he was one of the first to land, on the first attack in 1203, and to take possession of part of the ramparts, on which he planted the standard of St. Mark. For other particulars of this expedition and its results, see BALDWIN I., Emperor of Constantinople. Dandolo refused the imperial crown, which the crusaders had offered to him, but accepted the title of Despot of Romania. He died shortly after, in 1205, and was buried in the church of Santa Sophia. Dandolo is one of those who contributed most to the establishment of the maritime power of Venice. There have been other senators and doges of the same name.

DANEGELD, sometimes called simply the GELD, was a tax originally imposed in order to purchase peace with the Danes; and means Danish payment. Henry says (*Hist. of Brit.*, edit. 8vo., Lond., 1805, vol. iii., p. 366,) that when the invasions of the Danes were frequent and formidable, it became a custom sometimes to bribe them with a sum of money to desist from their depredations and leave the country; and at other times to keep a considerable body of troops in constant pay to defend the coasts against these dangerous enemies. The ordinary revenues of the crown were quite inadequate to the expense of these expedients; and therefore it was found necessary, with the consent of the wittenagemot, to impose a tax first of one Saxon shil-

ling, and afterwards of two or more shillings, on every hide of land in the kingdom. As there were 243,600 hides of land in England, this tax, at one shilling on each hide, raised 12,180 Saxon pounds, equal in quantity of silver to about 36,540*l.* sterling, and in efficacy to more than 360,000*l.* of our money at present. According to the Saxon Chronicle (edit. Gibs., p. 116), this tax was first imposed A.D. 991. It was soon after raised to two and at last to seven shillings on every hide of land, and continued to be levied long after the original occasion of imposing it had ceased.

Whilst the invasions of the Danes were almost annual, our kings derived little profit from this tax, which was all expended in bribing or fighting these invaders; but after the accession of the Danish princes to the throne of England, it became one of the chief branches of the royal revenue. This tax was raised so high, and collected with so much severity by King Canute, A.D. 1018, that it amounted to the prodigious sum of 71,000*l.*, beside 11,000*l.* paid by the city of London. (*Chron. Sax.*, ut supr., p. 151.)

Edward the Confessor, who succeeded Hardicnut in 1042, and put a stop to all future payments from the English to the Danes, as well tributary as stipendiary, continued nevertheless to collect danegeld from the subject until the year 1051, when, as Ingulphus and other authors say, he absolutely repealed it. It was revived at an early period of William the Conqueror's reign, and, according to Webb, in his 'Short Account of Danegeld,' 4to., Lond., 1756, p. 2, continued to be collected as low as 21 Hen. II., if not later. In the Domesday Survey, danegeld occurs but once by its own name, tom. i., fol. 336 b., under Stamford, in Lincolnshire. It is mentioned as one of the *Jura regalia* in the Laws of Henry I., chap. 10. Stephen, at his coronation, took an oath that he would remit this tax. (Compare Spelman's and Du Cange's *Glossaries*, v. 'Danigeldum.')

DANES is the general appellation given to the Scandinavian tribes which in the ninth and tenth centuries became so formidable by their predatory expeditions, and invaded and occupied a great part of Britain and France. The early history of the Scandinavian nations is involved in great obscurity, though Danish and Swedish chroniclers gravely deduce their genealogy from Japhet and his son Gog, and relate their early migration from Asia. But coming to more historical times, there is a poem on the exploits of the Danes in the third and fourth centuries, which refers to their wars among themselves, and in which the Danes, properly so called, or Western Danes, appear as the inhabitants of Jutia, who are also called Scyldingi; while the Sveones (perhaps the same as the Suiones), mentioned by Tacitus (*German.*) as living near the shores of the Baltic, are called also Eastern Danes, or inhabitants of part of the country now called Sweden. Next to these are mentioned the Geata, or Goths; and in the islands of the Baltic, the Sæ Geata, or Sea Goths, called also Scyl'ingi. We find also mention of the Northern Danes, probably the Norwegians. (*De Danorum Rebus gestis Seculis III. et IV. Poema Danicum dialecto Anglo-Saxonica ex bibliotheca Cottoniana Musæi Britannici*, edited by G. J. Thorkelein, 4to. 1815.) The common language of all these people was the Norse or Dönsk Tunga, which is still spoken in Iceland, and of which the Anglo-Saxon was a dialect. (P. Vidalini, *De Appellatione Linguae Septentrionalis*, 1775.)

Scandinavian migrations had taken place to North Britain in very remote times; and it appears probable that some of the tribes which inhabited Caledonia in the Roman period had come originally from that quarter. The Jutes and Angli, who, with the Saxons, conquered Britain, came from Jutia, the country of the Western Danes. But after the Saxon conquest, the connexion between the migrated tribes and the Danes who had remained in Scandinavia became obliterated, until the end of the eighth century, when the Danes began to make war upon their old kinsmen with all the fierceness of inveterate enemies. Their predatory descents on the coast of Britain became formidable during the reign of Egbert; and under his successors the Danes obtained possession of great part of the island, until Alfred the Great defeated them, and obliged the Danish chieftains to submit. [ALFRED.] The eastern part of England retained long after the name of Danelagh, or Danish Law, and the population was in great measure of Danish stock, especially to the north of the Humber. After the death of Alfred fresh incursions took

place, until at the beginning of the eleventh century Canute, or Knut, having established himself as sovereign of all the Scandinavian nations, added Britain also by conquest to his sceptre. [CANUTE.] After Canute's death his successors Harold and Hardicnut held the sway of Britain for a few years longer, after which the line of the Saxon kings was restored in the person of Edward the Confessor. The Norman conquest, which followed close upon the death of the latter, put an end to the Danish invasions on the coasts of Britain. But the Normans themselves were originally of Danish stock in the general sense of the name, having settled in North France under Rollo the Ganger in Alfred's time; and those Norman pilgrims and knights who conquered the kingdoms of Sicily and Apulia in the eleventh century were likewise their progeny.

DANIEL, one of the four greater prophets (Isaiah, Jeremiah, Ezekiel, Daniel). From the first chapter of the book of this prophet we learn that he was of the tribe of Judah; that, when a child, he was carried captive to Babylon by Nebuchadnezzar, in the third year of the reign of Jehoiakim, king of Judah, 606 B.C., and that he was one of the 'children (ver. 4) in whom was no blemish, but well-favoured, and skilful in all wisdom, and cunning in knowledge, and understanding science,' who were chosen by the master of the king of Babylon's eunuchs to be taught 'the learning and the tongue of the Chaldeans,' and to stand before the king. It appears to have been required of these children to have countenances fair and fat in flesh—qualities in which Daniel, otherwise Belteshazzar, and his three companions, Shadrach, Meshach, and Abednego excelled, by adopting a diet of pulse and water instead of the king's meat and wine supplied to them for this purpose (10, 15). 'Daniel had understanding in all visions and dreams; and in all matters of wisdom and understanding the king found him and his three companions ten times better than all the magicians and astrologers that were in all his realm' (17, 20). In reward for the interpretation of a dream related in ch. 2, 'King Nebuchadnezzar not only gave Daniel many valuable gifts, and made him ruler over the whole province of Babylon, and chief of the governors over all the wise men of Babylon, but he fell upon his face and worshipped him, and commanded an oblation and sweet odours to be offered unto him' (46, 48). Daniel's Chaldean name of Belteshazzar was that of a Babylonian deity, the god of Nebuchadnezzar; and the prophet is repeatedly said to have possessed the spirit of the holy gods, and to have been made master of the magicians, astrologers, Chaldeans, and soothsayers (iv., 8, 9; v., 11). For interpreting the mysterious writing on the wall, king Belshazzar clothed him in scarlet, put a chain of gold about his neck, and made him third ruler in the kingdom. Daniel also prospered in the reign of the Median monarch Darius (probably the Cyaxares of the Greek historians), who appointed him the first of three presidents over 120 princes, whom he set over the whole kingdom (vi., 2). Having escaped unhurt from the lions' den into which he was thrown by Darius, he continued to prosper in the reign of Cyrus the Persian (28). He did not return to Judæa on the termination of the captivity, but remained with the large portion of his countrymen who continued at Babylon, where he is generally supposed to have died. Some, however, state that he died at Susa, on the Eulæus. He was contemporary with Ezekiel (xiv. 14, 20, and xxviii. 3). Among the Rabbis it is generally maintained that Daniel was not a true prophet; that he did not dwell in the Holy Land, out of which they say the spirit of prophecy does not reside; that he spent his life, not as the other Jewish prophets, in solitude, poverty, and abstinence, but amid the grandeur, pomp, and luxury of a royal palace; that he was a eunuch (2 Kings, xx. 18), one of a class who are excluded from the congregation of the Lord (Deut. xxiii. 1). Some place his writings among the mere Hagiographia, as having less authority than the canonical books. They account for the fact of his not being mentioned when his three companions were cast into the furnace, by saying that he was absent from Babylon on an expedition to Egypt, for the purpose of stealing hogs (Calmet's *Dict. of the Bible*); and they object to his prophecies that they all relate to dreams and visions, which they consider the most imperfect modes of revelation. However, it is said by Josephus (*Ant. Jud.* l. x. c. 12), that Daniel was a great and true prophet, who was favoured

with communications from Jehovah: he says also that Daniel built a famous palace at Susa or Ecbatana. Dr. Adam Clarke and others think that Zoroaster was Daniel. The twelve chapters of the canonical book of Daniel are partly in the Hebrew and partly in the Chaldaic language. The uncanonical or apocryphal books attributed to this prophet, consisting of the stories of Susannah and Bel and the Dragon, and the Song of the Three Children, are extant only in the Greek of Theodotian, which is adopted in all the Greek churches of the east, the version of the Septuagint being lost. The following are the principal prophetic subjects of the canonical book of Daniel. Chapter 2 contains the account of Nebuchadnezzar's dream of the great image of gold, silver, brass, iron, and clay, with Daniel's interpretation. The stone which became a great mountain is considered as prophetic of the Messiah. Chapter 4 relates the same monarch's dream of the great tree, representing himself, as interpreted by Daniel, and which was speedily fulfilled. In chapter 5 is recounted Daniel's interpretation of the writing on the wall at the feast of Belshazzar. Chapter 7 contains the prophet's description and interpretation of his own dream of the four great beasts. The commentators state that the four kingdoms of the earth designed by these four beasts were the Babylonian, the Medo-Persian, the Macedo-Grecian, and the Roman. The ten horns of the fourth beast are said to be ten kingdoms rising out of the Roman empire; but what particular kingdoms are meant appears rather difficult to determine, if we may judge from the conflicting opinions of different writers. The Rev. Hartwell Horne, in his 'Introduction to the Bible,' has tabulated the theories of some of the most eminent commentators, which exhibit scarcely a single instance of agreement in any particular. Thus, in explaining the meaning of the first horn, Machiavel applies it to the Ostrogoths, Dr. Mede to the Britons, Drs. Lloyd and Hales to the Huns, Sir Isaac Newton to the Vandals, and Bishop Newton to the senate of Rome. This dream has always been much insisted on by Protestant writers as a prophecy relating to the destinies of the Church of Rome. Daniel's vision of the ram and the he-goat described in Chapter 8 is considered to signify the destruction of the Medo-Persian empire by the Macedonians, who were antiently called *Ægadæ*, or *Ægeatæ*, that is, the goat-people. The prophecy of the seventy weeks, communicated to Daniel by the angel called the man Gabriel in chapter 9, is regarded by all Christians as a striking prediction of the advent of Jesus as the Messiah. Sir Isaac Newton, in his Commentary on Daniel, declares it to be the foundation of the Christian religion. The weeks are understood as being prophetic weeks, consisting each of seven years. (*Leviticus*, xxv. 8.) No scriptural authority is to be found for this interpretation (Le Clerc, *Biblioth.* tom. xv. p. 201); but an instance of this mode of reckoning occurs in Macrobius, *Somn. Scip.*, l. i. c. 6. In the 25th and 26th verses it is said that from the first year of the reign of Darius (ver. 1, 3, 23) unto the Messiah the prince would be 69 weeks, or 483 years, and that then Messiah would be cut off, which disagrees with the best chronologists, who make the first year of Darius 538 B.C. (A. Clarke's *Bib.*) The chronological difficulties of this important prophecy have occasioned a great variety of interpretations, and exercised the pens of the most learned of the fathers and of modern divines. (*Improved Version of Daniel*, by the Rev. Thos. Wintle, 8vo. 1836; Prideaux's *Connect.* vol. i. p. 306; Vossius, *De 70 Hebdomad. Dan.*, p. 183). In the 10th and 11th chapters other visions are described which relate chiefly to the conquests and revolutions of several Asiatic nations. The prophecy in the 12th and last chapter extends to the end of time, and speaks of the resurrection and the day of judgment. In the time of Jerome some few Rabbis admitted the story of Susannah as canonical, while others rejected it as such; and Josephus, in speaking of Daniel, says nothing either of Susannah or of Bel and the Dragon. (Hieronymus, *In Dan.*) A learned dissertation on these books is given by Eichhorn in his 'Einleitung in die Apokriphischen Schriften,' p. 419. Porphyry, in the twelfth of his fifteen books against the Christians, impugns the genuineness and authority of the prophecies of Daniel, contending that they are falsely ascribed to him, and that they are really historical, and were written after the occurrence of the events to which they relate. Dr. N. Lardner has collected some of these objections, and accompanied

them with the replies of Jerome (Lardner's *Works*, vol. viii. pp. 185-204). Bishop Chandler, in his 'Vindication of the Defence of Christianity,' and Dr. Samuel Chandler, in a 'Vindication of the Prophecies of Daniel,' have elaborately discussed the subject of the genuineness and canonical authority of this prophetic book. It is remarked by Mr. Horne, that 'Of all the old prophets Daniel is the easiest to be understood;' and that 'he writes more like an historian than a prophet.' Grotius, Le Clerc, and several other learned critics, have maintained that all the prophecies of Daniel relate to and terminated in the persecution of the Jews under Antiochus Epiphanes, in the age succeeding that of the prophet. In Mr. Horne's 'Introduction,' vol. ii. p. 792-3, an account is given of the principal commentators on Daniel, as Sir Isaac and Bishop Newton, Drs. Faber, Frere, Hales, &c., and of the numerous disquisitions on the particular prophecies, especially that of the seventy weeks. The commentary of Sir Isaac Newton is viewed by the divines who have written on Daniel in very different lights; some have bestowed on it the highest commendation, and others have treated it as of little or no value. Numerous sermons on texts, and commentaries on the book of Daniel, are named in the 'Bibliotheca Britannica' by Watts. (See Eichhorn's *Einleitung in das Alte Testament*, vol. iii. p. 382; *Preface to and Comment. on Dan.* in Dr. Adam Clarke's *Bible*, especially on chaps. ii. vii. and ix.; Prideaux's *Connect.*, vol. ii. p. 380; *Daniel's Seventy Weeks Interpreted by a Layman*, 8vo. 1836.)

DANIEL, SAMUEL, was born in Somersetshire, A.D. 1562, and educated at Magdalen Hall, Oxford, which, however, he left without a degree, 'his geny being,' according to Anthony à Wood, 'more prone to easier and smoother subjects than in pecking and hewing at logic.' He became tutor to Lady Anne Clifford, subsequently Countess of Pembroke, and was afterwards groom of the privy chamber to Anne, queen of James I. He is said to have been poet-laureat on Spenser's death; but it is more likely that he was only one of many employed about the court in writing masques and birth-day odes, and in this capacity he seems to have stirred the wrath of Ben Jonson, who probably held him in the light of a rival. Towards the end of his life he retired into Somersetshire, where he died in 1619. His will is preserved in the Prerogative-court at Canterbury, and in Rymer's *Fœdera* exists a patent granting him the exclusive printing of his 'History of England' for the term of ten years.

His poems consist of an Heroic, in six books, on the Wars of York and Lancaster: it contains many stanzas in his best style, which unite such grace of language with sweetness of thought as to render them much more intelligible at present than those of his contemporary Spenser.

Daniel partly conformed to the fashion then prevailing, which consisted in a mode of expression termed euphuism, so well known by the specimen given in 'Kenilworth;' but a perusal of his works will show that, of the numerous Latinized words which the revival of learning introduced into our tongue, his good taste prompted him to choose, with very few exceptions, those which are at present in use; that is, he only admitted those which were really necessary to complete the language. The poem next in length is 'Musophilus,' a dialogue between Musophilus and Philocosmus. It is, we think, his master-piece both in thought and execution; the somewhat irregular terza rima in which it is written seems well adapted for a union of sweetness and continuity of thought. It contains an apology for literary pursuits, against the objections urged by a man of the world, and might be applied with equal force at present; indeed the last couplet of the passage with which the poem opens seems far more applicable to the nineteenth century than to the sixteenth. The orthography is modernized in the following extract:—

Fond man, Musophilus, that thus dost spend,
In an ungrateful art, thy dearest days,
Tiring thy wits, and toiling to no end,
But to attain that idle smoke of praise;
Now, when this busy world cannot attend
The untimely music of neglected lays;
Other delights than these, other desires,
This wiser profit-seeking age requires.'

The other poems contained in the edition of 1602 are, a letter from Octavia to Mark Antony, which shows to a striking extent that faculty peculiar to a true poet, which has been called 'dramatic power;*' 'The Tragedy of Cleopatra,' in alternate rhymes, with chorusses on the antique

* It would perhaps be better understood by the words 'power of identification,' by which the poet speaks naturally in any character.

model; and 'The Complaint of Rosamond,' who speaks from the infernal regions, but is little encumbered by classical imagery after the first few sentences; this poem is written in a seven-line stanza, of which the first and third, the second, fourth, and fifth, and the two last, rhyme; and contains much beautiful description as well as tender thought, introducing sensuous imagery without the least approach to indelicacy or impurity; indeed the whole character of his poems quite justifies the somewhat quaint assertion of old Fuller, that 'he carried in his Christian and surname two holy prophets, his monitors, so to qualify his raptures that he abhorred all profaneness.' Besides these poems, are 57 sonnets to Delia, several masques, odes, and epistles. His prose works are, 'A History of England, in two parts, extending to the reign of Ed. III.,' and 'An Apology for Rhyme,' which last shows a close acquaintance with the rules and niceties of his art, and contains several remarks on rhythm, interesting in illustration of the change in pronunciation which had taken place since Chaucer. It also shows, what is somewhat strange, that he considered rhyming tragedies the rule, and those in blank verse the exception; at least such seems the only meaning his words will bear: he says, 'I think a tragedy would indeed best comport with a blank verse and dispense with rhymes,' which is very unaccountable, unless we suppose him to have referred to tragedy on the antique model alone, for to attribute to him Dryden's ignorance on the subject of our early literature would be absurd. On the whole, whether as a poet or a prose writer, he has been most undeservedly neglected. In our judgment, he fully merits Southey's encomium—'Thoughtful, grateful, right-minded, and gentle-hearted, there is no poet in any language of whom it may be inferred with more certainty from his writings that he was an amiable and wise and good man.' (Southey's *British Poets*; Wood's *Athen. Oxon.*; Fuller's *Worthies*; and the *Biographia Britannica*.)

DANIEL, LE PE'RE, a Jesuit, born at Rouen in 1649, wrote the history of France from the commencement of the monarchy, 3 vols., fol., 1713, which he dedicated to Louis XIV., who made him historiographer of the kingdom, with a pension of 2000 francs. The most valuable part of his history is that which relates to the reigns previous to Louis XI., and he is more correct with regard to facts than Mézerai. But the work altogether is very imperfect: the author says little concerning the state of society: it is a history of the kings rather than of the people. He enters very largely into religious controversies, and is very intolerant towards those whom he considers heterodox. His style also is feeble and uninteresting. The best edition of his history is that in 17 vols., 4to., Paris, 1755-60, with considerable additions by Father Griffet. The other works of Père Daniel are;—1, 'Observations critiques sur l'Histoire de France écrite par Mézerai,' in which he endeavours to throw discredit on the rival historian, who, although often inexact, is upon the whole more liberal-minded than Daniël, for which reason he lost his pension. [COLBERT.] Both their histories, however, have been superseded by the better one of Velly and Villaret, 1759. 2, 'Histoire de la Milice Française,' exhibiting the changes that had taken place in the French military establishment, and system of discipline and tactics from the beginning of the monarchy to the reign of Louis XIV.; 3, 'Le Voyage au monde de Descartes,' a kind of satire of the system of that philosopher, and several other minor works; among which the 'Entretiens de Cleandre et d'Eudoxe,' are intended as a refutation of the 'Provinciales' of Pascal. Père Daniel died 1728.

DA'NTE or DURA'NTE, ALIGHIE'RI, was born at Florence A.D. 1265. By a familiar contraction of his Christian name, Durante, he was called Dante, by which name he has become generally known. His family was noble; he was a great grandson of Cacciaguida Elisei, who married a lady of the family of Alighieri of Ferrara, and whose children assumed the arms and the name of their mother. Cacciaguida accompanied the emperor Conrad III. in his crusade, was made a knight, and died in battle in Syria A.D. 1147; (*Paradiso*, cantos 15, 16 and 17,) in which Cacciaguida is made to relate to Dante his adventures, with an interesting account of the state of Florence and the primitive manners of its citizens in his time, before the breaking out of the great feud between the Guelphs and the Guibelines. Dante's father, Aldighiero Alighieri, died while Dante was yet a child. As Dante grew up he showed great capabilities for learning, in which he was assisted by Brunetto La-

mini, a celebrated scholar of the time. He became also intimate with Guido Cavalcanti, a young man of an inquisitive and philosophical turn of mind. It is asserted by some that Dante studied at Bologna, though this is not clearly ascertained; it is, however, evident from his works that he had deeply read and was imbued with all the learning of that age. By his own account he seems to have led rather a licentious life until he fell in love with Beatrice Portinari, of an illustrious family of Florence. His attachment however appears to have been purely platonic, but it served to purify his sentiments; the lady herself died about 1290 when Dante was about 25 years of age, but he continued to cherish her memory, if we are to judge from his poems, to the latest period of his life. It must have been about or a little before the time of Beatrice's death that he wrote his 'Vita Nuova,' which is a series of canzoni intermixed with prose, in which he speaks of his love in a spiritual and platonic strain, and of the change it produced in him, which was the beginning of his 'new life.'

The party of the Guelphs was at that time predominant at Florence, having some years before driven away the Guibelines with the assistance of the pope and of Charles of Anjou, king of Naples. But in the neighbouring city of Arezzo the contrary had occurred; the Guibelines, with the bishop at their head, being the stronger party, had turned the Guelphs out of the town. It may be observed that the names of these two rival factions, which in their origin designated the respective partisans of the emperors and popes, lost much of their primitive meaning as the quarrel between the church and the empire subsided by the extinction of the house of Suabia. The rivalry however between the leading families of each party continued, mutual offences were remembered, and the remembrance was bequeathed from father to son; so that Guelphs and Guibelines were ever ready to fight in every part of Italy, not for the supremacy of church or empire, but for their own municipal superiority in their respective communities; and such was the ambition of domineering that prevailed among the wealthier families, that after the Guelphs had driven the Guibelines out of town, or *vice versa*, the leaders of the party that remained in possession of the place began to quarrel among themselves, and it not unfrequently happened that some of them courted the assistance of the emigrant rival faction against their own colleagues. This occurred among other instances at Florence in 1280, when Bonaccorso degli Adimari, one of the Guelph leaders, connected himself by marriage with the Guibeline count, Guido Novello, which led to a temporary truce between the two parties. But the Guelphs soon after began to persecute the Guibelines again. The usual fate of the losing party in such cases was exile, with confiscation of property, and in case of armed opposition to or contravention of this sentence, torture and death were freely awarded, and the houses of the obnoxious individuals were not unfrequently set on fire or razed to the ground. The Guelphs of Arezzo being driven out of their town applied to those of Florence for assistance. This led to a war between Florence and Arezzo, in which the Guibelines of the latter place were defeated at Campoldino in June, 1289, when their bishop was killed. [AREZZO.] Dante was present at this engagement, and soon after his return to Florence he married Gemma Donati, of a powerful Guelph family. He now became a candidate for civic honours and offices. The citizens of Florence were classed into three ranks:—1st, grandi, or old families, formerly feudal nobles, many of whom had still feudal estates in various parts of the country, though in the town they enjoyed by law no exclusive privilege; 2nd, popolani grassi, or substantial citizens, men who had risen by trade, and many of whom were wealthier than the nobles; 3rd, piccioli, or inferior tradespeople, artisans, &c. The two last classes, weary of disturbances created by faction, and being directed by some well-meaning men, among whom was Dino Compagni the chronicler, who is the safest guide through this part of Florentine history, had made a law in 1282 by which the citizens being classed according to their trades, the higher trades, 'arti maggiori,' chose six priori, or aldermen, one for each district of the city, who were called also 'i signori' and constituted the executive. They were renewed every two months. No one could aspire to office who had not his name inscribed on the register of one of the trades. Dante enrolled his name on the register of physicians and apothecaries, though he never exercised that profession.

The institution of the priori did not prevent the town being distracted by factions as before, as those magistrates often availed themselves of their brief term of office to favour their friends and court favour with the wealthier citizens. To remedy this, the popular party, led by Giano della Bella in 1293, elected a new officer, called Gonfaloniere di Giustizia, who was to enforce order and justice, and gave him a guard of 1000 soldiers; they also excluded for ever thirty-three families of the grandi, or nobles, from political office. But a conspiracy of the wealthy families drove away Giano della Bella and his adherents in 1294, and the town again fell a prey to factions. Two powerful families, the Donati and the Cerchi, were at the head of the contending parties, and affrays between their respective partisans occurred repeatedly in the streets of Florence. Both were Guelphs, but the Cerchi were suspected of a bias in favour of the Guibelines, because they were less rigorous in enforcing the penal laws against the latter; and they had also for them the friends of the unjustly expelled Giano della Bella. The pope, Boniface VIII., favoured the Donati as being zealous Guelphs. About this time the town of Pistoia was likewise divided between two factions, called Bianchi and Neri, which originated with two branches of the family of Cancellieri. The Florentines being applied to as arbitrators, several of the more violent partisans were exiled from Pistoia, and came to Florence, where the Bianchi became connected with the Cerchi, and the Neri with the Donati, and from these connexions the two Florentine parties assumed the respective names of Bianchi and Neri. Both, as we have said above, were branches of the great Guelph party then predominant at Florence; but afterwards the Bianchi in their reverses joined the Guibelines, with whom they have been often confounded by subsequent writers. It is necessary to bear these things in mind, in order to understand the history and the political sentiments of Dante. Dante was a Guelph, and connected by marriage with the Donati, the leaders of the Neri. But he was also connected by personal friendship, and perhaps also by a feeling of equity, with the Bianchi, who appear to have shown themselves from the first less overbearing and violent than their antagonists, and to have been in fact the injured party. Dante being made one of the priori in June of the year 1300, proposed and carried a law by which the chiefs of both parties were exiled for a time out of the territory of the republic. The Bianchi were sent to Sarzana, and the Neri to Castel della Pieve. Some of the Bianchi however soon after returned to Florence, and Dante was accused of having connived at it, chiefly out of friendship for Guido Cavalcanti, who had suffered from the unwholesome climate of Sarzana, and died soon after his return. The Neri, by their agents at Rome, represented to Boniface VIII. that the Bianchi kept up a communication with the Guibelines of Arezzo, Pisa, and other places, and that if they obtained the preponderance in Florence, they would make common cause with the Colonna, the pope's personal enemies. [BONIFACE VIII.] Through these suggestions, aided by bribes distributed by the Neri at the Roman court, as Dino says, Boniface was induced to give his support to the Neri, and he sent them Charles de Valois, brother of Philippe le Bel, under the plausible title of peace-maker. Charles entered Florence in November, 1301, followed by 1200 armed men. Affecting impartiality at first, he let all the Neri return to Florence, followed by the armed peasantry; new priori were made, all favourable to the Neri, and the Bianchi began to be openly attacked in the streets. The Medici, who were already an influential family among the people, killed one of the Bianchi, and no notice was taken of the murder. A general proscription of the Bianchi now began, connived at by the peace-maker, Charles de Valois. 'People were murdered in the streets; others were dragged into the houses of their enemies, where they were put to the torture in order to extort money from them, their houses were plundered and burnt, their daughters were carried away by force; and when some large house was seen in flames, Charles used to ask, "What fire is that?" and those around him answered him that it was some wretched hovel, whilst in reality it was a rich palace.' (Dino, *Cronica*, lib. ii.) The house of Dante was one of those that were plundered. Dante was at the time at Rome, whither he had been sent by the Bianchi to counteract, if possible, the suggestions of their antagonists. On hearing the news of the proscription he hastily left Rome, and joined

his fugitive friends at Arezzo. In January, 1302, a sentence was passed condemning him to two years' exile and a fine of 8000 florins, and in case of non-payment his property to be sequestered. By a second sentence, dated March of the same year, he and others were condemned, as *barattieri*, or guilty of malversation, peculation, and usury, to be burnt alive. The sentence was grounded merely on the public report of his guilt, '*fama publica*,' which in this case meant the report of his enemies. This curious document was found in the archives of Florence in the last century, and has been transcribed by Tiraboschi, *Storia della Letteratura*, tom. v., part 2, cap. 2. Dante now began his wanderings, renouncing his Guelph connexions, and intent upon exciting the Guibelines of Italy against his enemies and the oppressors of his country. He appears to have repaired first to Verona, which was then ruled by the family of La Scala, powerful leaders among the Guibelines. But he soon after returned to Tuscany, where the Bianchi and Guibelines now united were gathering their strength in the neighbourhood of Arezzo.

The death of Boniface VIII. in September, 1303, inspired them with fresh hopes. Benedict XI., the new pope, a man of a mild and conciliatory spirit, sent Cardinal de Prato to endeavour to restore peace in Tuscany, but the cardinal was opposed by the ruling faction at Florence, who frightened him out of the town. Florence was left a prey to anarchy, during which a fire broke out which destroyed 1900 houses in June, 1304. The Bianchi and Guibelines thought of availing themselves of the confusion to surprise the town; and some of them actually entered one of the gates, but they were badly supported by those outside, and the attempt totally failed. Dante (*Purgatorio*, xvii.) censures the want of prudence and concord in the leaders on that occasion. He seems soon after to have left them in disgust, determined to regulate himself in future according to his own judgment. He says himself that 'it was difficult to say which of the two contending parties was most in the wrong.' (*Paradiso* vi., 102.) Dante appears to have been at Padua about 1306, and in the following year with the Malaspina, the lords of Lunigiana; he was also at times in the valleys of Casentino, and in the mountains near Arezzo; some say he went afterwards to Paris, and remained there some years; others believe that he did not go to France until after the death of Henry VII. in 1313. But his visit to Paris is very doubtful; though in canto x. of the '*Paradiso*,' he speaks of a certain Sigieri, professor of that university, and designates the street in which he lived.

Dante made also an attempt to obtain the revocation of his own sentence by writing to his countrymen a pathetic letter beginning with the words—'*Popule mee, quid feci tibi?*' but all to no purpose. The family of Adimari, who had taken possession of his property, opposed his return. Accordingly in canto xvi. of the '*Paradiso*,' he has launched a violent invective against them.

The election of Henry of Luxemburg, or Henry VII., to the crown of Germany, revived the hopes of Dante, as Henry was preparing to come to Italy in order to assert the long-neglected rights of his predecessors as kings of the Romans. The Guibeline leaders were ready to support his claims as imperial vicars, and the Guibeline cities, such as Pisa, were likewise in his favour. In order to strengthen their zeal, Dante, about 1310, addressed a circular letter 'to the kings, dukes, marquises, counts, the senators of Rome, and all the people of Italy, congratulating them on the prospect of happiness for Italy through the ministry of the pious Henry, who will punish the felons who opposed him and bestow mercy on the repentant,' &c. It was about this time that he wrote his book '*de Monarchia*,' which may be considered as a profession of Guibeline political faith: it asserts the rights of the emperors, as successors of the Cæsars, to the supreme temporal power, entirely independent of the popes, who are the spiritual heads of the church. This creed was in opposition to the assumed rights of Gregory VII., Innocent III., and other pontiffs, who pretended to be above all crowned heads, and to have the disposal of thrones and principalities, an assumption which the Guelphs favoured in Italy in order to keep themselves free of the imperial authority. Both parties in fact acknowledged an external superior, although both wished to rule in their respective communities with as little subserviency as possible to the nominal supremacy of either pope or emperor. But there was this difference, that the imperial, or Guibeline party, was mostly supported by the nobles, especially of

North Italy, who styled themselves vicars of the emperor, and was therefore more aristocratic in its spirit, while the Guelphs of Tuscany looked upon the pope chiefly as an auxiliary in time of need, whose temporal interference was less direct, and could be more easily evaded than that of the emperor, so as to admit of a more popular or democratic spirit in their institutions. Such at least was the theory of the two parties, for in reality the Guelph or popular families formed an aristocracy of wealth as much as the Guibelines were an aristocracy of birth and rank. Dante, in his book, '*de Monarchia*,' is no servile advocate for despotism, for he maintains that sovereigns are made to promote the good of their subjects, and not subjects to serve the ambitious pleasure of their sovereigns. The latter are to rule so as to soothe the wayward passions of men, in order that all may live in peace and brotherly feeling. But still he derives their authority from God, and he quotes in support of his system, Aristotle, the Scriptures, and the Roman History, agreeably to the scholastic logic of his times. This book '*de Monarchia*' was burnt at Bologna by order of the papal legate after Dante's death.

Henry VII. came to Italy in 1310, was crowned at Milan as king of Lombardy, and the following year he besieged Cremona, Brescia, and other places. It was about this time that Dante, impatient to see the emperor come into Tuscany to put down the Guelphs, addressed to him an epistle which begins thus:—'*Sanctissimo triumphatori et domino singulari, domino Henrico, divina Providentia Romanorum regi, semper Augusto, devotissimi sui Dantes Aligherius Florentinus et exul immeritus, ac universaliter omnes Tusci qui pacem desiderant terræ, osculantur pedes.*' He then entreats the emperor not to tarry any longer on the banks of the Po, but to advance south of the Apennines and put down the spirit of Guelph sedition at Florence, against which he inveighs in no moderate terms, and which, he says, strives to predispose against him the mind of the sovereign pontiff. He speaks of Florence as revolting unnaturally against her parent Rome, for Dante always affects to consider Rome as still the seat of the empire, and Rome and the empire are often employed by him as synonyms. This remarkable epistle, of which we had only an Italian version until the Latin text was discovered not many years since in the library of St. Mark, is dated from Tuscia, near the founts of Arno, April, 1311. (*Dantis Alighierii Epistolæ quæ extant, cum notis Caroli Witte, Padua, 1827.*) Henry came into Tuscany, threatened Florence, but without effect, was crowned at Rome, and on his return died suddenly at Buonconvento, near Siena, in August, 1313. This was a terrible blow to the hopes of the Guibelines, and of Dante especially. He now took refuge at Verona, at the court of Cane della Scala, where he appears to have been before, between 1308 and 1310. Cane was hospitable and generous to the Guibeline emigrants, but Dante, with his proud spirit and temper soured by adversity, could ill accommodate himself to the flattery of courts and the flippancy of courtiers, and he is said to have had some unpleasant bickerings with the people about Cane.

In a well-known passage of his poem he feelingly deploras the lot of the exile who is constrained to eat the bitter bread of patronage:—

'Tu proverai sì come sà di sale,
Lo pane altrui, e com'è duro calle,
Lo scendere, e 'l salir per l'altrui scale.'
PARADISO, Canto xvii.

With Cane himself, however, he seems to have continued on good terms; he speaks very highly of his hospitality in a passage just preceding the above lines, and there is a cordial letter from him to Cane, written probably in the latter years of his life, in which he dedicates to him his '*Paradiso*,' the latter part of his great poem, and explains the object of it. He says that he styled it a comedy, because, contrary to the style of tragedy, it begins with sorrow and ends with joy; he distinguishes between the literal and the allegorical sense of his verses, and observes that his poem may be called polysensuum, having many meanings. He tells Cane the title of his work:—'*Incipit Comœdia Dantis Alighierii, Florentini natione non moribus.*' But the title of the part which he sends to him with the letter is:—'*Incipit Cantica tertia Comœdiæ Dantis quæ dicitur Paradisus.*' It is evident from this and other circumstances, that Cane had not seen the rest of the poem; indeed it is not likely that Dante ever communicated the whole of it to any one during his

lifetime, as it would have made it impossible for him to have found refuge anywhere, as Foscolo closely argues in his very elaborate and very critical 'Discorso sul testo di Dante,' which is one of the most judicious and scholar-like commentaries on that poem.

Of Dante's *Commedia* we cannot enter here into any details, and we must refer the reader to the numerous commentaries, illustrations, and translations of it in every language of Europe. It is one of the few works of imagination which have stood the test of ages, and which will pass down to the remotest generations. It resembles no other poem; it is not an epic; it consists of descriptions, dialogues, and didactic precepts. It is a vision of the realms of eternal punishment, of expiation, and of bliss, in the invisible world beyond death. Its beauties are scattered about with a lavish hand, in the form of episodes, similitudes, vivid descriptions, and above all, sketches of the deep workings of the human heart. It is especially in this last department of poetical painting that Dante excels. Whether he describes the harrowed feelings of the wretched father in Ugolino, or the self-devotedness of the lover in Francesca, or the melting influence of the sound of the evening bell on the mariner and the pilgrim; whether he paints the despair of the reprobate souls gathered together on the banks of Acheron, cursing God and the authors of their being, or the milder sorrow of the repentant, chanting the 'miserere' along their wearisome way through the regions of purgatory,—he displays his mastery over the human feelings, and his knowledge of those chords that vibrate deepest in the heart of man. No other writer except Shakspeare can be compared to Dante in this respect. His touches are few, but they all tell. His power of invective is grand and terrific; witness his imprecations against Pisa, against Florence, against his enemies, his address to the German, Albert, representing to him the anarchy of Italy, and his repeated denunciations of the vices of the court of Rome. Yet Dante was a sincere Catholic; in his poem he places the heretics in hell, and Dominic in paradise; and manifestly shows everywhere his belief in the dogmas of the Roman church, but he attacks its discipline, or rather the relaxation of its discipline. He urges, like Petrarch and other Catholic writers of that and the following ages, the necessity of a reform; and above all, of a total separation of the spiritual from the temporal authority, things generally confounded by the Roman canonists. That many parts of his poem are allegorical is evident, but that the whole poem is an allegory, a political mystification, as some have pretended, seems a far-fetched hypothesis, an ingenious paradox. Dante was a declared enemy to the Guelphs of Florence and their allies, the Papal court and the king of France; and he poetically represents these three at the beginning of his poem by the emblems of the panther, the wolf, and the lion; but soon after he drops all metaphor, and inveighs against all three in the plainest and the bitterest terms, which he would not have done had he meant to be understood only by the adepts of a secret sect. In canto xix. of the *Paradiso* he passes in review all the kings of his time, and spares none of them in his reproof; in another place he has something to say against almost every one of the Italian cities and populations. In fact Dante never published his whole poem in his lifetime, for he had spoken in it too plainly to be able to publish it in safety. He wrote it out of the fullness of his heart, in detached parts, and at different periods, and his strains were influenced by the various political vicissitudes of the times, and by his own alternate hopes and despondency. About the year 1316 he had still a chance of his recall to Florence. It was suggested to him by a friend whom Dante in his reply calls father, probably because he was a clergyman, that he might return, provided he acknowledged his guilt and asked absolution. His answer was characteristic of his mind: 'No, father, this is not the way that shall lead me back to my country. But I shall return with hasty steps if you or any other can open me a way that shall not derogate from the fame and honour of Dante; but if by no such way Florence can be entered, then to Florence I shall never return. Shall I not everywhere enjoy the sight of the sun and stars? May I not seek and contemplate truth anywhere under heaven without rendering myself inglorious, nay infamous, to the people and commonwealth of Florence? Bread, I hope, will not fail me.' (See text and translation of this letter in Foscolo's *Essays on Petrarch and Dante*, 8vo., 1823, with a sketch of Dante's character.

In 1317-18 Dante appears to have been still wandering about Italy. In 1319 he repaired to Guido da Polenta, lord of Ravenna, where he was hospitably received, and where he appears to have remained till his death, which happened in September, 1321. He was buried in the church of the Minorites, under a plain monument. Bernardo Bembo, senator of Venice and podesta of Ravenna, raised to him a mausoleum in 1483, which was afterwards repaired in 1692 by cardinal Corsi, of Florence, and lastly in 1780 reconstructed altogether in its present form by cardinal Valenti Gonzaga, legate of pope Pius VI. The reproof—

* Ungrateful Florence! Dante sleeps afar,

was at last felt by the Florentines; a subscription was made and a monument was raised to the memory of Dante in the church of Santa Croce, which was opened to public view with great solemnity on the 24th of March, 1830. (Missirini, *Delle Memorie di Dante in Firenze*, 1830.)

For the manner in which the whole MS. of Dante's poem was found, collected, transcribed, and published, after his death, by his sons Jacopo and Piero, the early commentaries on the poem, its early printed editions, and the whole bibliographic history of the work, the reader will find ample information in Foscolo's *Discorso sul testo di Dante*, London, 1825; and also in Missirini, *Rivista delle varie Lezioni della Divina Commedia, e Catalogo delle piu importanti Edizioni*, Padova, 1832. Among the most complete editions of Dante's poems are: that of Venice, 5 vols. 4to., 1757-8, with ample notes, and including Dante's Life, by Pelli, and his minor poems and prose works; Lombardi's edition, Rome, 3 vols. 4to., 1791; and that of Florence, with illustrative plates, 1819, 4 vols., fol. Among the host of commentaries the one called l'Anonimo, and also l'Ottimo, written by a contemporary of Dante, who was evidently familiar with the poet, has been published for the first time at Leghorn in 3 vols., 8vo., 1827.

Among the numerous translations of the 'Divina Commedia,' in almost every language of Europe, that in English verse by Cary deserves to be mentioned with especial praise. An Italian translation of Dante's philological treatise 'De Vulgari Eloquio,' was published by Trissino in 1529; and the Latin text in 1577: this work has occasioned a very animated controversy between Italian philologists in our days.

DANTON, GEORGE JAMES, born at Arcis-sur-Aube, October 26, 1759, was one of the most remarkable characters among the leaders of the first French Revolution. He was educated for the bar, and was pursuing the peaceful avocation of a king's counsel when the first shocks of the great political earthquake called him upon the revolutionary arena. Danton was gifted by nature with those faculties which qualify a man for the dangerous office of a political agitator. He was tall and muscular, his features harsh and striking, and his voice resembled the roaring of breakers or the growling of the thunder. He was ambitious and bold; his eloquence, the offspring of an impassioned imagination, though without the charms of rhetorical elegance and philosophical depth, was overwhelming by its vehemence. It is no wonder that such a man soon became the leader of popular commotions and the terror of all who dared to oppose him.

In 1790, supported by the revolutionary club of the Cordeliers, founded by himself, he presented to Louis XVI. the petition of the forty-eight sections of the town of Paris against the king's ministers, accusing them of having lost the confidence of the nation. In 1791 he was elected member of the departmental administration of the Seine. After the imprisonment of Louis at Varennes, he was the prime mover of the popular assemblage of the Champ de Mars, in which he called for the dethronement of the king. On the 8th of August, 1791, he presented himself before the legislative assembly, and with unprecedented audacity told the representatives of France that their refusal to declare the throne vacant would be the signal for a general insurrection. The fate of Louis was decided, and Danton being elected minister of justice, became the head of that body of six men who were intrusted with absolute executive power. In this capacity he showed himself blood-thirsty, ambitious, vindictive, and mercenary; but he was also courageous and skilful in conducting public affairs at a time when every step was attended with danger.

When the Prussian army had entered France, and consternation began to spread in all quarters, when the leaders

of the republican party were at a loss what to do to avert the impending hurricane, Danton ascended the tribune, and addressed the convention in one of the most impassioned speeches ever uttered by a demagogue; he ended with these eventful words:—'The country is in danger; to avert the crisis one thing only is needful—boldness, incessant boldness, nothing but boldness.' These words acted like a spell upon the French nation; within a few weeks fourteen republican armies stood upon the field of battle, and repelled with unexampled bravery the aggression of the allied forces.

If Danton had turned his energies only against the enemies of his country, his memory might have passed unsullied to posterity: but he allowed his wild passions to rage against his fellow-citizens; and most of the horrors of the French Revolution, particularly those of the days of September, were originated, supported, or encouraged by him. After the abolition of royalty Danton gave up the office of minister of justice for that of a president in the constituent committee and in that of Public Safety. While discharging these functions he prepared public opinion for the decapitation of the king. When the tribunal whose business it was to pass the sentence of death was sitting, Danton was absent; but he returned in time to vote for the king's execution. Like Sieyes, he gave no reason for his vote.

In the meantime the people of Paris, or rather the party which was headed by the clubs of the Jacobins, had chosen another leader, who in his private conduct was the opposite of Danton, and in his political views his most powerful antagonist. This was Robespierre, a man of singular character, who combined with the greatest moral purity and disinterestedness a stern, profound, uncompromising political character. Danton acted the republican in order to elevate himself; civil bloodshed was for him only the gratification of private revenge; the proscription of others a rich harvest for his own cupidity. Robespierre sought nothing for himself; the social regeneration of his own country and of the whole of mankind was his only aim. In the presence of Robespierre, Danton felt himself shorn of his laurels; he trembled at the thought of losing his ill-gotten wealth, and having failed in overpowering his antagonist, he withdrew from the theatre of political action, stigmatizing his rival by the name of 'ultra-revolutionist.' When summoned to give an account of his financial administration, he refused to submit to such examination, unless his five colleagues were also compelled to do the same, and retired to his native place.

It appears that, under the influence of hatred of Robespierre, and prompted probably by his avarice or ambition, he entered into some treasonable plot with the Duke of Orleans ('Egalité') and some other enemies of the republic. St. Just denounced him as a traitor before the Comité de Salut Public, and Danton was arrested the 31st March, 1794, and beheaded the 5th April of the same year.

Danton belonged to the school of the French materialists, and did not believe in the immortality of the soul. During the trial, and even on the scaffold, he preserved his undaunted courage. 'Soon,' said he to the executioner, 'I shall fall back into my original nothingness; yet my name shall live for ever in the pantheon of history.' He left a wife, but no legitimate children.

DANUBE, The, called by the Germans Donau, and by the Hungarians Duna, is a river of the first rank, and the second of European rivers, being inferior only to the Volga. Its course is calculated to be about 1770 miles, and the surface drained by it and its numerous tributaries probably exceeds 300,000 square miles.

In its long course from west to east it traverses more than 22° of longitude (from 8° 10' to 30° 30' E. long.); the most northern part of its basin falls only a little north of 50° N. lat., and the most southern does not reach 42° N. lat. But though the countries drained by it do not extend over eight degrees of latitude, they differ greatly in climate and productions, a circumstance owing to the different elevation of the three great plains which are traversed by this river. The most western, the plain of Bavaria, is between 1100 and 1200 feet above the level of the sea; the central plain, or that of Hungary, about 300 feet, and the lower plain, or that of Wallachia, probably less than 100 feet. Geographers have divided the course of the river into three parts. Its upper course is through the hilly country which surrounds its sources, and through the Bavarian plain

and the mountains which divide that plain from the plains of Hungary. It terminates a few miles east of Vienna. The middle course extends from Vienna to the Demirkapi, which divides the Hungarian from the Wallachian plain, and the lower course traverses the last-mentioned plain.

The Danube originates on the eastern declivity of the Black Forest, about twenty-four miles from the banks of the Rhine, in 48° 6' N. lat., and 8° 9' E. long., at an elevation of about 3000 feet above the sea. It is here a mountain torrent, which is called Breghe. Near Danauesingen it is joined by another mountain-stream, after which junction it receives the name of Donau, or Danube. Its general course at first is to the east, but afterwards it declines to the north-east, in which direction it continues till it reaches Ratisbon. From this place to Efferding, some miles west of Linz, it runs south-east by east, and from Efferding its general course is east. At Ulm, where it is joined by the Iller from the south, the river becomes navigable for barges; its surface is here 1255 feet above the level of the sea, and at Donauwörth, where it enters the plain of Bavaria, 1160 feet. Before it enters that plain it runs for the most part of its course along the southern base of the dry and sterile table-land called the Rauhe Alp, which rises to an elevation of 2000 feet and upwards above its level, and contributes to it only a few rivulets. On the south numerous offsets from the Alps approach the river, forming hills of moderate elevation with gentle declivities, and inclosing charming valleys of great fertility. The affluents which descend from these valleys to the Danube are numerous. The Iller rises in the Alps, on the western declivity of the Hoch Vogel, and runs nearly due north to Ulm; the Lech originates in the Alps of the Vorarlberg, and runs near its source east, but afterwards north; it enters the Danube a few miles below Donauwörth, and bounds the Bavarian plain on the west.

The Danube runs through the Bavarian plain from Donauwörth to Passau, changing nearly in the middle of its course from north-east to south-east. At Ingolstadt it is 1140 feet, at Ratisbon 1050 feet, and at Passau 800 feet above the level of the sea. That portion which lies south of the river is an extensive plain, which reaches to the very foot of the Alps, and on which comparatively few hills and rocks are dispersed. It is traversed in a diagonal line by the Isar, which rises in the northern districts of Tirol, and runs north-east; this river is not navigable by barges, but timber and fire-wood are floated down. On the eastern boundary of the plain runs the Inn, which has been noticed under AUSTRIA (vol. iii., p. 136). The plain north of the Danube has a much more uneven surface, rising frequently into gentle hills, which however nowhere attain the height of mountains. This plain extends beyond the boundary of the basin of the Danube, to the very banks of the Main, and even to the north of this river. As the high ground which separates the two river basins in this plain is not much elevated above the level of the Danube in this part, a water communication by a canal between the Danube and the Rhine could easily be effected. Charlemagne begun such a work, and near the town of Weissenburg a few traces of it are still visible. The Bavarian government took up the matter in 1834. This new canal is to begin on the Danube, near Kelheim, at the mouth of the Altmühl, to follow the bed of the last-mentioned river and of the Sulz to Neumarkt, and to pass thence over the water-shed to Nürnberg into the valley of the Regnitz; then to run in the bed of this river to Bamberg and the Main. [BAVARIA, note.] Besides the Altmühl, this plain is traversed by two other considerable affluents of the Danube, the Naab, which rises in the Fichtelgebürge and flows southward, and the Regen, which originates on the south-western declivity of the Böhmer Wald, and has a general western course.

The third part of the upper course of the Danube is that between Passau and Vienna. At Linz its surface is 650 feet, at Vienna 421 feet, and at its entrance into Hungary 417 feet above the level of the Black Sea. Through all this distance it runs between the steep offsets of the Böhmer Wald, and the northern ranges of the Alps of Salzburg and Styria, which here in some places attain a great elevation (from 3000 to 5000 feet). The level country on the banks of the river is of small extent, except as we approach Vienna, where the mountains recede so far as to leave a considerable plain on both banks. In this part of its course the Danube receives the Traun, the Ens, and the

Marosh [AUSTRIA], and divides in several places so as to form islands, especially above and below Linz, and in the neighbourhood of Vienna. But the current of the river here, as well as in the Bavarian plain, is so rapid, that, properly speaking, it can only be navigated downwards: the barges must be tracked up the river. It has no rapids, but several dangerous whirlpools.

In its middle course the Danube first traverses the Lesser Hungarian plain. At Presburg it is 401 feet, at Winshegrad 379 feet, above the sea, and at Ofen or Buda, which lies in the Great Hungarian plain, 348 feet above the sea. In its course through the lesser plain the current of the river is still rapid, though much diminished. It divides into numerous branches, which inclose islands, among which the largest is the island of Schütt, which is upwards of fifty miles long, and from four to nine miles across. As the adjacent country consists of very soft alluvial soil, the river frequently changes its course. Some ten years ago a minute survey was made of the river for the purpose of some important improvements. Several years were spent in considering these projected improvements, and when their execution was to begin, it was found that the maps which had been made were of no use, the river having changed its bed in nearly every part. In this plain the Danube is increased by the waters of the Leitha and Raab from the south, and the Waag and Gran from the north.

Between Gran and Waitzen the river flows between two mountain ridges. That on the south is the northern extremity of Mount Bakony, and on the north an offset of the Carpathians, called the Neograd range. At Waitzen it issues from the mountain defile, and changes its eastern into a southern course. In this direction it flows with a slow current and numerous windings through the greater plain of Hungary for nearly three degrees of latitude, till it meets, after its junction with the Drave, the Sirmian range or Mount Werdnik, which again deflects it towards the east. It then skirts the Hungarian plain on the south, dividing it from the hilly Slavonia and the mountainous Servia, till it arrives near Nova Moldava, where it again passes through a mountain valley. During its course through the Hungarian plain its waters are increased by those of the Sarvitz, Drave, and Save from the west, and Theiss and Temesh from the north. [AUSTRIA.] At Buda its surface is 348 feet, at Zambor 272 feet, and at Nova Moldava probably not much more than 200 feet, above the level of the Black Sea. Its average breadth between Waitzen and the mouth of the Drave is 600 yards, and its depth varies from 5 to 20 feet.

The mountain-valley of the Demir Kapi (the Iron Gate) is formed on the north by the Banat range, an offset of the Transylvanian Carpathians, and on the south by a lateral range of Mount Balkan; it extends from Nova Moldava in the Banat to Cherniz in Wallachia. In entering this narrow valley the rapidity of the river gradually increases. About four miles below the village of Dobra it forms a dangerous whirlpool, called Takhtali; and about the same distance below New Orsova is the Demir Kapi, where a ledge of rocks runs across the bed of the river, over which the water rushes with great noise, producing below it a number of dangerous whirlpools. Vessels drawing not more than 2½ feet may however descend it, when the water is not low; but it is impossible to ascend it, and thus this rapid, which does not occupy a space above 2000 yards in length, interrupts all water communication between Hungary and Turkey. It is supposed however that this obstacle could be removed at no great expense. At the Demir Kapi the Danube leaves the Austrian dominions and enters Turkey. A few miles lower down it issues from the valley, the country to the north sinks down to a flat, and the current of the river becomes slow and gentle.

On the mountains and hills which inclose the valley of the Demir Kapi on both sides are very numerous remains of Roman antiquities, which were investigated by Count Marsigli in the beginning of the last century, when this region was ceded to Austria by the peace of Passerowitz: an account of these remains is given in Marsigli's *Danubius Panono-Moesicus*, with a great number of inscriptions. Some few remains occur farther down the river, which are noticed by Marsigli. He also describes the remains of the bridge built by Trajan over the Danube, a short distance below the rapids of the Demir Kapi.

Along the lower course of the Danube the country on the south continues mountainous from the Demir Kapi to

Lom Palanka; it afterwards becomes hilly, and by degrees sinks into a flat plain: east of Silistria it presents nearly a level surface with some swamps. The country to the north is the great level of the Wallachian plain. In this tract the river first runs nearly south from Chernitz to below Widden, then turns to the east and continues in that direction to about forty miles from the Black Sea, where it suddenly bends to the north. In this direction it runs upwards of 100 miles to the junction with the Sereth, and hence again to the east to its mouth. In this course the river frequently divides and forms numerous large islands, especially below Silistria. Its width, where it is not divided by islands, is between 1500 and 2000 yards, and its average depth being above 20 feet, it is navigable by vessels of considerable burden. From the north it receives the Aluta, or Alt, Sereth, and Pruth, which rise in the eastern Carpathians [AUSTRIA], and from the south the Morava, which is formed by two large rivers, the Western and Eastern Morava, which drain a great portion of the northern declivity of Mount Balkan and the Isker. [BALKAN.]

After having been joined by the Pruth, the Danube divides into several branches, which do not unite again, and thus it flows into the Black Sea by seven mouths, which are (enumerating them from north to south) Kilia Bagasi, Suline Bagasi, Kedrille Bagasi, Salvoa Bagasi, Kutsuk Bagasi, Portesca Bagasi, and Kurte Bagasi. The three last issue from the lake of Ramsin. Suline Bagasi is considered as the principal mouth, and is most navigated. It forms the boundary between Russia and Turkey.

The following particulars on the subject of the steam navigation on the Danube are from the Report of the Vienna Society to the 31st December, 1836. The company will soon have ten steam-vessels afloat besides a towing steamer. The present voyages performed are from Vienna to Lintz; from Vienna to Pesth; from Pesth to Drenkova; from Skela-Kladova to Galaez; from Pesth to Semlin; from Galaez to Constantinople; from Constantinople to Trebisond, and from Constantinople to Smyrna. The vessels engaged on these lines are eleven in number.

The Danube was known to the early Greek writers under the name of Istros (*Ἰστρος*), called by the Romans Ister, which was probably the genuine name of this river in the lower part of its course. The Romans learned the name Danubius from the natives on the upper course of the stream, with whom they were brought into contact by commerce and by conquest. Herodotus in his 4th book (chap. 48, &c.), has transmitted to us all that was known in his time of the Danube and its tributaries in the middle and lower part of its course. Strabo observes (p. 304), 'the upper parts of the river and the parts at its source, as far as the cataracts, are called Danubius, and flow chiefly through the country of the Daci; the lower parts as far as the Pontus (the Black Sea), and in the neighbourhood of the Getæ, are called Istrus.'

(Hoffmann's *Deutschland and seine Bewohner*; Berg-haus, *Annalen*, Nos. 127 and 134.)

DANZIG, one of the four administrative circles of the province of Prussia, consisting of portions of what was formerly called Western Prussia. It lies between 53° and 55° N. lat. and 7° and 10° E. long. Its northern boundary for about 92 miles is the Baltic; on the east it is bounded by the circle of Königsberg, and on the west by Pomerania. Its area is about 3197 square miles. The surface is level, with a gradual slope from the banks of the Vistula to the Baltic, and is occasionally broken by small elevations, which the natives designate by the name of Berge (or mountains), and of which the highest is but 500 feet. The soil is in many parts sandy, and there are several tracts of swamps; but in general it is productive, and along the banks of the Vistula exuberantly fertile. The circle raises more grain than its consumption requires, and great quantities of vegetables and fruit. The minor circle of Marienburg has extensive woods and forests, of which Danzig contains altogether nearly 800,000 acres. Horses and cattle, though in general of an inferior kind, abound on the luxuriant pasture grounds of the low lands. There are very considerable fisheries along the coast, and salmon, eels, and other fresh-water fish are taken in great quantities in the inland lakes, sheets of water, and streams, such as the Frische Haff, Strand See, Drausensee, &c. Amber is obtained on the shore in the vicinity of Danzig. The principal rivers which water this circle are the Vistula, Schwente, Sorge, which takes the name of the Elbing

before it falls into the Frische Haff, Thiene, and Motlau. Danzig contains 12 towns, 6 market-towns, and 2047 villages, and is divided into 7 minor circles; viz.

	Sq. miles.	Pop. 1831.	Chief Towns.
Danzig	491	112,827	Danzig, 54,800
Neustädt	553	35,264	Neustädt, 1450. Putzig, 1950
Karthus	549	29,157	Karthus, 350
Elbing	272	46,683	Elbing, 22,400. Toklemist 1700
Marienburg	317	44,807	Marienburg, 5600. Neuteich, 1640
Stargard	533	34,681	Stargard, 3000. Dirschau, 2200
Behrendt	482	23,130	Behrendt, 1600. Schöneck 1700
	3197	326,549	

In 1817 the number of inhabitants was 242,547, so that the population between that year and 1831 had received an accession of 84,002 souls. At present (1837), it is estimated at about 340,000. In 1835, the number of births was 13,444; and of deaths, 10,306; which gives an increase for that year of 3138. The manufactures of this circle, of which the leading branches are woollens, linens, leather, and beer, are not extensive, and are situated almost wholly in the larger towns. A very extensive trade is carried on with foreign parts from the ports of Danzig and Elbing.

DANZIG, or GDANSK, in $54^{\circ} 21' N.$ lat. and $18^{\circ} 38' E.$ long., the capital of the administrative circle, is on the left bank of the principal arm of the Vistula, about three and a half miles from the shores of the Baltic. It is traversed by the Motlau and Radaune, which flow by several channels into that river. In ancient records it is called Gidanie and Gedansk. The first mention of it occurs in the tenth century, and it was long afterwards a bone of contention between the Danes, Swedes, Pomeranian princes, and Teutonic knights. In 1454 it sought the protection of the kings of Poland, who recognized its independence to the fullest extent, and admitted its citizens to enjoy every right possessed by the Poles themselves. In 1733 it gave shelter to King Stanislaus, but, after enduring a furious bombardment by the Russians and Saxons, was forced to acknowledge Augustus II., his rival, as legitimate sovereign of Poland. Prussia, by her acquisitions, at last hemmed in this little state so completely, that in 1772 its commerce with the interior was almost annihilated by heavy dues laid on its exports by that power. On the re-partition of Poland in 1793, Danzig was compelled to admit a Prussian garrison, and to make its usages harmonize with the institutions of its new masters. From this time until the breaking out of the war between France and Prussia in 1806, the town again rose to affluence and prosperity, but it experienced another reverse in 1807, on its falling into the hands of the French, by whom it was besieged for four weeks, under the command of Lefevre, subsequently Duke of Danzig. In the same year the treaty of Tilsit erected the town and a surrounding tract of about 230 square miles into a free state under the antient Danzig code of laws. The French, in spite of this change, treated the town as their own possession, burthened it with enormous contributions, and governed it by the 'Code Napoleon.' Again its trade was almost annihilated; and this unfortunate state of things continued until the 24th December, 1813, when it capitulated to the Russians and Prussians, after sustaining a severe and destructive siege of eight months. On the 3rd of February following, the King of Prussia was again recognized as its full sovereign. Danzig is at this time one of the strongest fortresses and most flourishing towns in his dominions. Many parts of it are in the fine old style of building, though not regularly laid out; but a great number of the streets are narrow and crooked. Within the walls, which consist of ramparts, wet-ditches, crossed by four drawbridges, leading to as many gates, nineteen bastions and the citadel of Hagelsberg, forts Zigankaberg and Bischoffsberg on adjacent eminences, the town is divided into the Altstadt, Vorstadt, Rechtsadt, Niederstadt, Langgarten, and Speicher-insel, and is about two and a quarter miles in circuit. Without the walls there are nine suburbs. The Langgarten, the finest quarter, is traversed by a broad handsome street, planted with lindentrees; the Rechtsadt too has some spacious streets and handsome houses in it; but the Old Town (Alt-stadt) is what its name almost implies, close, dirty, and ill-constructed. There are no spacious or even regular squares; the markets themselves being no more than broader kinds of streets. The Speicher-insel contains the storehouses

and magazines. The number of houses was in 1804 5340, with 49,465 inhabitants; in 1817, 4561, with 52,821 inhabitants; in 1825, 4690, besides 600 in the suburbs; and in 1831, 5201, with 56,932 inhabitants, besides the garrison, the number of which is about 7000. There are 21 churches in all, 13 of which are Lutheran, 4 Reformed-Lutheran, and 4 Roman Catholic. St. Mary's, the High Church, a Lutheran place of worship, is a remarkable edifice built in the shape of a cross; it was commenced in 1343, and finished in 1401; the roof rests on 28 columns, and its exterior is ornamented with 10 small towers; it has a lofty steeple, 3722 windows, and 19 altars. A Dutch painting of the Last Judgment, for which the emperor Rudolph offered 40,000 dollars, is suspended against one of the columns. There are also 2 Mennonite places of worship, 2 synagogues, 3 monasteries, and a convent, in the town. Danzig is the seat of the provincial administration. Its schools consist of a royal school of navigation; a gymnasium with 7 professors, and a library of nearly 30,000 volumes, the 'Grey cloisters,' a public seminary founded in 1580, a normal school, 2 superior civic schools, a school of arts, and a peace society (Frieden's-gesellschaft), which enables 16 young men of talent to complete their studies at the universities and elsewhere. It has a board of trade and navigation, a tribunal of commerce, a humane society, a public library, an orphan asylum, and house of correction, a foundling hospital, an infirmary and obstetric institution, 4 hospitals, and societies of natural history and of natural and experimental philosophy, to the latter of which an observatory is attached. There are yards and slips for shipbuilding; sugar refineries, spirit and liqueur distilleries, breweries, copperworks, and manufactories of silks, woollens, linens, leathers, hats and gloves, soap and starch, earthenware, arms, steel-ware, hats, tobacco, &c. Independently of these branches of industry, the town has a very considerable trade with the adjacent provinces and foreign parts, and exports large quantities of corn, timber, pot and pearl ashes, quills, brandy and spirits, wool, flax and hemp, &c. It has been calculated that the annual value of the exports is more than six millions of dollars, or about 830,000*l.*, and of the imports upwards of two millions, or about 275,000*l.* Above 630 vessels enter the port annually, and the tax on trading occupations produces above 4300*l.* a year. Among the outworks is the intrenched camp on the island of Neufahrwasser, which covers the approach from the Baltic.

DAPHNE, a genus of thymelaceous plants, containing many species, inhabiting the more temperate parts of Europe and Asia. Among them some are cultivated in gardens for their beauty or fragrance, others are of medicinal importance, and a few are employed in the manufacture of hemp and paper. We shall briefly notice the more remarkable of these.

The genus *Daphne* is distinguished in its natural order by having eight or ten stamens inclosed within the calyx, a simple stigma, a succulent fruit, and a calyx the orifice of whose tube is destitute of appendages.

D. Mezereum, the mezereon of the gardens, is a deciduous plant, with white or purple fragrant flowers, sitting close to the stem, and appearing on the naked branches before the leaves are unfolded. It is a favourite in gardens, and succeeds in almost any well-drained light soil where the air is not poisoned by the smoke of coal-fires. It is found wild in the mountainous woods of many parts of the middle and south of Europe. It is met with in woods in various counties of England: the berries are smooth, shining, and bright red.

All the parts of this and indeed of the other species, as far as they have been examined, are extremely acrid and poisonous. If the bark is bruised and applied to the skin it produces severe blisters, and is sometimes substituted for cantharides when that drug cannot be employed with safety. Taken internally, the bark, leaves, and fruit act as cathartics, but require to be administered with extreme caution; for they are apt to produce dangerous and even fatal consequences. Linnæus speaks of a person having been killed by a dozen mezereon berries; and they are employed in Sweden to poison wild animals. According to Fée, the very odour of daphne, agreeable as it is, is attended with danger; he says that if kept in sitting-rooms they will bring on headache and fainting. It is moreover asserted that Russian and Tartarian women sometimes rub the berries of the mezereon on their cheeks

to produce a slight irritation, which of course gives the effect of rouge, only in a more permanent degree.

D. Laureola, the spurge laurel, is another British species, found wild commonly in woods and hedges. It is a handsome evergreen bush, with the aspect of a laurel. The leaves are placed very close together; they are of a leathery consistence, deep green, lanceolate, acute, and narrowed to the base. The flowers are green, and grow in little short clusters, which are nearly concealed by the leaves. The berries are, when ripe, a deep purple black. We have no species that grows more readily beneath the shade of trees; and as its appearance is highly ornamental, it would be a most useful garden plant, if it were not for the dangerous berries, which children are apt to eat. An ointment for keeping open blisters is prepared from this plant.

D. pontica, one of the plants which is reputed to have contributed to the poisonous quality of the honey that was eaten by Xenophon's soldiers, is very like this species, and is often cultivated as a hardy evergreen.

D. Gnidium, the Garou bush, an evergreen with narrow sharp-pointed erect light-green leaves, and branching clusters of white fragrant flowers, is a common plant in dry waste places in the south of Europe. It will not live in the open air in England, except in the warmest counties. Both the berries and leaves are employed by the French as purgatives; the plant also affords a good yellow dye.

D. Cneorum, a native of grassy places in the Alps of Switzerland and the rest of central Europe, with its trailing stems, numerous small narrow blunt deep-green leaves, and clusters of rich purple fragrant flowers, is one of the most beautiful of all plants, when it finds a soil and climate that suit it. At Bagshot, for instance, and in similar situations, it is, under good management, quite unrivalled by the other hardy shrubs among which it grows. It will not succeed where the soil is otherwise than sandy and peaty, nor can it bear the impure atmosphere of large towns.

D. Collina, *Alpina*, *Neapolitana*, and *Tarton-raira* are other species cultivated in gardens. The first has dull purple sweet-scented flowers, and is sufficiently common in collections; the others are rarer. All are impatient of wet in winter; but if at that season kept tolerably dry, will bear considerable frost, and are desirable garden plants in the milder parts of England.

In addition to the acid and dangerous properties which appear to be common to them all, some species are remarkable for the toughness of their fibre, and for the economical purposes to which they are applied. From *D. Cannabina* is prepared the best kind of writing-paper in China, according to Loureiro; but it must be observed that this statement, if true, is at variance with what is observed in Nepaul, where the daphne-paper is very brittle and bad.

D. Lagetta, the lace-bark tree of Jamaica, is most remarkable for the tenacity of the fibre of which its bark consists, and for the facility with which it may first be separated into thin layers and then into distinct meshes. If the inner bark of this plant be macerated in water, it may be readily separated into layers no thicker than the finest lace, and which, after having been pulled a little sideways, resembles in some measure that fabric. King Charles II. is said to have had a cravat, frill, and ruffles of lace-bark presented to him by his governor of Jamaica.

DAPHNE MEZEREUM is an indigenous shrub; the bark obtained in spring from the stem, the thick branches, and even the root, is officinal. It is covered by a thin epidermis, green within, brown without. It is destitute of smell, but has a very acrid pungent taste, lasting for hours, and causing vesications. Its virulence even amounts to a poisonous degree, but is said to be lessened by camphor.

In the London Pharmacopœia it only enters as an ingredient into the decoction sarsap. comp. It consists of an acrid resin and daphnin.

The bark yields its properties to water, and still more perfectly to vinegar. The simple decoction of the Edinburgh Pharmacopœia certainly possesses considerable power. Mezereon in a small dose acts upon the secretions of the salivary glands, the mucous membranes, the kidneys, and the skin. It also rouses the nervous energy of the brain, as its action in many cases of coma and stupor proves.

It may be employed locally to stimulate the salivary glands, or to remove paralysis of the mouth or throat; when

so employed it is to be chewed, but the saliva must not be swallowed, as its acrimony causes inflammation of the stomach and intestines; and this may even be fatal from the hæmorrhage, vomiting, and purging which attend it. The berries swallowed incautiously produce the same bad effects.

The simple decoction, along with carbonate of ammonia, given in proper doses every two or four hours, has in several instances rescued patients from a state of imminent danger in the stage of collapse of typhus fever, or that of coma and effusion at the base of the brain, which sometimes occurs in scarlet fever. In torpor of the brain, in leuco-phlegmatic subjects, and in approaching amaurosis, it is also of use. It has also been found serviceable in chronic rheumatism and chronic cutaneous diseases. A portion of the bark macerated in vinegar and applied to the skin, forms a powerful vesicant.

DA'PHNIA. [BRANCHIOPODA, vol. v. p. 343.]

DAPHNIN. Vauquelin first pointed out, in the 'Annales de Chimie,' t. lxxiv., the existence of a peculiar acrid principle in the mezereon (*Daphne Mezereon*). Its properties have been since more particularly examined by Gmelin and Bär. It is prepared by precipitating a decoction of mezereon bark by subacetate of lead, and decomposing the washed precipitate by sulphuretted hydrogen; the solution is then filtered, evaporated, and the residue digested in cold anhydrous alcohol, from which daphnin crystallizes.

When it has been purified by washing with cold alcohol, solution in water, and recrystallization, it forms colourless bitter crystals, which are neither alkaline nor acid: in cold water they are sparingly soluble, but more so in hot, and also in alcohol and æther. Nitric acid converts it into oxalic acid. It does not appear to have been analyzed.

DA'PSUS, a genus of Coleopterous insects. [EUMORPHUS.]

DA'PTUS (Fischer), a genus of Coleopterous insects of the family Harpalidæ. Generic characters:—mentum deeply emarginated and without any tooth-like process in the middle; antennæ rather short, and moniliform; second joint of the labial palpi somewhat oval; four basal joints of the four anterior tarsi slightly dilated, short, and triangular; body more or less elongated, the elytra with their outer margins almost parallel. *Daptus Vittatus* is of a pale yellowish colour, with an oblong black spot on each elytron; the head and thorax are more or less clouded with brown or black in some specimens.

This species is about a quarter of an inch in length, and inhabits sandy districts in the vicinity of water in the southern parts of Russia and France.

Daptus in rassetus (Dejean) has the same colouring as the last, but it is of a larger size, being upwards of half an inch in length; it inhabits North America.

DARABGHERD, or DARABJERD, commonly called Darab, is a town in Persia, in the province of Farsistan, about 26° N. lat., and 54° 50' E. long. It was formerly a town of great extent, but like many other towns in Persia it has fallen from its former splendour. But although a great part of it is in ruins it still contains between 15,000 and 20,000 inhabitants. It is on the banks of a small river in an extensive plain, which is intersected with villages and cultivated lands. The town is surrounded with groves of dates, oranges, and lemons; the juice of the lemon is exported to every part of Persia. The tobacco cultivated in its neighbourhood is esteemed for its mildness, and sent not only to Shirauz, and other parts of Persia, but also to India and Arabia. There are some antiquities in its neighbourhood, as the ruins of an aqueduct, some sculptured rocks, and a caravansarai, hollowed in the very heart of a mountain, but their age cannot be ascertained. (Kinneir; Sir W. Ouseley.)

DARDANELLES, The, are fortifications erected on both sides of the Hellespont, which from them take also the name of the Strait of the Dardanelles. This strait, which divides Europe from Asia and unites the sea of Marmara to the Archipelago, extends in a south-west direction between 26° and 27° E. long. and between 40° and 40° 30' N. lat. Its length is upwards of 50 miles, but its width varies. Near the sea of Marmara it is about ten miles across, but it narrows by degrees, so that opposite the town of Gallipoli it is only about two miles wide. This may be considered as the average breadth for the remainder of its extent. Towards the southern extremity it narrows still

more, at some places even to one mile and less. A strong current runs always through it from the sea of Marmara to the Archipelago, and the Turks have erected fortifications at these narrow places for the purpose of rendering it impossible to attack their capital from the side of the Mediterranean Sea. Admiral Duckworth indeed sailed through the strait in 1807, but since that time the fortifications have been improved and increased in number.

The fortifications originally consisted of four castles, two in Europe and two in Asia. Two, called the New Castles, are situated near the entrance of the strait on the side of the Archipelago, where it is more than two miles across. The castle of Europe is called Kilid Bahr, and that of Asia Kum Kalesi; the former is provided with 70 guns and 4 mortars, and the second with 80 guns and 4 mortars. About 18 miles farther to the north-east are the Old Castles; that in Europe, the antient Sestos, is called Sed Bahr; that in Asia, the antient Abydos, Khanuk Kalesi. In the former are mounted 50 guns, and in the second 84. But it seems that the name of Dardanelles is now especially applied to some fortifications erected in modern times between the castles, but considerably nearer to the Old than to the New Castle. In these new works 64 guns are mounted in Europe and 120 in Asia. The number of guns mounted in all these fortifications and some others of less importance is 689, besides 8 mortars.

'Strong as the Dardanelles are,' says Major Keppel, 'where in every direction the eye rests upon guns bearing on a short and very narrow passage, the most dangerous part is the approach to the inner (old) castles. Their strength consists in the position of the castle of Sestos, to which, from the nature of the current and from the banks running far out, a ship must come stem on, and inevitably be raked, without the power of returning more than her bow-guns until just abreast, by which time she would be dreadfully cut up, if the fire were at all well directed.'

The same author states that the batteries are well built, and placed in spots judiciously chosen, and that the greater number of the guns are *à fleur d'eau*; but that they have no carriages, and cannot be pointed; they fire only when a ship covers them. Among them are several immense guns, from which they discharge stone shot. The quantity of powder which these large guns require is enormous: the largest is charged with 320 lbs.

No ship is permitted to pass the forts between sunset and sunrise, and the guns must previously be dismounted and the ports shut.

DARDA'NIA, a town of Troas, on the coast of Mysia, in Asia Minor. It was said to have been founded by Dardanus. (Strabo, p. 592, *a.*; *Iliad*, xx. 216.) The name Dardania was also given to Dacia Mediterranea. [**DACIA**.]

DAR-FUR, a country in Africa, between Bornou and Abyssinia, lying between 11° and 16° N. lat., and between 26° and 30° E. long. Its extent and real boundaries are very imperfectly known.

It may be considered as a large oasis, placed in the south-eastern corner of the Sahara, and divided by deserts of considerable breadth from Dar Berghami on the west, and from Kordofân on the east. The southern part of the country is hilly, and contains valleys with brooks and rivulets which have water all the year round. But the northern part is a level country, partly covered with sand, and in other places by rocks: water is only obtained from wells. During the rainy season it exhibits a fine vegetation, but during seven or eight months in the year the whole district is dried up, all the plants fade away, and even the trees lose their foliage.

The periodical rains commence in the middle of June and last to the middle of September; they are generally very heavy, and fall most frequently from three o'clock till midnight; they are mostly accompanied by lightning. The changes of the wind are not periodical but instantaneous. The greatest heat prevails with a southerly wind, and the greatest quantity of rain falls with a south-east. When the breeze is from north or north-west, it is most refreshing, but it does not generally continue long in that quarter. When southern winds blow the hot air is filled with thick dust.

As soon as the rains begin the agricultural operations commence. The grains raised are wheat, doku, kassob, and sesamum. They plant also beans, kidney-beans, lentils, and some leguminous vegetables peculiar to that part of Africa. Water-melons, together with some other kinds,

abound during the wet season, and also before if they are irrigated. Among the fruit-trees are tamarinds and dates, but the latter are few in number and their fruit small, dry, and destitute of flavour. Browne says that tobacco is indigenous in Dar-fur.

Neither horses nor sheep are numerous. The flesh of the sheep is indifferent, and they are covered with coarse wool, resembling hair, which is wholly unfit for any manufacture: they have not a large tail, like other sheep in this part of Africa. Goats are more numerous. Asses are of small size, resembling those in Great Britain. Cattle form one of the chief branches of wealth, and they are paid as tribute to the sovereign. Camels are very numerous and of all colours and sizes; their flesh is used for food.

The ferocious and wild animals are principally the lion, the leopard, the hyæna, the wolf, and the jackal; the elephant, which is said to gather in herds of four or five hundred, the rhinoceros, the giraffe, the hippopotamus, crocodile, and wild buffalo; no tame buffaloes are found in this part of Africa. Antelopes, ostriches, and civet-cats are also common. Iron seems the only metal which is found in the southern districts; besides alabaster, various kinds of marble and common salt occur here. Nitre abounds, but is not used.

The population of Dar-fur, which Browne thinks cannot exceed 200,000, consists mostly of the descendants of emigrants from the countries along the banks of the Nile, especially Dóngola, Sennaar, and Kordofân. Among them are also some families from Egypt, Tunis, and Tripolis. They use the language of Barabra, though they also speak Arabic. Arabs are also numerous in some parts.

Cobbe, from whence the caravans depart for Egypt, is two miles in length, extending from south to north, but very narrow, and the houses, each of which occupies in its inclosure a large portion of ground, are separated from one another by a considerable space. The town is full of trees of every kind, and contains about 6000 inhabitants, all of them merchants. Other places are Cubcabiâ, in the western district, the depôt of all the merchandise destined for Soodan, and Sweini, and the general resort of the merchants trading to Egypt, both in going and returning.

Dar-fur carries on some trade with Egypt by caravans, which go occasionally, but not every year. They take their route through the desert to Elwah, or the Great Oasis, passing in their way through the small oases, Bir el Malha, Leghea, Selimé, and Sheb. The articles which they bring to Egypt are slaves, camels, ivory, horns of the rhinoceros, teeth of the hippopotamus, ostrich feathers, gum, pimento, tamarinds, and leather sacks for water; also parroquets, monkeys, and guinea-hens, and a small quantity of copper brought from countries lying farther west. They take in return trinkets, cotton cloth, sword blades, small looking-glasses, fire-arms, coffee, silk unwrought, glass beads, copper culinary utensils, fessans, or red caps of Barbary, French cloth, and some silk stuffs of Damascus, Aleppo, &c., shoes of red leather, pepper, writing-paper, a considerable article, and soap of Syria. Hardly anything is known respecting the commercial intercourse between Dar-fur and the countries lying farther west; but it seems to be comparatively considerable, and thence the ivory, ostrich feathers, and slaves, seem to be brought. The inhabitants are Mohammedans, and are governed by a despotic sovereign. (Browne's *Travels in Africa*, which is the only authority.) [See BROWNE.]

DARIC (*Δαρεικός*, *Daricus*), a Persian coin of pure gold, stamped on one side with the figure of an archer crowned, and kneeling upon one knee, upon the other with a sort of quadrata incusa, or deep cleft. Harpocration (*in voc.* *Δαρεικός*) ascribes its origin and name to a Darius of a remote period; but Wesseling (*Observat. Variæ*, 8vo. Traj. ad Rhen. p. 241) and other later writers, upon the authority of Herodotus, give it to Darius Hystaspis, the father of Xerxes, who began his reign B.C. 521. The daric was equivalent in value to the Attic Chrysus (*χρυσός*), and was worth twenty drachmæ of silver: five darics were consequently equal to an Attic mina of silver (Harpocration). Xenophon, in his 'Cyropædia' (vii.), informs us that the daric was a month's pay for a common soldier. Prideaux (*Connect. of Old and New Test.* 8vo. Lond. 1725, i. 183) observes, that in those parts of Scripture which were written after the Babylonish captivity (he refers to Chron. xxix. 7, and Ezra viii. 27), these pieces are mentioned by the name of *Adarkonim*; and in the Talmudists (see Bux-

torf's *Lexicon Rabbincum*, p. 577) by the name of Darkonoth, both from the Greek *Δαρεικός*. The daric was the gold coin best known in Athens; and when we consider the great number which are recorded to have been employed in presents and bribes alone, exclusive of the purposes of traffic, it would seem extraordinary that so few should have reached modern times, if we did not know that upon the conquest of Persia they were melted down, and recoined with the type of Alexander. Very few Persian darics are now to be seen in cabinets. There is one in Lord Pembroke's, which weighs 129 grains; and there are three in the cabinets at the British Museum, weighing about 128½ grains each. Mr. Young, our most eminent dealer in coins, also possesses two, one weighing about 121½ grains, the other 128½; few other darics, it is believed, can be referred to in England. The witticism of Agesilaus (Plutarch, *Apophthegm. Lacon.* xl.) is well known, who, being forced to retire from an invasion of the Persian provinces by the bribery used by the great king, said that 30,000 archers had defeated him.

The silver coins which go by the name of darics are in truth miscalled. They had no such designation in ancient times. The earliest of them, if we may rely upon Herodotus in a passage already referred to (iv. 166), were struck by Aryandes, the Persian governor of Egypt, in imitation of the darics. 'This Aryandes was governor of Egypt, and had been appointed by Cambyses. Some time after, presuming to put himself on an equal footing with Darius, he lost his life in consequence. Hearing by report, and seeing himself, that Darius was desirous to leave some memorial behind him, such as no other king had done, Aryandes followed his example, and met with his reward. Darius took the best gold, and purifying it to the highest degree, struck a coin. Aryandes, being governor of Egypt, did the same in silver; and the silver of Aryandes is now the purest. Darius being informed of what he was doing, put him to death, under the pretence that he was meditating a revolt.' The coining of these darics or Aryandies in silver, however, must have been continued after the time of Aryandes. No fewer than eight specimens of this description are in the cabinets of the British Museum. One, formerly Mr. R. P. Knight's, bears the name of Pythagoras, as Mr. Knight conjectured, a king or governor of Cyprus. Others, which have the figure of the archer crowned on one side, have a mounted horseman on the other. They are generally considered as ancient Persian coins, and are commonly, though without any assignable reason, except as bearing the figure of an archer, called darics.

DARIEN, the GULF of, forms the most southern portion of the Caribbean Sea, extending from 7° 56' to 10° N. lat., between 76° and 78° W. long. Its most southern recess is called the Bay of Candelaria, which begins on the north between Cape Tiburon and Punta Caribana. This latter bay forms a spacious harbour capable of containing all the fleets in the world, and has a good anchorage of from eighteen to thirty fathoms deep, sheltered against every wind, and only subject to a strong sea in the months

when north winds prevail. Not far from the southern extremity of it is the mouth of the Rio Atrato. (Mollien, *App.*)

DARIEN, ISTHMUS of. [PANAMA.]

DARI'US, the name of several Persian kings. Darius I., commonly called Darius Hystaspis, or the son of Hystaspis, belonged to the royal house of the Achæmenidæ, and mounted the throne B. C. 521, after having, with six other conspirators, despatched the usurper Smerdis. It was one day agreed among them, according to Herodotus (iii. 82, 83), that they should assemble on the following morning before sunrise on horseback, and that he whose horse neighed first to the rising sun should be king: the horse of Darius neighed first, and Darius was saluted king (iii. 84-87).

Darius was in fact the founder of the Persian constitution. Countries which Cyrus and Cambyses had only subdued he first organized into a systematic kingdom. He divided his vast empire into twenty satrapies or provinces, and appointed a fixed tribute to be paid, as well as a regular supply to be sent for the provisions of the army and the king's household (iii. 89-96).

A system of communication between different parts of the empire was established by means of couriers stationed at certain distances for the transmission of the royal messages.

Soon after his accession to the throne, Darius was visited by Syloson, the brother of Polycrates, tyrant of Samos, who reminded him of the cloak with which he had obliged him in Egypt, when acting as one of the guards of Cambyses. Darius offered him any reward he would name: he asked to be restored to Samos, and put in possession of the kingdom of his late brother. Darius sent Otanes with an army to Samos, and soon succeeded in reducing the island. Mæandrius, who was in possession of it at the time, was allowed to quit it (iii. 139-141). Meanwhile the attention of Darius was called off to another and more important affair. The Babylonians had revolted, and made great preparations for resistance. Darius marched against them with considerable force, and besieged them for a year and eight months, but without success, till the artifice of Zopyrus put him in possession of the city. Zopyrus, one of the officers of Darius, after cutting off his own nose and ears, and lacerating his body in a frightful manner, went over to the enemy, telling them that this was the treatment he had got from Darius, and he had therefore come over to them that he might aid in taking revenge on the tyrant. The Babylonians received him gladly, and not doubting for a moment the truth of his story, gave him an important post of command, and soon intrusted to him the whole city, which he delivered up to Darius. Darius impaled 3000 of the chief citizens, and destroyed the walls and gates of the city (iii. 150-160). Darius employed the Greek navigator, Scylax of Caryanda, to follow the Indus to the ocean and to survey the country (iv. 44); and the discoveries which he made were followed by the subjugation of a portion of the Indians (iv. 44; iii. 101). One of the principal events in his reign was his expedition against the Scythians. He marched against them with a force which is computed at seven or eight hundred thousand men. A bridge of boats was laid across the Bosphorus, and the work was executed by Mandrocles, a Samian, who received a present from the king as a reward for the skill which he displayed (iv. 85-87). Darius pursued his march through Thrace, across the Danube, to the Don, but met with very ill success, and had great difficulty in escaping eventually. He returned to the Danube, recrossed it, and came back into Asia, leaving Megabazus in Thrace with orders to subdue the Pæones (v. 12-16). Megabazus subdued them and transported them into Asia, where Darius allotted them a district in Phrygia.

In 501 B. C. some disturbances arose in the island of Naxos, which ended in the aristocratical party being obliged to quit the country. They applied to Aristagoras, governor of Miletus, for succour, which he was willing to afford, but was unable to grant without the aid of the Persians. Aristagoras communicated the scheme with splendid promises of success to Artaphernes, the king's brother and governor of Sardis, who, after procuring the king's consent, intrusted a fleet of two hundred ships to the command of Megabates, and ordered it to sail to Miletus to take on board the forces of Aristagoras. After a four months' siege their funds were consumed, and Aristagoras had contracted a debt with the Persian government which it was

wholly out of his power to discharge. An insurrection of the Ionian states, whom he excited to revolt, speedily followed, and ended in the fall of Miletus 494 B. C.

The Athenians had given Aristagoras aid in the revolt, and had thus excited the bitter hostility of Darius, who sent, under the command of Datis and Artaphernes, an army to Attica, where they were opposed and defeated by Miltiades in the plain of Marathon B. C. 490. (Herod. vi., 113-117.) [MARATHON.] The conquered Persians returned to Asia. Darius began to make preparations for another expedition against the Greeks, as well as for reducing the Egyptians, who had rebelled, but he died before the commencement of the war B. C. 485, after a reign of thirty-six years (vii. 4). He appointed his son Xerxes his successor (vii. 3.)

Before he became king, Darius had three sons, two of whom are mentioned (vii. 2-97), Artabazanes and Ariabignes. After his accession he had four sons by Atossa, and several by other wives.

DARIUS II., called Darius Ochus or Nothus, because he was the illegitimate son of Artaxerxes. Soon after the murder of Xerxes II., Darius succeeded in deposing Sogdianus, and ascended the throne himself B. C. 423. By his wife Parysatis he had Artaxerxes Mnemon and Cyrus the younger. Nothing very remarkable occurred during his reign, but some successful wars were carried on under Cyrus and other generals. He died B. C. 404, after a reign of nineteen years, and was succeeded by his son Artaxerxes, who is said to have asked him on his death-bed by what rule he had acted in his administration, that he might adopt the same and find the same success. The king's answer is said to have been, that he had always kept, to the best of his knowledge, the strict path of justice and religion. (Xenophon, *Anabasis*, i. 1; Diodorus, xii. 71; Justin, v. 11.)

DARIUS III., or Codomannus, the last of the Persian monarchs, succeeded Artaxerxes III., B. C. 336, after a short interval, in which Arces, the youngest son of Artaxerxes, was nominally king. Bagoas had poisoned Artaxerxes, and then put Arces on the throne, that he himself might reign in his name: but after two years he deposed him, and put in his place Darius Codomannus. Darius not being so obsequious to his wishes as he desired, he determined to remove him in the same way as he had done with Artaxerxes. The king, however, aware of his design, made Bagoas himself drink the poison which he had prepared for him. Darius was now firmly established on the throne, but had little time to enjoy his security before he found himself opposed by Alexander the Great.

It was in the second year of Darius's reign that Alexander passed over the Hellespont into Asia: he pursued his march till he arrived at the river Granicus (now the Oost-vola), when his first encounter with the Persian army took place. The well-armed and well-disciplined troops of the Macedonians gained a complete victory. Another battle was fought at Issus, in Cilicia, where Darius took the command himself and was utterly defeated. He engaged in person again in a battle at Gaugemela, commonly called the battle of Arbela [ARBELA], and was defeated. After the battle of Issus, Darius's camp was plundered, and his wife, mother, and children, came into the hands of Alexander, who treated them with the utmost consideration and care. Now that Susa, Persepolis, and all his treasures had come into the possession of the conqueror, Darius took refuge in Ecbatana, but was seized by Bessus, the governor of Bactria, who betrayed him in his misfortunes. Both the traitor and his prisoner fled before the march of Alexander, who hastened the pursuit till he came in sight of them, when they fled precipitately; and because Darius would not follow them, Bessus and those about him discharged their darts at him, and left him covered with blood at the mercy of the Macedonians. When the Greeks found in this state he had just strength enough left to ask for some water to drink, it was given him by a Macedonian, whom he requested to return his warm thanks to Alexander for the kindness he had shown to his wife, mother, and children, and to say that he prayed the Gods to prosper him in all his undertakings and to make him monarch of the world.

Alexander himself came up soon afterwards, and was much affected at seeing the king in this deplorable state. He took off his own cloak and spread it over the corpse, which he ordered to be embalmed and sent in a splendid coffin to Sisigambis to be interred with the other monarchs

of Persia. Darius died B. C. 330, in the sixth year of his reign, and the fiftieth of his age. He enjoyed the reputation of a just and humane prince. With Darius ended the empire of Persia, which had lasted for upwards of two hundred years under thirteen kings. (Diodorus Siculus xvii. 5-77; Plutarch, *Life of Alexander*; Justin, x.) [ALEXANDER III.]

DARLINGTON. [DURHAM.]

DARMSTADT, the capital of the grand duchy of Hesse and of the province of Starkenburg, lies in the bailiwick of the same name, in 49° 52' N. lat., and 8° 37' E. long. It is situated on the banks of the small river Darm, between the Main and the Neckar, about ten miles from the Rhine, and also from the commencement of the Bergstrasse, a Roman road leading from Darmstadt to Basle. It was formerly a village, but, under the Emperor Louis the Bavarian, became a town of the principality of Katzenellenbogen, and a castle was erected for its defence. After the extinction of that family it lost much of its importance, until George I., son of the Emperor Philip the Great, made it his residence, since which period it has increased considerably both in extent and consequence.

Darmstadt is divided into the old and new town; the former is inclosed within old massive walls, and has a gloomy uninteresting appearance; the new town, however, although similarly defended, is built in better style, has broad, clean, and well-lighted streets, and handsome houses, although, from the great number of uncovered spots in it, it has a somewhat desolate aspect. The town has six gates; five public squares; the ducal residence (a large edifice, with a library of about 100,000 volumes), the military school, the heir-apparent's palace, a museum of natural history, with a small but choice gallery of paintings and antiques, and the ducal pleasure-grounds; a very handsome opera-house, and a riding-school, the handsomest building in Darmstadt, 320 feet long, 150 broad, and 90 in height, without pillars or other support in the interior; an arsenal, excellent barracks, house of correction, and magazines; the town church, containing the ducal vaults; one Lutheran, one Reformed, and one Roman Catholic church, which is a handsome circular structure on an eminence, with a splendid dome, supported by twenty-eight large columns; one ducal chapel, one synagogue, an orphan asylum, two hospitals, and a large reservoir for supplying the town with water in case of fire. There is likewise the gymnasium, with twelve professors; the pedagogium, a seminary for teachers; the Real school for the education of merchants, mechanics, &c.; an academy of design; a drawing-school for builders; fourteen elementary schools, the town school for boys and girls, a military and a free school; a bible society, freemasons' lodge, &c.

Darmstadt is the residence of the grand duke of Hesse, and the seat of various public boards, and the civil and criminal courts. It contains a population of 24,500 (in 1817, 15,450), who are chiefly dependent for support on the expenditure of the court, public functionaries, and garrison. There are a few manufactures (chiefly of woollens and linens): the remainder of the inhabitants are engaged in tanning, gardening, &c. The environs, especially towards the mountains, are very picturesque, and the soil, which is sandy, is highly cultivated. In the vicinity of Darmstadt is a curious magnetic rock, and Carlshof, an interesting farm, cultivated in the most perfect manner and containing a large nursery of trees. Darmstadt has six fairs every year.

DARNETAL, a town in France, in the department of Seine Inférieure, in the immediate neighbourhood of Rouen, and on a road leading from that city to Beauvais. It is a busy town, with a population of 5572 inhabitants, who are engaged in manufacturing fine woollen cloth, blankets, druggets, and other coarse woollens, cotton yarn, and printed calico. There are also several paper-mills and dye-houses. Rouen is partly supplied with water from a spring at Darnetal.

DA'RNIS (Fabricius), a genus of insects of the order Hemiptera, and family Cercopidae. The species of this genus have the posterior part of the pro-thorax prolonged so as totally to cover the upper part of the abdomen and wings, or nearly so: this portion of the pro-thorax is of the form of an elongated and arched triangle. [CICADELLA.]

DAROO TREE is the *Ficus Sycomorus*, or Egyptian Sycomore; there is a picturesque view of this plant in

Salt's 'Abyssinia,' along with the Ooelisa of Axum. [FICUS.]

DARTFORD. [KENT.]

DARTMOOR. [DEVONSHIRE.]

DARTMOUTH, a seaport, market and borough town, situated on the southern coast of the county of Devon, 30 miles south by west from Exeter and 203 W.S.W. from London.

In antient records this place is called Clifton-Dartmouth-Hardnesse, in fact comprising three adjacent towns. From the convenience of its harbour it was very early a place of some note, and in 1190 was the rendezvous of the fleet destined for the Holy Land. In the beginning of the 13th century it obtained a market and other valuable privileges. It sent two members to parliament from the 14th year of the reign of Edward III. to the passing of the Reform Act, which reduced the number to one. In the reign of Edward I. Dartmouth contributed 31 ships and 800 men towards the naval expedition against France.

Dartmouth was considered an important port during the Parliamentary war, and was strongly contended for by both parties; it was taken by Prince Maurice after a siege of four weeks, and garrisoned by the king's forces; but Fairfax shortly afterwards attacked it in person and took it by storm. The manor was granted by Edward III. to his servant Guy de Brien, and, after several mesne possessors, finally passed into the hands of the corporation.

The limits of the borough comprise 1650 acres, consisting of the parishes of St. Saviour, St. Peter's, and part of Townstall. Dartmouth has no less than 14 charters of incorporation, and also claims to be a borough by prescription. The jurisdiction is exclusive for all offences, except treason and capital felonies. The mayor, recorder, and justices hold quarter sessions, and the magistrates hold weekly petty sessions. The revenue of the corporation is about 1100*l.* a year.

Dartmouth is delightfully situated on a declivity on the west bank of the river Dart. Some of the houses are extremely old and possess some fine specimens of wood-carving; but generally the town is dirty and the streets narrow and ill-paved. The country around is exceedingly beautiful and picturesque, and contains some delightful country seats. A flying bridge has lately been established across the river Dart. The harbour is very safe and convenient, and can accommodate 500 ships. The entrance is between the ruins of Kingswear castle and the fort and church of St. Petrock, where a battery has been erected. The port is under the direction of a governor, appointed by the corporation, and extends from the river Teign to the river Erme, a distance of about 40 miles.

The parishes of St. Petrock, St. Saviour, and of Townstall, which now form the borough of Dartmouth, contain respectively 1035, 2316, and 1246 inhabitants, making a total of 4597.

The trade consists principally in the export of woollen goods and cider, and the import of wine, and formerly of iron. In 1828 there were 348 vessels belonging to the port. Nearly 3000 of the inhabitants are employed in the Newfoundland and other fisheries.

The river Dart is navigable as far as Totness, and its banks are surrounded with beautiful scenery. There are no fairs of any importance at Dartmouth. The market-day is Friday.

The living of St. Petrock is a perpetual curacy: the church is beautifully situated at the entrance of the harbour. St. Saviour is a perpetual curacy annexed to the vicarage of Townstall, in the patronage of the corporation. The interior of the church is highly ornamented. The pulpit is of stone, richly sculptured and gilt, and the screen is beautifully carved. The old oak ceiling is still in a good state of preservation. The living of Townstall is a discharged vicarage also in the patronage of the corporation. All three parishes are in the diocese of Exeter and archdeaconry of Totness. There are places of worship for Baptists, Independents, and Wesleyan Methodists. There are Sunday-schools in each parish supported by subscription. In 1715 there was a French church. There are several charitable bequests for the benefit of the poor and instruction of children: amongst others, Mr. John Lovering, in 1671, founded an alms-house for decayed seamen or their widows; but the house was accidentally burnt down and the charity has been entirely lost. In 1679 Walter Jago, John Haynes, and Arthur Holdsworth, gave a rent-charge of 18*l.* per annum to the parish of St. Saviour, 3*l.* 12*s.* of

which was to be given to a Latin master and 3*l.* 12*s.* to an Arithmetic master. The grammar-school has no further endowment. Newcomen, the inventor of the steam-engine, was a native of Dartmouth.

DARWAR, a district in the province of Bejapore, was formerly part of the territory of the Peishwa, and came into possession of the English in 1818. In the following year there occurred a serious failure of the harvest, accompanied by an epidemic, which carried off one in twenty-four of the population, amounting to 600,000. The revenue of the district was at that time 152,150*l.* [BEJAPORE.]

From a return made by the political agent of the East India Company resident at Darwar in 1825, it appears that there were then in the district 1441 villages, only 150 of which were provided with schools, in which 2351 scholars were instructed; 871 of these learned only reading, writing, and simple arithmetic; 1390 learned to write on sand, or on boards besmeared with a kind of earth called dowlacharam, and 107 were taught to read Persian books.

DARWAR, the capital of the above district, is situated in 15° 28' N. lat., and 75° 8' E. long. It is a fortified town, and was besieged by an allied force of English and Maharatta troops for twenty-nine weeks in 1791, when it surrendered by capitulation. During the operations of the siege the town was nearly destroyed, but has long since been restored.

DARWIN, ERASMUS, an English physician and physiologist, was born at Elton, near Newark, on the 12th December, 1731. After studying at St. John's College, Cambridge, and taking the degree of doctor of medicine at Edinburgh, he established himself as a physician at Lichfield, where he married, and resided till after the death of his first wife, by whom he had three sons. In the year 1781, having again married, he removed to Derby, where he died on the 18th of April, 1802, in the 70th year of his age. He is said to have been a man of an athletic person, and of temperate habits, the advantage of which he lost no opportunity of pointing out to those over whom his influence extended; his biographers give him credit for having done much service to the poor of Lichfield in this respect.

Dr. Darwin claims a place in this work as a general physiologist and a poet. In the year 1781 he published his 'Botanic Garden,' a poem in two books; in 1793, his 'Zoonomia, or Laws of Organic Life,' which was succeeded in 1796 by a continuation of the subject, the whole forming two volumes in 4to.; and in 1800, his 'Phytologia,' or Philosophy of Agriculture and Gardening, in one volume 4to., of rather more than 600 pages. All these works have excited considerable attention; by some they have been extravagantly praised, by others as unreasonably depreciated, and at the present day they are little read or consulted. Nevertheless, they are far from deserving to sink into neglect and oblivion. This author was unquestionably a man of a highly original turn of mind; he was unusually well read in the physics of his day; he had a singular aptitude for seizing and illustrating natural analogies, and above all he was fully impressed with a sense of the important truths of a universal simplicity and harmony of design throughout the whole creation. It is true that his analogies are often imaginary, his theories untenable, and his illustrations overstrained, but many of these errors were inevitable in the state of natural history in his day, and the others are by no means sufficient to overbalance his claims to fame as a clear-sighted, ingenious, and often profound physiologist. Darwin's 'Botanic Garden' is divided into two books, very unequal in size and in merit. The first, which explains the principal phenomena of vegetation, is superior in every respect to the second, which is devoted to what he calls the 'Loves of the Plants,' forming a poetical commentary upon some of the more curious phenomena of vegetable fertilization. That the character of this poem is by no means of a high order must, we think, be on all hands allowed, for its language is often tawdry and tinselly, its similes extravagant, and its machinery fantastical and incomprehensible; but on the other hand it abounds in passages which have never been excelled for their elegant and forcible description of natural objects in poetical language, and it can by no means be admitted that where an author's powers are expended upon an illustration of the laws of any part of the creation, they are applied to mean and insignificant subjects. It is only where he calls to his aid the fancies of the Rosicrucians that he wastes his talent and fatigues

his reader. His 'Phytologia' is remarkable for the number of novel and ingenious ideas which it contains; they were too far in advance of those of his contemporaries to be much esteemed when they appeared, but they are singularly in accordance with many of those opinions which now are either altogether recognized or are under discussion, with a strong probability of being finally adopted. For instance, he particularly insisted upon the close analogy between plants and animals in their functions, showing that the difference between the two kingdoms is the necessary consequence of the difference between their wants, necessities, and habits of life. He urged with great force that every bud of a plant is the seat of a separate and in some measure independent system, that plants are therefore in one sense congeries of individuals living in concert but growing independently; finally, he pointed out the analogy between buds and seeds, showing that the woody part of plants is really analogous to the roots of seeds, and produced by the adhesion of the descending matter of organization which passes downwards from the buds. While, however, we thus give Darwin credit for a rank in science that has hardly been accorded to him before, we are bound to add that his errors were neither few nor unimportant. He was too fond of tracing analogies between dissimilar objects; he readily adopted the ingenious views of others without sufficient inquiry; he had the great fault of being often a credulous collector and a fanciful reasoner, and finally his prose writings are often inexcusably inelegant, ill arranged, and ungrammatical.

DASYORNIS. [THRUSHES.]

DA'SYPUS. [ARMADILLO, vol. ii. p. 350.]

DASYURUS. [MARSUPIALIA.]

DATA, DATUM. A datum is any quantity, condition, or other mathematical premiss which is given in a particular problem. Thus in the question 'to draw a circle which shall have its centre in a given line, and shall touch two other straight lines,' the data are as follows: 1, That the figure described is to be a circle; 2, a certain straight line; 3, that the centre of the circle is to be on that straight line; 4, two other straight lines; 5, that the circle is to touch those straight lines. Data may be divided into two classes, the latter class being the restrictions which it is necessary to place upon the one already described in order that the problem may be possible. Thus the preceding problem becomes absurd when the three straight lines are parallel, unless the line on which the centre of the circle is to lie be midway between the two others. Either then the problem must be proposed with the limitation 'if it be possible,' or an express datum of exclusion must be introduced, namely, that the three straight lines must not be parallel, unless, &c.

In the mere etymology of the word datum all legitimate consequences are data when the premises are data. Thus, given two circles which touch, there are also given two circles which have a common point in the line joining their centres. The book of Euclid known by the name of Data (*δεδομένα*) is the deduction of magnitudes from other magnitudes, not as to what they are, but as to whether they are determined or not. Thus one of the propositions is, 'If a given magnitude be cut in a given ratio, the segments are given.' The preface of Marinus to this book contains a dissertation on the meaning of the term. [EUCLID.]

DATHOLITE, a mineral which contains boracic acid, silica, and lime. It has been found at Arendahl in Norway, and a few other places. It occurs both massive and crystallized in rhombic prisms, the lateral edges and the solid angles of which are usually replaced by planes. The colour of datholite is greyish or greenish white, and it is translucent; its specific gravity is about 3; it yields to the knife; the fracture is imperfect conchoidal; the lustre is somewhat vitreous. According to the analysis of Vauquelin, it consists of

Boracic acid	.	.	21.67
Silica	.	.	37.66
Lime	.	.	34.
Water	.	.	5.5
			98.83

DATISCA'CEÆ, a small natural order of plants allied to Urticaceæ and the other apetalous orders in their vicinity, but distinguished by its inferior ovary with parietal placentæ.

It has unisexual flowers; the males have a calyx of several pieces, and from eight to fifteen stamens; the females have an obsolete superior calyx, and three little recurved stigmas at the apex of an oblong one-celled ovary, with three many-seeded parietal placentæ. The seed-vessel opens at the end like that of *Peseda*; the seeds are enclosed in a finely netted bag, and contain a straight embryo without albumen.

Datisca cannabina, the commonest plant of the order, is an herbaceous diœcious perennial, with stems about three feet high, pinnated leaves with from five to nine ovate-acuminate coarsely-serrated leaflets, and long racemes of flowers collected in clusters in the axils of long linear bracts. It is a native of the southern parts of Europe, where, especially in Candia, it is used on account of its bitter tonic properties as a substitute for Peruvian bark; it also affords a yellow dye.

A male plant of *Datisca cannabina*. A, a cluster of ripe fruit from a female plant.

DATU'RA, a genus of Solanaceous plants, with a funnel-shaped angular five-lobed calyx, a corolla of a similar form, but much larger, and a four-celled capsule, which is either smooth or muricated externally; the base of the calyx moreover adheres to the seed-vessel in the form of a circular disk.

Several species of this genus are known in cultivation, the very large size of their funnel-shaped flowers rendering them conspicuous objects; they have however a nauseous odour, and are only handsome when in flower, for which reason they are not general favourites. They are all exotics, with the exception of the following, in whose properties they coincide.

D. Stramonium, the Thorn-apple, is by no means an uncommon annual upon dunghills, rubbish-heaps, and waste-places near houses. It grows about three feet high, with a light-green stiff stout stem, which is slightly downy near the upper end. The leaves are broad, oval, stalked, sharp-pointed, sinuous, and angular. The flowers are large, white, or occasionally dull light purple, and grow singly from the side of the stem opposite the origin of the leaves; they are erect, and placed upon a very short peduncle. Their calyx is tubular, elongated, a little swollen at the

lower end, with five prominent ribs, ending in as many sharp-pointed lobes; after flowering, it all drops off, except the base, which surrounds the fruit in the form of a circular disk. The corolla is much larger than the calyx, of a similar form, but its lobes are more taper-pointed. There are five stamens, which are inclosed in the tube of the corolla. The ovary is covered with small sharp points, and contains four cells, in each of which is a considerable number of ovules. The style is cylindrical, smooth, and enlarged at the upper end. The fruit is a spiny oval capsule of four imperfect cells, which communicate with each other in pairs. The seeds are brown, kidney-shaped, with a scabrous surface.

This plant is well known, under the name of Stramonium, as a powerful and dangerous narcotic. Its leaves and seeds are the parts employed, and they are found to possess properties similar to those of henbane and belladonna. The leaves are occasionally smoked, especially by country people, as a remedy for asthma; the seeds are employed by thieves to drug the beverage of their victims. In small doses they produce symptoms of frenzy; in larger quantities, stupor and death. The poisonous principle of this and other species is considered a peculiar vegetable alkali, and called Daturine.

Datura arborea and *bicolor*, beautiful arborescent South American plants, the former with long white flowers, and the latter with yellow or scarlet ones, are noble objects in the gardens of this country. They participate in the properties of the true *Daturas*, but they are not now considered to be genuine species, on account of their calyx slitting on one side and remaining permanent around the base of the fruit; they are stationed in a genus called *Brugmansia*.

DATU'RA STRAMO'NIUM, or **THORN APPLE**, an introduced but now frequently self-sown and consequently wild plant, found particularly wherever a garden has been in which it flourished. The leaves and seeds are officinal. The leaves during drying diffuse a stupifying odour, and become deep grayish green; the dried leaves scarcely possess any odour: the taste is disagreeable, saline, and strongly bitter. The seeds are kidney-shaped, flat, about the size of linseed, uneven, nearly black: when bruised the smell is disagreeable and repulsive; taste bitterish and oily; by expression sixteen ounces of fresh seeds yield two ounces of clear fat oil, which has neither taste nor odour. The seeds of the other species of *Datura* are often substituted, perhaps without any great disadvantage. They are also confounded with the seeds of *Nigella Sativa*, which, though black, are smaller, nearly three-cornered, and have an acrid aromatic taste, and in considerable quantity are poisonous like those of Stramonium.

The seeds are used to form the extract; they, as well as the unripe capsules, yield the alkaloid called Datura, which crystallizes from its solution in alcohol or water in colourless shining aggregated prisms; without odour when pure, but when impure possessing a strongly narcotic odour; taste at first bitter, then very acrid, and like tobacco. This is extremely poisonous: one-eighth of a grain can kill a sparrow in less than three hours; and the smallest quantity applied to the eye causes very lasting dilatation of the pupil. At the ordinary temperature of the air it is quite unalterable: it is much less decomposable than hyoscyamia or conia. In a hydrous state it has a strongly alkaline reaction: acids completely neutralize it and form salts, which are procured by solution of daturia in dilute acids and evaporation in a moderate temperature. They are easily crystallizable. Geiger recommends daturia or its salts as a preferable form to any hitherto in use.

Stramonium in small doses causes slight convulsive action about the throat, with dryness of the tongue, disposition to vomit, and general diminution of sensibility, with slight increase of secretion of the skin, mucous membranes, and kidneys, but if the dose be larger, the brain becomes affected, and vertigo, indistinctness of vision, with dilatation of the pupil, disposition to sleep, or coma, but more frequently delirium, are added. The delirium is always peculiar, and the individual manifests a disposition to perform ridiculous actions, or assume absurd positions. If the dose be still larger, and produce fatal effects, the brain is usually found to be much congested, the vessels being gorged with blood. Large bleedings generally save the patient; emetics can rarely be made to act, as is observed when other narcotic poisons have been taken. Stra-

monium is most useful in cases of increased sensibility, particularly in local affections of the nerves; it is decidedly useful in allaying pain of the sciatic nerve, particularly when combined with ipecacuan. It has been recommended in mania, especially when accompanied with lucid intervals, in epilepsy, and hysteria; but with very variable success, probably to be accounted for by the careless preparation of the medicine. It is popularly used for smoking, to allay paroxysms of asthma, but its employment in this way is quite empirical, and regulated by no clear principle. By the action of heat during smoking, an empyreumatic oil is found, similar in properties to that of hyoscyamus.

DATU'RIA, a vegetable alkali, obtained from the seeds of the *Datura Stramonium*, or stramony; it is a colourless crystalline substance, which has an acrid bitter taste, and is very poisonous. It is soluble in about 280 parts of cold and 72 of boiling water, and is readily dissolved by alcohol. It combines with acids, forming salts, which are generally crystallizable, soluble in water, and suffer no alteration by exposure to the air. These salts are decomposed by the alkalis, potash, soda, and ammonia, which precipitate the daturia in the state of colourless flocculi. It does not appear to have been analyzed; but, like the other substances of the same class, there is no doubt of its being composed of hydrogen, carbon, oxygen, and azote.

DAUBENTON, LOUIS JEAN MARIE, a justly celebrated naturalist and zoologist, born at Montbard in Burgundy, on the 29th of May, 1716. The church was his destination, and he was sent to Paris to study theology; but he gave in secret those hours to medicine and anatomy which his father hoped he was devoting to ecclesiastical reading. The death of this parent left him at liberty to follow the path he loved; and, having taken his degrees at Rheims, he returned to Montbard, for the purpose of exercising his profession. But there was a kindred spirit that, happily for zoology, had been connected from infancy with Daubenton. The Comte de Buffon, born at the same place, knew him well in youth, and when, in after life, Buffon was appointed intendant of the Jardin du Roi, his thoughts reverted to Daubenton as the person of all others qualified by his zeal and ability to prosecute those anatomical inquiries, the details of which his own feebleness of sight prevented him from investigating. The count drew Daubenton to Paris in 1742, and in 1745 the office of Curator and Demonstrator of the Cabinet of Natural History was conferred upon a man eminently fitted by his quick discernment, his untiring diligence, and his inexhaustible patience, to fill the situation with the greatest possible advantage to the public. No one can open the '*Histoire Naturelle des Animaux*' without being struck by the multitude and justness of the facts (for he carefully avoided all theory) with which Daubenton enriched that work, and in some degree corrected the fervid imagination of his brilliant coadjutor. But he did this without presuming in the least to draw general inferences: he confined himself strictly to facts; and such was his modesty, that Camper used to say of him that he himself was not aware of the discoveries which he had made. His valuable labours adorned the fifteen first volumes of Buffon's great work in 4to.; and the editions in which this essential part of the publication is wanting, are justly considered as deprived of their fairest proportions. But Buffon in an evil hour suffered his ear to drink the intoxicating poison of fawning flatterers, and published a little edition (in 12mo.), of which Daubenton's labours formed no part. The hint was more than sufficient for the modest Daubenton, and from that time the assistance of Guéneau de Montbeillard and of Bexon in the ornithological department but ill supplied the exquisite dissections and demonstrations which had rendered the former part of the work so highly valuable to the physiologist. For fifty years did Daubenton labour without cessation in enriching and arranging the magnificent collection committed to his charge. He is said to have been the first professor of natural history who gave lectures by public authority in France, one of the chairs of the College of Medicine having been converted into a chair of natural history at his request; it was conferred on him in 1778. The Convention having elevated the Jardin du Roi into a public school, under the title of the Museum of Natural History, he was named Professor of Mineralogy, and retained the professorship as long as he lived. In 1783 he became Professor of Rural Economy at Alfort, and gave lessons in natural history at the normal school in 1795. To him France in a great

measure owes the introduction and successful propagation of the breed of Spanish sheep. In 1799 he was elected a member of the senate, and the alteration in his habits caused by this new dignity is supposed to have hastened his death, which took place after an apoplectic attack of four days' duration in the night of the 31st December and 1st January, 1799 and 1800, when he was nearly 84 years of age.

Daubenton's life, with the exception of the cloud that came between him and Buffon, raised by the weakness of the latter, was a happy one. His hours were spent in pursuits that were dear to him; he was universally respected and beloved, for he was as amiable as he was learned; and his simple habits gave him, notwithstanding his natural weakness of constitution, a long life. Daubenton was married to the authoress of '*Zélie dans le Desert*,' and though his union was in other respects most happy, he left no children.

Lacépède, Cuvier, and Moreau de la Sarte, have justly eulogized this good and great man.

Notwithstanding his incessant occupation at the Museum, he found time to publish much in addition to his writings in the '*Histoire Naturelle*.' He was a contributor to the first *Encyclopédie*, and many of his papers on the natural history of animals and on minerals are to be found in the '*Mémoires de l'Académie des Sciences*,' from 1754 to 1764. Two of his most interesting papers (though all are good) are those of 1762, on fossil bones pretended to be those of a giant, but which Daubenton referred to their true species, and of 1764, on the essential differences between man and the orang outang. His '*Instruction pour les Bergers*,' 1 vol. 8vo., Paris, 1782, his '*Tableau Méthodique des Minéraux*,' 1784, 8vo., and his '*Mémoire sur le premier drap de laine superfine du crû de France*,' which also appeared in 8vo. in 1784, must not be forgotten in a recollection of his works. (*Biog. Universelle*, &c.)

DAUCUS, a rather large genus of umbelliferous plants, with hispid fruit, of a somewhat compressed ovate or oblong form, the primary ridges filiform and quite bristly, the secondary ridges prominent, winged, and divided at the edge into a number of fine teeth or hooks. De Candolle enumerates 38 species, chiefly biennials, but it is doubtful whether several of them are not mere varieties of each other. The only one to which general interest attaches is the *Daucus Carota*. This plant, which grows wild all over Europe in chalky soil, is believed to be the origin of our garden carrot, but there is no record of its having first begun to change its hard wiry juiceless wild root for the nutritious succulent carrot of the gardens. De Candolle gives for the range of the wild plant the meadows and pastures of Europe, the Crimea, and Caucasus, whence it has been transported into China, Cochin China, America, and elsewhere. [CARROT.]

DAUDIN, FRANÇOIS MARIE, the son of a receiver-general of finance, was born at Paris towards the close of the eighteenth century. Nearly deprived of the use of his limbs by natural infirmity, he early devoted himself to the study of the sciences, and more particularly to natural history. His memoirs soon found their way into the '*Magasin Encyclopédique*' and the '*Annales du Muséum d'Histoire Naturelle*,' and he contributed some articles to the '*Dictionnaire des Sciences Naturelles*.' His two principal works are his '*Traité d'Ornithologie*,' which was never finished, and his '*Histoire Naturelle des Reptiles*.' For the first much cannot be said: it is on the second that his fame will rest. Cuvier speaks of the latter as the most complete work on that class of animals which had hitherto appeared. His wife, who is represented as amiable both in mind and person, and as having actively assisted in the composition and illustration of his works, died of consumption; and poor Daudin, whose life, as well as that of his partner, had been long embittered by the deranged state of his affairs, followed her in a few days, before he had attained thirty years of age. He died in 1804, and left no children. (*Biogr. Universelle*, &c.)

DAUNIA. [APULIA.]

DAUPHIN, the title given to the eldest son of the king of France under the Valois and Bourbon dynasties. The origin of the word has been a matter of some dispute. The Counts of Albon and Grenoble are mentioned first in the ninth century as feudatories of the kingdom of Arles; they afterwards assumed the title of Counts of Vienne, and became independent, like other great feudatories. Guy VIII.,

Count of Vienne, is said to have been surnamed Le Dauphin, because he wore a dolphin as an emblem on his helmet or shield. The surname remained to his descendants, who were styled Dauphins, and the country which they governed was called Dauphiné. Humbert II. de la Tour du Pin, the last of the Dauphin dynasty, having lost his only son, gave up his sovereignty by treaty to King Philippe de Valois in 1349, after which he retired to a Dominican convent. (Moreri, and the French historians.) From that time the eldest son of the king of France has been styled Dauphin, in the same manner as the eldest son of the king of England is styled Prince of Wales. Since the dethronement of the elder branch of the Bourbons in 1830, the title of Dauphin has been disused. The last who bore it was the Duke of Angoulême, son of Charles X.

DAUPHINE, a province of France, constituting (with the principality of Orange) one of the thirty-two military governments into which that kingdom was divided before the Revolution. It was on the south-east frontier. In its form it approximated to a triangle, having its three sides respectively opposite to the north-east, south-south-east, and west. On part of the north-east side and on the west side it was bounded by the Rhône, by which it was separated from the district of Bresse, in Bourgogne, on the north-east, and from the Lyonnais and Languedoc on the west: on the south it was bounded by Le Comtat de Venaissin and by Provence, and on the remainder of the north-east side by the crests of the Alps, by which it was separated from Piedmont and Savoy. It now forms the three departments of Isère, Drôme, and Hautes Alpes; but the name continues in use, though a different division has been established by law.

Dauphiné is one of the most mountainous districts in France; branches from the Alps traverse it, and some of the loftiest summits of that mountain system are close upon or within its boundary: no other part of France has points equally elevated. Mont Olan is 13,819 feet, a peak west of Maurin 13,107, and Mont Trois Ellions, east of Grenoble, 12,737 feet. The country is watered by a number of streams, which flow into the Rhône, either immediately, or by the Isère, Durance, and other tributaries. The pasturage is excellent, both in the plains and on the mountains; and the wines good, especially the Hermitage, Côte Rôtie, and St. Peray.

Dauphiné was, under the old regime, subdivided into Haut (upper) Dauphiné and Bas (lower) Dauphiné. Haut Dauphiné comprehended the districts of Les Baronies, Le Gapençois, L'Embrunois, Le Briançonnais, Le Champ-saur, Le Grésivaudan, and Le Royanès or Royanez. Bas Dauphiné comprehended Le Tricastin, or Tricastinois, Le Valentinois, Le Diois, and Le Viennois. Several of these districts took their names from their chief towns. Dauphiné had a provincial tribunal, or parlement, which held its sittings at Grenoble. This city, which may be considered as the capital of Dauphiné, as well as of the subordinate district of Grésivaudan, is on the Isère: it had in 1832 a population of 24,268 for the town, or 24,888 for the whole commune. The other chief towns are Vienne, capital of Le Viennois (population 13,410 for the town, or 14,079 for the whole commune); Valence, capital of Le Valentinois (population 8898 for the town, or 10,406 for the whole commune), both on the Rhône: Romans, on the Isère (population 7677 for the town, or 9285 for the whole commune); Voiron (population 6924); Montelimar, on the Jabron, which falls into the Rhône (population 5816 for the town, or 7560 for the whole commune); Gap, capital of Le Gapençois (population 4572 for the town, or 7215 for the whole commune); Crest, on the Drôme (population 3895 for the town, or 4901 for the whole commune); Bourgoin, on a small stream which flows into the Rhône (population 3447 for the town, or 3762 for the whole commune); Die, capital of Le Diois, on the Drôme (population 3213 for the town, or 3555 for the whole commune); Nions, or Nyons, on the Aigues, which flows into the Rhône (population 2700 for the town, or 3397 for the whole commune); Embrun, capital of L'Embrunois, on the Durance (population 2392 for the town, or 3062 for the whole commune); St. Marcellin, near the Isère (population 2191 for the town, or 2775 for the whole commune): Le Buis, capital of Les Baronies, on the Ouvèze (population 1886 for the town, or 2180 for the whole commune); Pont-en-Royans, capital of Royanès, on the Bourne, a feeder of the Isère; Briançon, capital of Le Briançonnais, on the Gursane, a tributary of

the Durance; St. Bonnet, capital of Le Champsaur, on the Drac, a feeder of the Isère; and St. Paul-Trois-Châteaux, capital of Le Tricastinois, not far from the Rhône.

Dauphiné had two archiepiscopal sees, Vienne (now united with Lyon), established in the second century; the diocese of which comprehended the greater part of Le Viennois, and extended into Le Valentinois, and into Le Vivarais, a district of Languedoc, and included 355 parishes and 10 abbeys; and that of Embrun, established about A. D. 330, which comprehended L'Embrunois and Le Briançonnais, and extended into Provence, and included 400 parishes and one abbey. There were five bishoprics: Valence, established in the third century, the diocese of which comprehended part of Le Valentinois, and extended into Le Vivarais in Languedoc, and included 140 parishes and 4 abbeys: Grenoble, established in the fourth century, the diocese of which comprehended Le Grésivaudan, Le Royanès, and Le Champsaur, and extended into Le Valentinois and into Savoy, and included 334 parishes and 2 abbeys; Die, established A. D. 220, the diocese of which included Le Diois, and extended into Le Valentinois, and into Provence and Le Comtat Venaissin, and included 70 parishes and one abbey; Gap, established in the fifth century, the diocese of which comprehended Le Gapençois, and extended into Les Baronies and into Provence, and included 221 parishes and one abbey; and St. Paul-Trois-Châteaux, the diocese of which comprehended Le Tricastinois, and extended into Provence and into Le Comtat Venaissin, and included 34 parishes and one abbey. Beside these dioceses, those of Lyon (archbishopric) and Belley (in Bugey), extended into Le Viennois; and that of Vaison (in Le Comtat de Venaissin) into Les Baronies. When Expilly published his *Dictionnaire des Gaules et de la France*, A. D. 1764, there were 11 abbeys (including one which had been secularized) and 70 convents, and other religious houses for men, beside 5 houses of the Jesuits, suppressed in 1763; 10 abbeys and 41 convents for women: these establishments contained 1840 men and 1095 women, bound by monastic vows, and enjoyed revenues amounting in the aggregate to 837,200 livres, or nearly 35,600*l.* a year. The Great Chartreuse [CHARTREUSE] was the most important. There were beside 12 general hospitals, and 10 maladreries or hospitals for lepers. It is to be observed, that Expilly gives a very different account of the number of parishes from that given by Prudhomme in *Le Dictionnaire Universel de la France*, and quoted by us above; they must have adopted different principles in drawing up their respective tables. The archbishop of Vienne had for his suffragans the bishops of Grenoble, Die, and Valence; of Viviers in Le Vivarais (Languedoc), and of Geneva or Annecy, and Maurienne in Savoy: the archbishop of Embrun had for his suffragans the bishops of Digne, Glandèves, Grasse, Vence, and Senés, all in Provence, and Nice in Italy. The bishop of St. Paul-Trois-Châteaux was a suffragan of the archbishop of Arles, in Provence; and the bishop of Gap, of the archbishop of Aix, in Provence.

Since the Revolution, the ecclesiastical constitution of the district has been entirely changed; the archiepiscopal dignity of Vienne has been incorporated with that of Lyon; but the conjoint diocese comprehends scarcely any part of the antient Dauphiné: that of Embrun has been annexed to those of Aix and Arles, but no part of Dauphiné is in the conjoint diocese. The bishop of Grenoble, whose diocese comprehends the department of Isère, is a suffragan of the archbishop of Lyon and Vienne; the bishop of Valence, whose diocese comprehends the department of Drôme, is a suffragan of the archbishop of Avignon; and the bishop of Gap, whose diocese comprehends the department of Hautes Alpes, is a suffragan of the archbishop of Aix, Arles, and Embrun. The other bishoprics of Dauphiné have been abolished.

Before the Roman Conquest this country was inhabited by the Celtic tribes, the Allobroges in the north, and in the south the Segalauni, or Sego-vellauni, and the Tricastini, on the banks of the Rhône; the Tricorii and the Caturiges, among the Alps; and the Vocontii in the intermediate space. The Vocontii, the Segalauni, the Tricastini, and perhaps the Tricorii, were the earliest subdued. The Allobroges had been reduced to subjection by C. Pomptinius, the prætor, a short time before Cæsar's arrival in Gaul; but the Caturiges, in the fastnesses of the Alps, preserved their independence, and attempted with the other mountaineers to impede Cæsar's march when he led his forces out of Cisal-

pine Gaul to oppose the Helvetii. (Cæs., *Bel. Gal.*, I., 10.) They were probably subdued in the time of Augustus. In the first division of Gaul into four provinces (by Augustus), Dauphiné was included in the province Narbonensis: when, at a subsequent period, Gaul was subdivided into seventeen provinces, Dauphiné was included mostly in Viennensis, partly in Narbonensis Secunda, and partly in Alpes Maritimæ. Among the principal towns under the Roman dominion were Vienna (Vienne) and Cularo, afterwards Gratianopolis (Grenoble), in the territory of the Allobroges; Valentia (Valence), in the territory of the Segalauni; Dea (Die), in the territory of the Vocontii; and Ebrodunum (Embrun), in that of the Caturiges: Vienna, Valentia, and Dea, were colonies. Upon the downfall of the Roman empire, Dauphiné formed part of the kingdom of the Burgundians [BURGUNDIANS]; and upon the overthrow of that kingdom became subject to the Franks. It suffered from the ravages of the Saracens in the time of Charles Martel, and formed part of the kingdom of Bourgogne Cisjurane, founded by Boson near the end of the ninth century. [BOURGOGNE.] In the course of the eleventh century, or even earlier, many feudal principalities were formed in Dauphiné, the more powerful among which were called counties, the others baronies. The counts of Albon acquired the predominance among these nobles, and in course of time gained possession of Le Grésivaudan, Le Viennois, Le Gapençois, L'Embrunois, and Le Briançonnais. Guy VIII., who died about the middle of the twelfth century, was the first who had the title of Le Dauphin; his successors retained it, and insensibly the title of Count of Albon was lost in that of Dauphin of Le Viennois, and the country acquired from this new title of its lords the name of Dauphiné. These Dauphins owed feudal subjection to the Germanic empire, with which the crown of Bourgogne had been united. The Dauphin, Humbert II., by treaties made in the years 1343-49, disposed of his states in favour of the king of France. He nominated as Dauphin, by the treaty of 1343, the second son of Philippe VI. (de Valois), then king of France; so that the common notion that he stipulated that the eldest son should bear the title is erroneous. The territory thus ceded to the French crown comprehended the districts enumerated above as belonging to the counts of Albon: the other parts of Dauphiné are subsequent acquisitions. (Expilly, Prudhomme, *Dict. Universel de la France*.)

DAUPHINE' D'AUVERGNE, a small territory of Auvergne, ceded to Guillaume IV., Count of Auvergne, when deposed from his county by his uncle Guillaume l'Ancien (the elder). Vodable, a small town near Issoire, was the capital.

D'AVENANT,* WILLIAM, was born at Oxford in 1605. His father kept the Crown Inn there, and some have gathered, from Wood's words, hints of a connection having existed between his mother and Shakspeare, who frequented that place of entertainment. He was entered at Lincoln College, Oxford; but it does not appear that he took a degree. He then became page to the duchess of Richmond, and was afterwards in the family of Lord Brooke, the poet. In 1637 he succeeded Ben Jonson as laureat; and in 1641 was accused by the parliament, and forced to retire to France. Two years after, he was knighted by Charles, at the siege of Gloucester; but in 1646 we find him again in France, a Roman Catholic, and in the employ of Henrietta. Being taken prisoner at sea in 1651, he only escaped being tried for his life by the intercession of some friends, among whom are said to have been Milton and Whitelocke. His works consist of dramas, masques, addresses, and an unfinished epic called Gondibert, which he dedicates to Hobbes. The only work for which he is now remembered is an alteration of the *Tempest*, in which he was engaged with Dryden; 'and marvellous indeed is it that two men of such great and indubitable genius should have combined to debase and vulgarize and pollute such a poem; but, to the scandal of the English stage, it is their *Tempest*, and not Shakspeare's, which is to this day represented.' (Southey.) He appears to have been the first to mix the English drama with the French heroic play, and to introduce the examples of moral virtue 'writ in verse, and performed in recitative music.' (Dryden.) As he established a theatre as early as 1657, the times might be partly in fault, but his long residence in France had probably

* Or Davenant: a joke in Wood's 'Athen. Oxon.' renders it probable that the alteration was his own.

influenced his taste. He died in 1668, and was buried in Westminster Abbey. (Wood's *Athen. Oxon.*; *Biogr. Brit.*; Southey's *British Poets.*)

DAVENTRY. [NORTHAMPTONSHIRE.]

DAVID. [PSALMS.]

DAVID, JACQUES LOUIS was born at Paris in 1750. In 1774 he went to Rome to study; he returned to France ten years afterwards, and attained considerable reputation, both as an historical and portrait painter. Upon the breaking out of the revolution he threw himself amongst the foremost ranks of the revolutionists. He was the intimate friend of Robespierre, and was appointed manager of all the spectacles and allegorical shows of the republic. He proposed to construct a colossal figure of the people out of the ruins of the statues of the kings, to be placed on the Pont-Neuf, but never proceeded farther than a model, from which, however, the design for the reverse of the republican coin was taken, which was used several years. When Robespierre, anticipating his downfall, expressed himself ready to die the death of Socrates, David, who was present, exclaimed, 'Robespierre, if you will drink the hemlock I will drink it also.' In 1794 he was denounced, and imprisoned, altogether for about a year; but was ultimately liberated, and appears thenceforward to have taken a less prominent part in political matters. He was appointed principal painter to the National Institute. In 1815 he was banished from France with those who had voted for the death of Louis XVI., and took up his abode in Brussels, where he died December 29, 1825. Many anecdotes of his cruelty during the revolution are related by his enemies, but they are not well authenticated; others, in proof of his patriotic magnanimity, are scarcely better established. He appears in truth to have been a man of narrow capacity, and of a warm but not malicious disposition. He is described as being afflicted with a tumour in his jaw, which disfigured his appearance, and so disturbed his utterance that he could not speak ten words in the same tone. To this imperfect speech he added a blustering manner.

David is said to have expressed a wish, that, if an Athenian were to revisit the earth, he might take him for a Greek painter. This is the key to his style, which is a servile imitation of the Greek sculptures; his figures are like statues coloured and put in motion; his drawing is correct, and his composition classical; but his design is constrained and artificial, with a hard outline and harsh colour. The 'Rape of the Sabines' is considered one of the best of his works, which are chiefly at Paris. His portrait of Napoleon is well known.

DAVID'S, ST., a city and parish in the hundred of Dewisland, in the western extremity of Pembrokeshire. It was antiently large and populous, and during the middle ages was the resort of a great number of pilgrims. At present its appearance is that of a poor village, the houses, excepting those of the clergy, being mostly in a ruinous state. The locality is lonely, and the neighbouring district wild and unimproved; but it is still an interesting place as the seat of a large episcopal see, with a fine cathedral and the remains of other magnificent religious edifices. The situation is near the rocky promontory called St. David's Head, on a declivity, a mile from the northern shore of St. Bride's Bay, 16 miles north-west of Haverfordwest, 26 north-west of Pembroke, and 270 west of London. In 1831 the population of the parish, of which the Isle of Ramsay constitutes a part, was 2388. Druidical remains are numerous in the neighbourhood, consisting of sepulchral heaps of stones, barrows, tumuli, holy wells, and some antient fortifications. It is said that a church and monastery were first founded here by St. Patrick about A.D. 470. It is certain however that in the first period after the introduction of Christianity into Britain, three archbishops' seats were appointed, namely, London (transferred afterwards to Canterbury), York, and Caerleon, in the county of Monmouth, and that this last was removed about A.D. 519, in the reign of King Arthur, to Mynyw (called by the Romans Menevia), which received the name of St. David's in honour of the archbishop and saint, by whom the transfer was accomplished. Hence the appellation of *Menevensis*, assumed by the bishops of this see, which was the metropolitan and archiepiscopal see of Wales until A.D. 930, when Sampson, the last of twenty-five archbishops, withdrew to Brittany, and carried with him his clergy and the sacred pall of office. (See a description of this holy ephod by Cressy, l. 35, c. 15.) His successors continued however to administer consecra-

tion to the priesthood until the reign of Henry I., when Bishop Bernard acknowledged subjection to the see of Canterbury. The diocese of St. David's contains the entire counties of Pembroke, Caermarthen, Brecknock, and parts of Radnor, Monmouth, Hereford, Montgomery, and Glamorgan. The ecclesiastical corporation consists of a bishop, four archdeacons, a precentor, chancellor, treasurer, nineteen prebendaries, eight vicars choral, four choristers, and several subordinate officers. On the south side of the city, towards the sea-shore, stands the cathedral, the episcopal palace, and college of St. Mary, in ruins, and several other buildings for the residence of the clergy and other appropriate uses. This group occupies a spacious area called The Close, which is surrounded by a lofty wall about a mile in circumference, having four entrances, north, south, east, and west. The principal gate is the eastern, between two massive towers, one sixty feet high. The little river Alan runs through the area, and was crossed by a marble bridge, worn and polished by the pilgrims' feet. Though great damage was done to these edifices by the puritan fanatics of the seventeenth century, their former magnificence, when the episcopal power was equivalent to sovereignty, is apparent in all that remains. The bishop's palace was the most magnificent in the kingdom, the kitchen and cellars being no less admirable than the state apartments. The first cathedral, from its nearness to the sea, was often plundered, and at last was burnt and destroyed by Danish and Norwegian pirates in 1087. The architecture of the present structure, which was erected by Peter, the forty-ninth bishop, is Norman, blended with the richly-pointed Gothic. It is cruciform, 307 feet in length, with a lofty square tower at the west end, a nave, choir, transepts, side aisles, and lateral chapels, one of which is roofed with slabs of freestone. The rood-loft, screen, and roof, which is of Irish oak, are specimens of great architectural skill. The choir is very lofty, containing twenty-eight stalls and a curious moveable pulpit. The bishop's throne is of exquisite workmanship, and resembles that in Exeter cathedral. An altar-tomb, of the son of Owen Tudor, is similar to that of Prince Arthur in the cathedral of Worcester. Numerous antiquarian relics are collected and preserved in the building. In the walls and floor are many sepulchral monuments of the early bishops of the see, as Giraldus Cambrensis, Anselm, Gower, &c. The most antient is that of Rhys ap Gruffyd, prince of South Wales, A.D. 1196; and the most venerated is the shrine of the Archbishop St. David, the tutelary saint of Wales. During many ages it was visited by innumerable pilgrims, among whom were many nobles and kings. William the Conqueror paid his devotions in 1077, Henry II. in 1171, and Edward I. and Queen Eleanor in 1284. The shrine has four recesses for the deposit of the offerings of the pilgrims, who at once relieved their consciences and their pockets. It was ordained by Pope Calixtus that two pilgrimages to St. David's should be accounted equivalent in efficacy to one to Rome: 'Roma semel quantum dat bis Menevia tantum.' The handsome college of St. Mary was founded in 1365 by John of Gaunt. The chapter-house contains a school-room for the instruction of the choristers, and an elegant dining-room, with kitchen and cellars, for the use of the canons when they assemble to audit the accounts of the see. The bishop of St. David's formerly possessed several other palaces and manor-houses in the counties of Pembroke, Cardigan, and Brecknock. The present episcopal residence is at Abergwilly, near the city of Caermarthen, in a noble palace rebuilt by Bishop Burgess. Among his distinguished predecessors in the see have been Dr. Davies, a translator of the English Bible at the Reformation, and Drs. Laud, Bull, Louth, and Horsley.

(Tanner's *Notitia Monastica*, p. 717; Dugdale's *Monasticon*, vol. vi., p. 1301; Fenton's *Pembrokeshire*; Bishop Burgess's *Vindication*, &c., 4to., 1812; *Life of St. David* in *Acta Sanctorum Martiri*, tom. i., p. 39; Brayley and Britton's *Beauties of Wales*, vol. xviii., p. 821-840. The Harleian MS., No. 1294, contains the statutes of the cathedral, and documents relating to its possessions.)

DAVID'S DAY, ST., March 1. St. David, archbishop of Menevia, now called from him St. David's, in Pembrokeshire, lived in the fifth and sixth centuries of the Christian æra; Pits tells us that he died at the age of 146 years. He is said, in the days of the memorable Arthur, to have gained a victory over the Saxons, his soldiers during the conflict, for distinction and as a military colour, wearing

leeks in their caps. In memory of this fight the Welsh still wear the leek on St. David's Day; and it is to this that Shakspeare alludes in 'Hen. V.,' act v. sc. 1, when he makes Gower upbraid Pistol for mocking 'at an antient tradition, begun upon an honourable respect, and worn as a memorable trophy of predeceased valour.' (See Brand's *Popular Antiq.* 4to., vol. i. p. 86; Brady's *Clavis Calendaria*, 8vo. Lond. 1812, vol. i. p. 228, &c.)

DAVIS, JOHN, a celebrated navigator of the sixteenth century, was born at Sandridge, near Dartmouth in Devonshire, and distinguished himself by three voyages for the discovery of a north-west passage, which he undertook between 1585 and 1587. He discovered the strait, which bears his name, and sailed along the coast of Greenland as far as 72° N. lat., but was not able to approach the opposite coast, on account of the numerous icebergs which lined it north of the Polar Circle. He afterwards made five voyages to the East Indies, and was killed in the last (1605) in the strait of Malacca, by some Japanese, as it is reported. He published an account of his second voyage to the north-west, and of one to the East Indies.

DAVIS'S STRAIT unites Baffin's Bay to the Atlantic, extending between Greenland on the east and Cumberland island on the west, in a northern direction. Its extent is not well determined. Navigators commonly understand by this name the sea extending west of Greenland from Cape Farewell (60° N. lat.) to Disco Island (70° W. lat.) Its narrowest part is near the Polar Circle, where it is about 200 miles across. It is the principal resort of the whalers, the fish being more numerous here than in other seas near the pole. But the immense icebergs, which even in summer line the western coasts of the strait, and the violence of the currents, render these voyages very dangerous. Many of the icebergs rise some hundred feet above the level of the sea, and the whalers which arrive at the end of April or in the beginning of May find the whole strait blocked up by a barrier of icebergs between Cape Walsingham and the Greenland coast. The current, which runs along the eastern coast of Greenland, turns round Cape Farewell and continues along the western coast of Greenland, nearly up to the Polar Circle, where it crosses the strait to Cape Walsingham and continues in a southern direction to Labrador and Newfoundland. By this current the immense icebergs of Davis Strait are carried down to the centre of the Northern Atlantic, where they sometimes are met with as far as 40½ N. lat. The countries on both sides of the strait rise in rocky mountains to a considerable elevation, and exhibit a very scanty vegetation. They are inhabited by the Esquimaux.

DAVISON, SECRETARY. [ELIZABETH.]

DAVITE, a name given to a sulphate of alumina, found in a warm spring which contains sulphuric acid, near Bogota in Columbia. It occurs massive, is of a fine fibrous structure, a white colour, and silky lustre. It is very soluble, and has a very astringent taste.

DAVY, SIR HUMPHRY, was born at Penzance in Cornwall, on the 17th of December, 1778. His ancestors had long possessed a small estate at Varfell, in the parish of Ludgvan. His father was a carver in wood. According to Dr. Paris, one of Sir Humphry's biographers, his father was not remarkable for any peculiarity of intellect; and his mother appears to have been a very respectable woman, who conducted herself, according to Dr. John Davy, the brother of Sir Humphry, so as to gain the regard and good will of every one. At the time of his father's death Humphry was sixteen years old; but his mother lived to witness the rapid progress made by her son in the various departments of chemical science. In speaking of his early days, Dr. Davy admits that many boys have shown precocious indications of talents superior to his; 'there belonged, however, to his mind,' he adds, 'it cannot be doubted, the genuine quality of genius, or that power of intellect which exalts its possessor above the crowd, and which, by its own energies and native vigour, grows and expands, and comes to maturity, aided indeed and modified by circumstances, but in nowise created by them.' It appears that in his early youth he had a vivid and fertile imagination, and was fond of poetry, and his brother has preserved several favourable specimens of his poetic talent. He does not appear to have been fortunately placed at school in the first instance; but he was afterwards, till he was fifteen years of age, with Dr. Cardew, whose school he quitted in 1793. Here he appears to have made considerable pro-

gress in learning, but certainly not such as gave any indication of his future eminence.

In the beginning of the year 1795 he was apprenticed to Mr. Borlase, a surgeon and apothecary of Penzance, where he appears to have laid down an extensive plan of study, not merely of the sciences which related to his profession, but the learned languages, mathematics, history, &c. Dr. Davy states that he is not able to give a precise account of the nature and extent of his medical studies; but in the fourth year after he had commenced them he was considered competent by Dr. Beddoes to take charge of an establishment which he had founded at Bristol under the name of the Pneumatic Institution; this was in 1798, when he was scarcely twenty years old.

In the following year Dr. Beddoes published a work, entitled 'Contributions to Physical and Medical Knowledge, principally from the West of England.' Among these were contained 'Essays on Heat, Light, and the Combinations of Light, with a new Theory of Respiration; on the Generation of Oxygen Gas, and the Causes of the Colours of Organic Bodies. By Humphry Davy.' These essays, his first publication, his brother characterizes 'as the bold attempts of an original and enterprising mind,' and observes that they 'bear the stamp at the same time of youth and of genius, in the faults of the one and the redeeming qualities of the other.' Most of the peculiar views developed in these essays were speedily abandoned by the author; and his brother admits that many of the speculations, he might perhaps have said most, were wild and visionary, and adds, what will be readily admitted, 'that the wildest of them are most natural to a young mind just entering on the twilight of physical science, gifted with high powers and a vivid imagination.'

His next recorded experiments relate to the existence of silica contained in various plants, especially in the epidermis of cane; and in 1800 he published in one volume 8vo. a work entitled 'Researches, Chemical and Philosophical, chiefly concerning Nitrous Oxide and its Respiration.' In this work, which contained the details of numerous highly interesting experiments, he has minutely detailed the extraordinary effects produced both upon himself and others by respiring nitrous oxide, a gas till then deemed irrespirable. This work also contains an account of some extremely hazardous experiments which he made upon himself in breathing carburetted hydrogen, carbonic acid gas, azote, hydrogen, and nitric oxide; in these dangerous trials his life was more than once nearly sacrificed.

In 1801 Davy came to London, and on the 25th of April he gave his first lecture at the Royal Institution. He began with the history of galvanism, detailed the successive discoveries, and described the different methods of accumulating it; and on the 31st of May, 1802, he was appointed professor. From the year 1800 to 1807 a great variety of subjects attracted his attention, especially galvanism and electro-chemical science; the examination of astringent vegetable matter in connection with the art of tanning, and the analysis of rocks and minerals with relation to geology and to agricultural chemistry. In November, 1807, his second Bakerian lecture was read, in which he announced the most important and unexpected discovery of the decomposition of the fixed alkalis by galvanism, and of the metallic nature of their bases, to which he gave the names of potassium and sodium. Dr. Paris has well observed that 'Since the account given by Newton of his first discoveries in optics it may be questioned whether so happy and successful an instance of philosophical induction has ever been afforded as that by which Davy discovered the composition of the fixed alkalis.' From the year 1808 to 1814, the following papers by Davy were read before the Royal Society, and published in their 'Transactions':—

'Electro-chemical Researches on the Decomposition of the Earths; with Observations on the Metals obtained from the Alkaline Earths, and on the Amalgam procured from Ammonia,' read June 30th, 1808.

'An Account of some New Analytical Researches on the Nature of certain Bodies, particularly the Alkalis, Phosphorus, Sulphur, Carbonaceous Matter, and the Acids hitherto uncombined; with some general Observations on Chemical Theory,' December 13th, 1808.

'New Analytical Remarks on the Nature of certain Bodies; being an Appendix to the Bakerian Lecture for 1808,' February, 1809.

'The Bakerian Lecture for 1809; on some new Electro-

chemical Researches on various Objects, particularly the Metallic Bodies, from the Alkalis and Earths, and on some Combinations of Hydrogen,' November 16th, 1809.

'Researches on the Oxymuriatic Acid, its Nature and Combinations, and on the Elements of Muriatic Acid; with some Experiments on Sulphur and Phosphorus,' July 12th, 1810.

'The Bakerian Lecture for 1810, on some of the Combinations of Oxymuriatic Acid Gas and Oxygen, and on the Chemical Relations of those Principles to Inflammable Bodies,' November 15th, 1810.

'On a Combination of Oxymuriatic Gas and Oxygen Gas,' February 21st, 1811.

'On some Combinations of Phosphorus and Sulphur, and on some other Subjects of Chemical Inquiry,' June 18th, 1812.

'On a new Detonating Compound,' Nov. 5, 1812.

'Some further Observations on a new Detonating Substance,' July 1st, 1813.

'Some Experiments and Observations on the Substances produced in different Chemical Processes on Fluor Spar,' July 8th, 1813.

'An Account of some new Experiments on the Fluoric Compounds; with some Observations on other Objects of Chemical Inquiry,' Feb. 13th, 1814.

After the enumeration of these important subjects, we cannot do better than refer to them in the words of his brother and biographer. 'I shall not,' says Dr. Davy, 'attempt an analysis of these papers; I shall give merely a sketch of the most important facts and discoveries which they contain, referring the chemical reader to the original for full satisfaction. After the extraction of metallic bases from the fixed alkalis, analogies of the strongest kind indicated that the alkaline earths are similarly constituted; and he succeeded in proving this in a satisfactory manner. But owing to various circumstances of peculiar properties, he was not able, on his first attempts, to obtain the metals of these earths in a tolerably pure and insulated state for the purpose of examination. On his return to the laboratory after his illness, this was one of his first undertakings. He accomplished it to a certain extent, by uniting a process of MM. Berzelius and Pontin, who were then engaged in the same inquiry, with one of his own. By negatively electrifying the earths, slightly moistened, and mixed with red oxide of mercury, in contact with a globule of mercury, he obtained amalgams of their metallic bases; and by distillation, with peculiar precautions, he expelled the greater part of the mercury. Even now, in consequence of the very minute quantities of the bases which he procured, and their very powerful attraction for oxygen, he was only able to ascertain a few of their properties in a hasty manner. They were of silvery lustre, solid at ordinary temperatures, fixed at a red heat, and heavier than water. At a high temperature they abstracted oxygen from the glass, and at ordinary temperatures from the atmosphere and water, the latter of which in consequence they decomposed.

'The names he proposed for them, and by which they have since been called, were barium, strontium, calcium, and magnium, which he afterwards altered to magnesium.

'The same analogies were nearly as strong applied to the proper earths; and he attempted their decomposition in a similar manner, but not with the same success. By the action of potassium proof was obtained that they consist of bases united to oxygen; but whether these bases were inflammable substances merely, or metallic inflammable substances, was yet a problem, which has since been solved by the labours of Wöhler, Bussy, and Berzelius. Analogy was in favour of the latter inference, as was also the circumstance that the bases of these earths are capable of entering into union with iron; and this has been confirmed by the inquiries just mentioned, as regards the majority of them, all but the basis of silica, which yet remains doubtful.

'The application of these facts to geology was full of promise; and he indulged in the hope that they might serve to explain not only some of the most mysterious phenomena of nature, as earthquakes and volcanoes, and the combustion of meteoric stones and falling stars, but might ultimately lead to a general hypothesis of the formation of the crust of the earth.'

His ideas on this last subject, which he afterwards in great measure relinquished, may be seen in Dr. Davy's *Life of Sir Humphry*, vol. i., p. 397.

After effecting the decomposition of the fixed alkalis,

Davy, reasoning from analogy, conjectured that ammonia might also contain oxygen; and his first experiments were favourable to this supposition; but they contained a fallacy. In his various papers on 'oxymuriatic acid and its compounds' he establishes the views of Scheele respecting its nature, and proves that the reasoning of Berthollet, which had generally been admitted by chemists, was fallacious. He shows that oxymuriatic acid is not a compound, as supposed of muriatic acid and oxygen, but an undecomposed body, to which, on account of its green colour, he gave the name of chlorine. In 1810 he published the first volume of his '*Elements of Chemical Philosophy*,' which, although they bear marks of haste, contain much interesting matter: no further portion of this work was printed. His '*Elements of Agricultural Chemistry*,' which appeared soon after, is a work containing much useful matter, and replete with sound and practical views of the subject.

One of his greatest inventions was that of the miner's safety-lamp, the first paper in relation to which appeared in the *Philosophical Transactions* for 1815, and the last in 1817.

Sir Humphry became President of the Royal Society in 1820, and he continued to contribute papers on subjects of great interest for some years. Among the most curious of these, and full of promise as to utility, were those which related to the modes of protecting the copper sheathing of ships; from causes however which even his sagacity could not foresee, the plan proved abortive.

We have thus given a very imperfect and slight sketch of the discoveries of this very extraordinary man and eminent chemist; a list of his works, or at any rate, the principal of them, will be found at the end of Dr. Paris's *Life of him*. With respect to his philosophical character, the parallel which has been drawn between him and Dr. Wollaston by the late Dr. Henry, while it does justice to both, presents the powers of Davy in a strong and clear point of view, and in the language of one who was deeply versed in the sciences of which he is speaking, and intimately acquainted with the philosopher whose portrait he draws.

'To those high gifts of nature which are the characteristics of genius, and which constitute its very essence, both these eminent men united an unwearied industry and zeal in research, and habits of accurate reasoning, without which even the energies of genius are inadequate to the achievement of great scientific designs. With these excellencies, common to both, they were nevertheless distinguished by marked intellectual peculiarities. Bold, ardent, and enthusiastic, Davy soared to greater heights; he commanded a wider horizon; and his keen vision penetrated to its utmost boundaries. His imagination, in the highest degree fertile and inventive, took a rapid and extensive range in the pursuit of conjectural analogies, which he submitted to close and patient comparison with known facts, and tried by an appeal to ingenious and conclusive experiments. He was endued with the spirit and was a master of the practice of the inductive logic; and he has left us some of the noblest examples of the efficacy of that great instrument of human reason in the discovery of truth. He applied it not only to connect classes of facts of more limited extent and importance, but to develop great and comprehensive laws, which embrace phenomena that are almost universal to the natural world. In explaining these laws he cast upon them the illumination of his own clear and vivid conception; he felt an intense admiration of the beauty, order, and harmony which are conspicuous in the perfect chemistry of nature; and he expressed those feelings with a force of eloquence which could issue only from a mind of the highest powers and the finest sensibilities.' (*Elements of Chemistry*, 11th edition.)

Davy was knighted on the 8th of April, 1812, and on the 11th of the same month he married Mrs. Apreece, the widow of Shuckburgh Ashby Apreece, Esq., eldest son of Sir Thomas Apreece; this lady was the daughter and heiress of Charles Kerr, of Kelso, Esq., and possessed a very considerable fortune. He was afterwards created a baronet. He died on the 28th of May, 1829, at Geneva.

DAVYNE, a silicious mineral found in cavities in some of the masses ejected from Vesuvius; the primary form is a rhomboid, but it occurs in regular hexagonal prisms, with the terminal edges truncated. Its fracture is conchoidal; cleavage parallel to the planes of the hexagonal prism. It is transparent, colour white or yellowish brown. Streak white, lustre vitreous, pearly upon the cleavage planes. Hardness, 5.0, 5.5.; specific gravity, 2.4.

DAWES, RICHARD, was born at Market-Bosworth in the year 1708. His first teacher was Anthony Blackwall, the well-known author of *The Sacred Classics*, after which he spent some time at the Charter House, and went to Emanuel College, Cambridge, in the year 1725; he was elected fellow in 1731. In 1736 he published a specimen of a translation of 'Paradise Lost' into Greek hexameters, which proved, as he afterwards admitted (*Pref.* to his *Miscellanea Critica*), that he was then very insufficiently acquainted with the Greek language. He became master of the grammar-school at Newcastle-upon-Tyne in 1738; but his disagreeable manners diminished the number of his scholars, and he resigned the situation in 1749. In his latter days his principal employment was rowing in a boat on the Tyne; he died at Haworth 21st of March, 1766. The work on which his fame rests is his '*Miscellanea Critica*,' published at Cambridge in 1745, which places him in the same class with Bentley and Porson as a verbal Greek critic. The work is divided into five sections, of which the first contains some emendations of Terentianus Maurus; the second is a specimen of the want of accuracy in the Oxford edition of Pindar; in the third are some general observations on the Greek language, to which are added some emendations of Callimachus; the fourth is a short discussion on the Digamma; and the fifth is devoted to the illustration of Aristophanes. The leading characteristic of the scholarship of Dawes is a proneness to rash generalization; and though it has been termed the scholarship of observation, it must be admitted that Dawes is too apt to form general rules from an insufficient number of passages, and consequently that his system scarcely deserves that title. Hardly one of the syntactical rules which Dawes has laid down has been admitted as unexceptionable; and some of them have been completely overthrown by the number of passages in which they are violated. The authority of the '*Miscellanea Critica*' was however so great for some twenty or thirty years after its publication, that many readings supported by MS. authority were altered to meet the canons in that book. The violent animosity which Dawes everywhere shows towards Bentley is only to be accounted for by the universal dislike which that great scholar had incurred during his quarrels with Trinity College, about the time when Dawes was a young member of the university. The best editions of the '*Miscellanea Critica*' (which may now be considered as superseded by the advances which Greek scholarship has made during the last thirty years) are those by Burgess, Oxon. 1781, and by Kidd, Cantabr. 1817, in which specimens of his other writings may be seen.

DAWLISH. [DEVONSHIRE.]

DAX, a town in France, in the department of Landes. It is on the south-east bank of the Adour, just to the left (across the river) of the high road from Paris by Bordeaux to Bayonne: 502 miles from Paris, 124 from Bordeaux, and 37 from Bayonne, in 43° 42' N. lat., 1° 3' W. long.

This town is situated in a beautiful plain. It is well laid out, and not badly built: the remains of the antient ramparts and of the towers by which they are flanked show traces of Roman work. The waters for which the town is famous rise out of the earth at the bottom of a large basin, about thirty feet square, and two and a half to three feet deep, paved at the bottom and sides, and situated in the centre of the town; they are inodorous and insipid, and so hot that the hand cannot be held in them. The temperature of the water in the basin is about 56° of Réaumur or 158° of Fahrenheit; but a thermometer plunged into the pipe by which the waters enter the basin, rises to 66° of Réaumur or between 180° and 181° of Fahrenheit. The vapour which rises from this basin, condensed by the cold morning air, sometimes forms a dense mist, which envelops the whole town. The waters are not used medicinally; some laundresses use them, and some bakers for making bread. There are however in another part of the town mineral waters which are used in the cure of rheumatism, but not to any great extent. The cathedral is not remarkable. There are an antient episcopal palace, a high school, and an hospital: also an agricultural society, and a small museum of natural history. There is a bridge over the Adour, and some pleasant public walks along the bank of the river. The inhabitants, who in 1832 amounted to 4716, carry on a considerable trade with Bayonne in the produce of the neighbouring districts,—wines, liqueurs, hams, resin,

and wool. There is a considerable weekly market for corn and cattle.

Dax is of great antiquity: its mineral waters were known to the Romans, who called it *Aquæ Augustæ* (Pliny), and *Aquæ Tarbellicæ* (*Itinerary* of Antoninus), from the name of the tribe (Tarbelli) in whose territory it was situated. It appears to have held a high rank among the towns of Novempopulana. In the writings of the English chronicler, Roger de Hoveden, the town is mentioned under the name of *Civitas Akensis*: at a later period the name was corrupted into *Aqs* or *Acqs*, from which, by the addition of the preposition *de*, we have the modern designation *D'Ax* or *Dax*.

After the downfall of the Romans, the town passed into the hands of the Goths and the Franks. From the twelfth century to the year 1451, it was under the English crown. When the English were driven out of Gascogne, Charles VII. united Dax to the French monarchy.

The bishopric of Dax is very antient. It is said to have been founded in the third century by St. Vincent, a martyr, whose body was said to be preserved in a church near the town. Nothing certain is however known respecting the see until A. D. 506, when the bishop, Gratian, assisted at the council of Ayde. The diocese comprehended parts of Béarn and Basse Navarre (Lower Navarre), as well as of the district of Les Landes, in Gascogne. The bishop was a suffragan of the archbishop of Auch. The see is now abolished. Before the Revolution there were several convents in the town and suburbs.

Dax is the chief town of an arrondissement, which comprehends the south-western part of the department: the population of the arrondissement in 1832 was 99,463.

DAY, any astronomical period which depends directly upon the earth's rotation; or the interval between two transits over the meridian of any point in the heavens, real or imaginary. But the only *days* distinguished by that name in astronomy are the *sidereal day*, the *real solar day*, and the *mean solar day*.

The *sidereal day* is the interval between two transits of the same fixed star; that is, the absolute time of revolution of the earth. It is divided into 24 sidereal hours, &c. It begins when the equinox is on the meridian of the place.

The *real solar day* is the interval between two noons or transits of the sun over the meridian. Owing to the unequal motion of the sun, as well as the obliquity of the ecliptic, it is not of the same length at all periods of the year. The *mean solar day* is the average of all the real solar days; it is derived by supposing a fictitious sun to move round the equator, and uniformly in the same time as the real sun moves from an equinox to the same again. The method of adapting the motion of this fictitious body to that of the real sun will be explained in **TIME, EQUATION OF**.

The civil day, in England at least, is the mean solar day, and begins at midnight; that is, when the fictitious sun is on the invisible part of the meridian. But the astronomical day always begins at the noon of the civil day, and the hours are reckoned forward up to 24. Thus eleven o'clock in the morning on the twelfth of January (civil reckoning) is 23 hours of the astronomical *eleventh* of January. Afternoon, and up to midnight, the astronomical and civil reckoning coincide.

The mean solar and sidereal days are thus related: the mean solar day is 24 h. 3 m. 56 s., 55 of sidereal time; and the sidereal day is 23 h. 56 m. 4 s., 09 of a mean solar day.

The antients almost universally began their day at sunrise, with the exception of the Arabians, who began at noon, and the Egyptians at midnight. Among the moderns, most of the eastern nations begin at sunrise, with the exception of the Arabians, who still begin at noon, and the Chinese, who reckon from midnight. The Austrians, Turks, and Italians reckon from sunrise, and other European nations from midnight.

DAY, THOMAS, was born at London in 1748. His father held a place in the Custom House, and died when he was a year old, leaving him a fortune of 1200*l.* a year. He received his school education at the Charter House, and at the age of sixteen was entered a gentleman commoner of Corpus Christi College, Oxford, where he remained for three years, but left without taking a degree. He then spent some summers in travelling through and residing in France and other parts of the continent. He had already adopted certain strong and peculiar opinions on the subject of education, holding, apparently, on the one hand that the

common mode of education was wholly vicious, and on the other, that by a proper education there was scarcely any thing that might not be accomplished. About the year 1769 he proceeded to put his theories to the test of a bold experiment, by selecting from the foundling hospital at Shrewsbury two girls of twelve years of age, with the design of rearing them according to his own notions, and then making one of them his wife; and although this speculation failed in the main point, its eccentric author never having married either of his protégées, both the girls, with the portions he gave them, obtained husbands, and by the propriety of their conduct through life did honour to his training. In 1778 Mr. Day married Miss Milnes, of Yorkshire, a lady similar to himself in her tastes and opinions, and having a fortune as large as his own. The following year he was called to the bar; but he never practised. Meanwhile, in 1773, he had made his first appearance as an author, in conjunction with his friend Mr. Bicknell, in a poem entitled 'The Dying Negro,' a production which is said to have had a considerable share in exciting the public feeling against the atrocities of the slave-trade. In 1776 he published another poem, called 'The Devoted Legions,' being an attack upon the American War. It was followed the next year by another on the same subject, entitled 'The Desolation of America.' After this he published several political pamphlets in prose; namely, in 1784, 'The Letters of Marius; or Reflections upon the Peace, the East India Bill, and the Present Crisis,' and 'A Fragment of a Letter on the Slavery of the Negroes' (in the United States); in 1785, 'A Dialogue between a Justice of Peace and a Farmer;' and in 1788, 'A Letter to Arthur Young, Esq., on the Bill to prevent the Exportation of Wool.' In 1783 appeared the first volume of the work by which he is now principally remembered, his 'History of Sandford and Merton;' the second volume was published in 1786, and the third in 1789. The object of this fiction is to illustrate and recommend the views of the author on education and on human nature generally; and it is a good picture of both his intellectual and his moral character. Its freshness and vigour, and the strain of disinterestedness and philanthropy that pervades it, have a charm, especially for the young; but the narrowness of the writer's views makes it useless for any practical purpose, and nearly equally valueless as a piece of philosophy. He is one of those speculators who look at the wide and varied field of human affairs through an oaten pipe. Day is also the author of another shorter work of fiction, called 'The History of Little Jack.' He was killed 28th September, 1789, by a kick from a young horse, which he was training upon some new principle; for his schemes for the improvement of education embraced the inferior animals as well as his own species. It ought to be added, however, that a spirit of uprightness and disinterestedness, and a scorn of everything mean, marked the conduct not less than they do the writings of this able and good man, but not very profound thinker. (Chalmers, and *Biog. Brit.*)

DEACON, an ecclesiastical term of Greek origin, from *Διάκονος* (*Diákonos*, literally, *a servant*), introduced into the Saxon vocabulary, and continued in use to the present time.

It designates one of the *orders* in the Christian priesthood, the lowest of the three—bishops, priests, and deacons.

The first institution of the order is particularly set forth in the sixth chapter of the Book of Acts. The administration of the charities in the Church of Jerusalem was complained of as partial by the Grecian converts. The apostles, in whom the administration had been vested, thought it expedient to divest themselves of this duty, and to devolve it on other persons, that they might devote themselves to prayer and to the ministry of the word. Seven persons were selected for the office, and by prayer and the imposition of hands ordained deacons.

It appears by the first Epistle of St. Paul to Timothy, that there were deacons in other Christian churches, and probably in all where such an officer was needed. He gives instructions (chap. iii. 8-13) respecting the character which became persons who should be admitted into the office. See also *Phil.* i. 1. There were also deaconesses in the primitive church, one of whom, Phœbe, is mentioned *Rom.* xvi. 1. This female officer may be traced to the eleventh or twelfth century.

The peculiar office of both deacons and deaconesses was to attend to works of mercy, to be the administrators of the alms of the more opulent members of the church.

In the English church the name continues, and the peculiar form of ordination, but the peculiar duties of the office seem to be lost sight of. In fact the Poor Laws, by creating certain civil officers whose duty it is to attend to the necessities, have rendered the services of the deacon in this his characteristic capacity less necessary.

In some dissenting communities there are deacons who still discharge the duties for which the office was instituted, collecting the alms of the people at the sacrament, and distributing them among the poor. But they are always laymen, or persons who have not gone through the forms, generally few and slight, of ordination, as practised among the dissenters.

There is a form for the ordination of deacons in the English church: some clergymen never take priests' orders. It appears by the Rubric that a person in deacon's orders is empowered to read publicly the Scriptures and homilies, to catechise, to preach when licensed to do so by the bishop, and to assist a priest in divine service, and especially in the Communion. When contemplated in the light in which this form places him, he appears as an assistant to a priest, for he is to seek out the sick and poor and report them to the priest, and in the absence of the priest to baptize. This latter permission has led to the introduction of the performance of other ecclesiastical duties, namely, the celebration of matrimony, and the burial of the dead. In fact the deacon performs all the ordinary offices of the Christian priesthood, except consecrating the elements at the administration of the Lord's Supper, and pronouncing the absolution.

A person may be ordained deacon at twenty-three. He may then become a chaplain in a private family; he may be curate to a beneficed clergyman, or lecturer in a parish-church, but he cannot hold any benefice, or take any ecclesiastical promotion. For this it is requisite that he take priest's orders.

DEAD SEA, called also Lake Asphaltites, is situated in the Holy Land, or Palestine, between 31° and 32° N. lat. and 36° and 37° E. long. It extends nearly north and south about 50 miles, and measures about 25 miles where widest, but it narrows considerably towards its extremities. The Arabs call it *Bahr Lot* or *Lud*, and those of them who inhabit the adjacent country sometimes conduct the traveller to a pillar coated with asphaltum, which they pretend is the pillar of salt into which Lot's wife was transformed, according to the account of the sacred volume. The towns of Sodom, Gomorrah, Adama, Seboyn, and Segor, which were swallowed up by its waters, are said to have been on its western bank, where some few ruins occur.

The water of the lake is pungent and bitter. Asphaltum floats on its surface, and covers also the whole of the extent of its shores, and likewise the ruins still existing upon it. The lake throws up on its banks pieces of petrified wood and porous stones in a calcined state. The river Jordan falls into it at its northern extremity, but the lake has no outlet. From its northern extremity a sandy plain extends along the Jordan; but on all other sides it is enclosed with masses of bare stones and rocky hills, on which only small tufts of certain shrubs grow, from which a balsam is extracted. The deep but narrow valleys which traverse these masses of stone are inclosed by high mountains, and the whole presents a dismal and sombre sight. At the most southern extremity begins a stony valley, which traverses Arabia Petræa nearly in a southern direction, and terminates at the gulf of Acaba, the north-eastern arm of the Red Sea. The northern part of this waterless valley is called *El Ghor*, and the southern *El Araba*. On both sides of it extend the high and stony table-lands of Arabia. (Count Forbin's *Travels in Greece, Turkey, and the Holy Land.*)

DEAF AND DUMB. The subject of deafness and its consequences has not received that degree of attention which its importance deserves. Few persons have an idea of the extent to which it prevails, and fewer still form correct notions of the amount of deprivation under which a totally deaf person labours. Till institutions for the instruction of the deaf and dumb began to multiply, and thus to attract public notice and sympathy towards this unfortunate class of persons, it was believed that the deaf and dumb formed a very minute fraction of the population; and a very few years ago one of the highest dignitaries of the Church of England assured a gentleman who applied

to him on behalf of the deaf and dumb in his province, that during his long life he had never heard of more than two persons in this melancholy condition. Perhaps one cause of the general want of knowledge on this subject is the incapability of the deaf and dumb to give utterance to their own deficiencies; the very nature of their deprivation prevents their making it known and obtaining relief: thus generations have lived and died in wretchedness and obscurity.

The most complete tables which have been formed for showing the proportion of deaf persons to the rest of the population are contained in the 'Third Circular of the Royal Institution for Deaf Mutes' at Paris. From this circular the following table is taken, which shows not only the extent, but the universality of the calamity, and the proportion which the deaf bear in different countries to the whole community.

Countries.	No. of Deaf and Dumb.	Proportion to Population.
Portugal	2,407	1 in 1585
Spain	7,255	„ 1585
France	20,189	„ 1585

United States of America	6,000	„ 2000

According to this statement, the general accuracy of which has been repeatedly confirmed in various districts by special returns, the proportion of deaf persons to the population of Europe is 1 to 1537. The United Kingdom contains 12,400, or 1 to 1622 of the population.

Deafness occurs in every degree, in some cases only amounting to an insensibility to very sharp notes. Many people cannot hear the squeaking of the bat and the mouse. By holding the nose, inflating the ears, and ceasing to breathe, the ear is rendered more open to base notes, and more deaf than it naturally is to sharp notes. Dr. Wollaston constructed a small organ, whose notes began where the sharp notes of ordinary instruments end; the notes of his organ increased in sharpness till they became inaudible, though he was certain that it continued to give sound from feeling the vibrations equally with the lower notes. He thus found that some people could hear seven or eight notes higher than others, and that children could generally hear two or three notes higher than grown-up people. In some persons the accuracy of the ear is merely impaired in distinguishing faint sounds, and sounds somewhat similar; instances of this kind are particularly evident in infants, whose first attempts at speech are a very remote similarity to the sounds they hear, and become more perfect as their ear is educated, and in some cases remain imperfect through life, in consequence of defect in the organs of hearing. All imperfections of speech do not arise from imperfect hearing: an indistinct articulation may result from various other causes, from carelessness, from defective organs of speech, or an imperfect formation of those organs, from irregular respiration producing hesitation, and in

some instances proceeding from nervousness. The principles which regulate utterance have been practically considered and acted upon by Mr. Cull, to whose pamphlets on 'Impediments of the Speech,' and on 'Stammering,' reference may be made with satisfaction by those persons whose utterance is defective. The discovery of these principles is however due to Dr. Arnott. Up to the period of the publication of his 'Elements of Physics,' in 1827, scientific and regular practitioners had no cure for stuttering. This work should be consulted by all those persons who wish to ascertain the causes, moral or physical, which tend to produce defective speech.

By total deafness is meant that state in which the organs of hearing are as insensible to sound as any other part of the body. To persons in this condition, sound is a mere vibration which can be felt, but very imperfectly distinguished. Yet persons who are generally considered as totally deaf, are not all equally so. There are cases where the firing of a gun is unheard though immediately near the deaf person, and others where a gun fired at a quarter of a mile distant is heard, and distinguished from the falling of a heavy weight upon a boarded floor. In some instances, the human voice in a great variety of its louder single intonations can be recognized, though the loudest reading or the highest pitch of a speaker would make no impression. Dr. Itard, of the Royal Institution for the Deaf and Dumb, at Paris, considers that more than half of the pupils received into that Institution are of that class who hear the least; about the same proportion would be found in the English Institutions. The other half comprise cases more or less of imperfect deafness, an expression which must by no means be confounded with imperfect hearing. In all these conditions of deafness, the person is consequently *mute*, or *dumb*. Hence the expression *Deaf-Mute*, as used in the continental languages, and *Deaf and Dumb*, as used in England and America, to designate a person so deaf as to be inaccessible by the ordinary means of lingual communication, and unable to make known his thoughts, wishes, and feelings, in our conventional tongues. As articulation can only be acquired by those who hear, it follows that according to the condition of the power of hearing, will be, *ceteris paribus*, the distinctness of articulated sounds. Hence in the instruction of deaf-mutes, it is generally found that those pupils who distinguish the different tones of the human voice most correctly become the best speakers of the artificial pronunciation, which is taught in some of the institutions for the deaf. There are certainly cases where the articulation of a totally deaf person is pleasanter to hear, softer and less monotonous, than in some instances of imperfect deafness, but these depend upon other causes, as the natural tone of the voice, the attention of the pupil, or the care of the instructor.

In cases where deafness is not congenital, but supervenes at a period after articulation has been acquired, at the age for instance of four or five years, the power of speech is gradually lost, the voice becomes monotonous, and unless the practice of speaking is continued, the power of speech is lost almost as completely as though it were a case of original deafness. A case of this kind has come under our notice, in which the patient lost his hearing before he was five years of age. At thirteen years of age, his pronunciation of the words *hat*, *coat*, *book*, was, as if they were written *hat-a*, *coat-a*, *book-a*. His knowledge of things had been kept up entirely by vocal practice, for he knew nothing of written words or writing. A case somewhat analogous to this, is that of a nobleman now living, who was an officer in the battle of Waterloo; his auditory nerve was destroyed by the concussion of the air, from the bursting of a shell, or from the report of a cannon. He is now totally deaf, and has consequently lost all control over his voice, which has become discordant, and difficult to be understood, even by those who are accustomed to associate with him. A similar instance is mentioned by an American writer, 'in which entire deafness, taking place at the age of eighteen, so affected the articulation, that the individual was no longer intelligible, even to his friends.'

The importance of an inquiry into the causes of deafness, induced the directors of the institution at Paris to issue circular letters, containing a series of questions, as follows, addressed to the parents of their pupils.

1. Was the child born deaf, or has he become so since his birth?
2. In the first case, what circumstances preceded, accom-

panied, or followed his birth? In the second case, at what age was he found to be deaf?

3. Since the time of his birth till that when he lost his hearing, has he suffered under any illness, or met with any accident?

4. Is the loss of hearing to be attributed to this illness, or this accident?

5. Independent of deafness, has he any other infirmity?

6. In this case, was this infirmity anterior or posterior to the deafness, and for how long?

7. Had the child spoken before he lost his hearing?

8. How many children are there in the family, and among them how many deaf-mutes?

9. Are the father or mother deaf and dumb, or have they any other disease?

10. What was the age of the father and mother at the time of the child's birth?

11. What is their occupation?

12. Is the residence of the parents in a flat, mountainous, or marshy country? Is it exposed to humidity, or to any other peculiar atmospheric influence?

Lastly, The parents or the friends of the child are requested to give all the particulars which it is possible to furnish explanatory of the causes of deafness.

The following is a brief notice of the result of this inquiry. Out of 102 children whose parents furnished the required information, 52 were born deaf, 37 became so after birth, and of the remaining 13 no positive information could be obtained. Of the 37 who became deaf after their birth, 7 lost their hearing during the first year, 13 in the second, 7 in the third, 1 in the fourth, 5 in the fifth, and 4 in the eighth year of their age. On examining into the causes of the deafness of these children, 8 cases were found to arise from violent convulsions during the period of dentition or from fright; in 10, deafness supervened upon epidemic fevers—cerebral, nervous, scarlatina, inflammatory, putrid or catarrhal; 2 cases followed measles, 6 arose from verminous diseases, 1 from a deposit of matter under the ear, 1 from a violent sore throat, 1 from a fall, 1 from a cold, and 1 from ophthalmia caused by a scrofulous habit; 7 cases of deafness were attributed to virulent diseases, of which the parents could not explain the nature; lastly, four children who were not born deaf lost their hearing without it being possible to refer the loss to any illness of a serious nature. Of these 102 deaf-mutes, 21 belong to families in which there are other children afflicted with the same infirmity; 9 families contain each two deaf and dumb children among two, three, four, five, six, and eight; 7 families have each three deaf-mutes, out of three, four, seven, eight, and twenty-six children; 3 families contain each four, out of four, seven, and ten children; 1 family has five deaf and dumb children out of eight, and there is 1 family which out of ten children contains seven deaf-mutes; with the exception of one brother and one sister who lost their hearing after birth, all these children, belonging to families where there are several deaf mutes, are afflicted with congenital deafness.

Many cases of deafness are attended by circumstances which deserve to be especially recorded. One deaf-mute from birth had a maternal great-grandmother who was afflicted with the same malady; another child, who lost its hearing at the age of four years, is the issue of a father who was also affected with deafness at the age of seven years, and there are several other parents who have laboured under the same infirmity. In the family which numbers 7 deaf-mutes out of ten children, the father had an aunt who was deaf from birth; in another family, which contains 2 deaf-mutes, the sister of the father married with the brother of the mother has five male children, of whom three are afflicted with congenital deafness. In one family the father has been twice married; by his first wife he had two children who can hear; by his second he has one daughter born deaf and dumb. In a second family the father has also contracted two marriages; he had three deaf and dumb children by his first wife, and four children who hear by his second. In the family which contains 3 deaf-mutes out of twenty-six children, the father has been married four times; his last wife, who is affected with goitre, has had five children, three of whom are deprived of hearing. Lastly, in the family which, out of eight children, numbers five deaf and dumb from birth, all the five were born in a damp house, where the persons who had formerly resided had three children, of whom two were deaf and dumb.

We are enabled to compare the above results with the results of an inquiry into a nearly similar number of cases obtained at one of the English institutions, the Yorkshire Institution for the Deaf and Dumb. The details in the latter case are upon 110 pupils, and while they, in many respects, verify and corroborate the evidence already before us, in some important particulars there is considerable variance. It appears that all ordinary means are used to obtain correct statistical data at the Yorkshire Institution, not only on the physical influences which cause deafness, but also on the effects of moral and intellectual culture. A sufficient number of years has not yet elapsed since the institution was established to enable us to draw any important inferences from the facts hitherto recorded. From November, 1829, to August, 1835, 110 pupils were received into the Yorkshire Institution: of this number 75 were born deaf, 26 became so after birth, and of the remaining 9 no accurate information could be obtained. The statements as to the time at which deafness was first perceived in the 26 above mentioned are very vague, but it is certain that a very large majority became so under the age of three years, and that only one occurred at five years of age. Respecting the diseases on which deafness followed, the information is full and complete, so far as the observation of parents and the attestation of the medical practitioners of the various families could make it. In 9 cases the deafness is reported to have arisen from hydrocephalus and other affections of the brain, as inflammation, brain-fever, &c.: in 5 from general fever, scarlet-fever, &c.; in 4 from measles; in 3 from convulsions and other fits; in 2 from inflammation of the lungs; in 1 from cold; and in 3 cases from diseases which were unknown, or on which the friends of the children had no positive knowledge. Seventy-four of the 110 cases are in families where there are only these single instances of deafness, the remaining 36 belong to 27 families, and these 27 families contain 68 cases of deaf and dumb offspring. Seventeen of them have each 2 deaf and dumb; seven have each 3; two have each 4; and one has 5, making in all 68. Of these 27 families

27				68		161

This statement presents us with 27 families containing 161 children, of whom 68 are deaf and dumb. It has been mentioned that 26 of the 110 cases now under consideration are the effects of accident or disease; 24 of these instances may be somewhat positively concluded to be in families free from congenital deafness, from the fact that these are the only instances known in the families. The other case of two children, making the 26, is that of a brother and sister who are said to have become deaf after birth, in each case from inflammation of the lungs at two and a half years of age; it is proper to remark that in this instance both the father and the mother of the two children died of consumption at an early age, and that both the children are subject to pulmonary complaints and other affections indicative of disease.

Out of the total number of children that have been received into the Yorkshire Institution 8 were subject to goitre; 7 to other scorbutic tendencies; 5 to fits; 2 to partial paralysis; 2 to consumption, and 8 were of otherwise delicate constitutions; three have died, 1 of inflammation of the lungs, one of dropsy supervening on scarlatina, and one of a very gradual consumption. In five families idiocy exists; in several, goitre is found in the parents; in 19, one or both the parents died early, or before middle age; in several, deafness exists in collateral branches of the family; in one case, where the father is deaf and dumb, he has two children who can hear, and one who is deaf and dumb. In another, the family consists of four children, two of whom

are deaf and dumb, and twins. The number of families employed in agriculture in the district to which the operations of the institution extend is 62,377; employed in trade and manufactures 140,856; other families 73,333. Of the 110 pupils 63 were from mining and manufacturing districts, and chiefly from large towns, and 47 were from agricultural districts. Of these 110 pupils 20 were found to be of decidedly superior intellectual powers; 61 were of ordinary talents; 19 were inferior in mental endowments, and 10 were very low in intellect—compared even with those of the next grade, but not so low as to be considered idiots, for even these were able to connect simple ideas in writing, to comprehend all ordinary subjects connected with their daily exercises and wants, and were capable of moral improvement. In each of these *ten* instances it is remarkable that causes exist which partly account for this intellectual barrenness; in one instance the child and both the parents are unhealthy; in another there exists paralysis of one entire side of the body, and doubtless of one side of the brain, as the child is of a very active temperament; in the next case, there is a general feebleness of the constitution (in this case both the parents are healthy, and a very large family of children are remarkably so); in two instances the children are subject to fits, in another case the child is a species of dwarf, being physically and mentally undeveloped, remarkably good humoured, and the moral sense good, considering the unfavourable circumstances under which the child was brought up; in the ninth instance the pupil laboured under St. Vitus's dance, and scorbutic affections; and in the tenth, the mother has goitre, the father is dwarfish, and one of the brothers is an idiot.

Such are some of the results which have been obtained at one institution, and we now submit the form in which the information is recorded. This form embodies particulars which, from the comparatively short existence of the institution, cannot yet be completed, and it is probably capable of improvements which in due course will present themselves. At the same time it is a document which, as far as it goes, is satisfactory, and which even in its present form may serve as a model till something better is suggested. The book in which the details are kept is divided into columns varying in width according to the information to be written in them. The heads are as follows:—No. of Case, Name of Child, Description and Circumstances of Parents, Moral and Physical Habits of Parents and Family, Residence, Physical Character of the District, No. of Family, No. of Deaf and Dumb, Age of Pupil, When Admitted, Born Deaf or became so, and when, Under what Circumstances became Deaf, If otherwise Diseased and its Nature, No. of Years at School, Intellectual Character, Moral Character, Why left School, Deafness in Family, Cases of Consanguinity existing between Parents before Marriage, Business on leaving School, Additional Remarks.

The only statistical document which the publications of the London Asylum for Indigent Deaf and Dumb Children furnish is the following very important one, extracted from their Report for June, 1833, by which it is shown that 20 families, containing 159 children, number 90 deaf-mutes.

Names.	Parents' Description.	No. of Children.	No. of D. & D.
Mary Martin	Father a labourer	10	7
James Wm. Kelly	do. a porter	8	7
Mary Aldum	do. a broadcloth weaver	12	6
William Coleman	Mother a widow	11	5
David Thompson	Father a smith	10	5
James Cousens	do. a brickl's labourer	8	5
George Franklin	Mother a widow	8	5
Silas Vokius	Father a labourer	7	5
Thomas Barnes	do. a cobbler	6	5
Thomas Pounceby	do. a dyer	12	4
Henry Tatler	do. a working jeweller	10	4
Abram. Murgatroyd	do. a cloth weaver	9	4
William Baynes	do. a schoolmaster	8	4
Mary Lovegrove	do. a labourer	8	4
Elizabeth Cherry	do. a watch-finisher	7	4
William Cockton	Mother a widow	6	4
Robert Mortimer	Father a cloth weaver	7	3
Francis Hancock	do. a small farmer	6	3
Susannah Rye	Mother a widow	3	all 3
Eliza Fox	(An orphan)	3	all 3
		159	90

From a circular issued by the National Institution for the Deaf and Dumb of Ireland, we are enabled to extract some interesting statistical details which other institutions do not supply; they are stated as follows:—'We have kept an accurate registry as to all the circumstances of 489. These belonged to families in which there were 2020 chil-

dren, of whom 563 were deaf and dumb. Of the above 489 applicants, 279 were boys, and 210 girls: 423 were born so, and 66 became deaf after birth, from various diseases and accidents, such as falls, blows, kicks of animals, colds, measles, fevers, worm-fevers, abscesses, palsy, &c. Ninety-seven were not wholly deaf, though so much so as to be quite incapable of learning in the common way; and all those born deaf, as well as almost every one of such as had lost their hearing in early childhood, as a consequence of surdity, were totally dumb. The following scale will show the number of cases of deaf-mutes in different families of from 1 to 12 children:—

Total Number of Children in the Family.	Number of these Children Deaf and Dumb.				
	1	2	3	4	5
1	39				
2	39	6			
3	70	8	1		
4	53	8	2		
5	61	14	8		
6	45	4	3		
7	30	7	7	1	1
8	17	7	1		
9	5		1	1	
10	4	1			
11	1				
12	1				

Number of Families in which these proportions occurred.

'In one case twins were born deaf and dumb. Several had minor defects of sight in one or both eyes. Four (3 in one family) could not see during sun light; 3 had lost 1 eye, and 5 were blind of both; about a dozen had epileptic fits; very many were afflicted by scrofula (king's evil); and about 12 or 13 have been since ascertained to be more or less idiotic. To show the poverty of the families the following classification is sufficient:—in 115 cases the parents were labourers; in 79, small farmers; in 32, servants; in 28, weavers; (in 13 unknown;) in 11, shoemakers, blacksmiths; in 10, tailors, soldiers; in 9, carpenters; in 8, petty grocers; (7 were foundlings;) in 6, washerwomen; in 4, beggars, clerks, fishermen, masons, pensioners, policemen, seamen, shopkeepers, tradesmen; in 3, bakers, carriers, house-painters, schoolmasters, tide-waiters, woollen-drapers; in 2, butchers, confectioners, gardeners, innkeepers, hackney-coachmen, hucksters, millers, publicans; in 1, bleacher, brass-founder, broker, brogue-maker, cap-maker, Chandler, chimney-sweeper, constable, cooper, cork-cutter, corn-merchant, currier, cordwainer, dairyman, dancing-master, dyer, flax-dresser, game-keeper, harness-maker, mate, millwright, navy-officer, oyster-seller, pedlar, plasterer, postman, postmaster, sawyer, spinner, surveyor. Of these almost exactly one-half were residents in towns, and one-half in country places.'

The 'Thirteenth Report of the American Asylum at Hartford,' contains many interesting particulars on the statistics of deafness. Since the commencement of that institution in 1819 to 1829, 279 pupils had been received, 157 males, and 122 females. 'Of these, 116 were born deaf, and 135 lost their hearing in infancy or childhood, by disease or accident; with regard to 28, it is uncertain, or doubtful, in what way this misfortune befel them. It appears from this that a somewhat greater proportion have become deaf, and consequently dumb, by some adventitious cause after their birth, than by any constitutional defect. So far as accurate information has been obtained among those who have become deaf by disease or accident, 15 became so quite in infancy; 27 before 1 year of age, 58 between the ages of 1 and 4 years; 14 between 4 and 5 years, and 9 between 5 and 7 years of age. Among the causes producing this calamity, 25 cases are attributed to the scarlet fever, 16 to various kinds of fever not defined, 7 to the canker-rash, 5 to the measles, 2 to an inflammation of the brain, 1 to the small-pox, 1 to the whooping-cough, 1 to palsy, 1 to the discharge of cannon at a military review, and 1 to sudden falls. In very many cases it has been found impossible to procure satisfactory information. The 279 pupils have come from 247 families, 47 of which have contained more than 1 deaf and dumb child; 20 families have each contained two; 4 families, three; 7, four; 4, five; 2, six; and

, seven. In one family the father is deaf and dumb, and also four of the children. In another, the father and two children are deaf and dumb. These are the only instances in which either of the parents of the pupils has laboured under this defect, while in several other cases which have come to our knowledge, one or both of the parents have been deaf and dumb, yet their children have heard perfectly well; so that it does not appear that the malady is always an hereditary one. It seems rather to be found among certain families and their collateral branches. Thus two of the pupils (sisters) have had fourteen kinsfolks deaf and dumb, the whole sixteen being descended from the same great-grandmother; while what renders this fact the more singular is, that their common ancestress, all her children, and all her grand-children, possessed the faculties of hearing and speech.'

In Bébien's '*Journal de l'Instruction des Sourds-Muets*,' No. ii., p. 117, 118, it is remarked that the canton of Vaud, in Switzerland, containing 122 parishes, presents a remarkable phenomenon. In 67 parishes there is not a single deaf-mute; in the other 55, there are 152, which is about one in every hundred of the population. In the district of Moudon there are 43 deaf-mutes among 6602 inhabitants; in Payerne only 25 in 6095; in Eaubonne 20 in 9688; and in Vallée, 12 in 3938. The physical causes of this difference are unknown, but of 152 deaf-mutes 66 were found capable of instruction. Most of the other 70 are also afflicted with cretinism; age and diseases of various kinds unfit the others for instruction. Almost all are the children of poor parents, who could not contribute to the expenses of education.

On the origin and transmission of peculiarities, whether resulting from conformation or from disease, there is a large assemblage of facts in the writings of Blumenbach, Lawrence, Esquirol, Gall, Spurzheim, the Combes, and others; sufficient perhaps to enable the inquirer to come to some general conclusions, and to point towards laws which influence the physical condition of man. The more the inquiry descends into detail, the greater are the difficulties which attend it. The physical history of deafness is an almost unexplored field for research. Of late years, the writings of Deleau and Itard have made known some facts calculated to assist in the diffusion of correct views on this malady, and their experience has led to some results favourable to the sufferers; but at the same time it is highly desirable that facts should be collected wherever they can be obtained, as these alone can lead to the formation of correct opinions and the suggestion of remedial measures. The bad effects of in-breeding are known to all who are engaged in the rearing of horses and other animals; it has also produced some melancholy instances in the human race. To these it may be added that many cases of deaf-mutes known to the writer of this article, are the offspring of first-cousins and of other marriages of near consanguinity. Should the offspring of such marriages be frequently found to labour under physical defects, may we not safely infer that a natural law is transgressed, and that it is followed by its peculiar punishment? We conclude this portion of our subject with a powerful conviction that public institutions should unite their efforts for the common improvement of society; that they should obtain every information directly or indirectly bearing upon those cases which come under their observation; and from time to time bring their details into one general form. Connected with a system of registration, very ample details might be obtained. In the operation of such a system every case of physical defect observed at the birth of a child, or soon after, should be recorded; and at stated periods the heads of families should report on any deficiencies to which their children have become subject, whether arising from an original but previously unnoticed infirmity, or derived from accident or disease. Thus all cases of physical defect, whether organic or functional, all instances of mental imbecility, would be accumulated, and such a body of facts would prove in no small degree useful to society.

Before the practicability of instructing the deaf was known, it was generally supposed that instruction by means of language was limited to those who could hear. The idea never occurred, or if it did, was as instantly rejected, that the deaf man was not, by reason of his deafness, excluded from the means of acquiring knowledge. It was not till the sixteenth century that the possibility of carrying forward the process of education in the absence of

all hearing, received any serious consideration. Even at the present day there are many persons who are at a loss to conceive not only how abstract notions, but even how the names of palpable objects are made known to the deaf, and at a still greater loss to imagine how they can be brought to use language to express their ideas. Having themselves obtained knowledge through the ear, having been accustomed to impart their thoughts by oral communications, they seem to forget that the mind has intelligence in all the senses, connecting it with the external world, and conveying knowledge to those higher faculties which compare, discriminate, and judge. In an intelligent though uneducated deaf person, an observer would find these processes going forward, though confined indeed to a very limited sphere, owing to the poverty of his knowledge, but still knowledge, and deduced from observation. The existence of the reasoning power being thus evident, the means to cultivate it would be the next object for philosophic investigation. That Aristotle had never made these observations and investigations is evident, or he would not have come to that absolute conclusion which excludes the deaf from all participation in knowledge. Among other people of ancient times these unfortunate beings were the objects of a species of proscription, being supposed to labour under the curse of Heaven. Previous to the time of Justinian the Roman laws maintain an absolute silence upon the deaf and dumb. They speak frequently of deaf persons, not being dumb; and also of dumb persons, not being deaf; but never of those labouring under both these deprivations. The Code (lib. vi., tit. xxii. l. 10) mentions the deaf and dumb in a manner express and special. Five classes of persons labouring under one or both of these deprivations are established. Those who from their birth were deaf and dumb were legally incapable of making a will, or of manumitting a slave, and laboured under other civil disabilities.

The reader will find in the work of C. Guyot, of Groningen, which is a dissertation written in Latin on the legislation relative to the deaf and dumb down to 1824, with a list of authors, all that relates to this part of the subject. Saint Augustine declares that the deaf and dumb are shut out from obtaining religious knowledge; and many respectable ecclesiastics in the time of the Abbé de l'Épée openly condemned his undertaking. The benevolent abbé also informs us that parents considered it a discredit to have deaf and dumb children, and they believed that they fulfilled every claim such offspring could have on them by merely supplying their animal wants, concealing them from the eyes of the world within the walls of a cloister, or in some other obscure abode. He also asserts that in some uncivilized countries the deaf and dumb were in *his* time regarded as monsters, and were put to death as soon as their calamity was ascertained. So that we find naturalists, legislators, divines, philosophers, and even parents, agreeing in the impracticability of conveying knowledge otherwise than by speech, and thereby excluding the deaf and dumb from all means of intellectual improvement.

From the advantages which instruction has afforded to a certain proportion of the deaf and dumb for the last half century, a tolerably correct estimate may be formed of their capabilities for improvement. The deaf-mute living in society, but without instruction, must be regarded as one of the most solitary and melancholy of beings. He is shut out from all but the most imperfect intercourse with his species; and the very intellect by the possession of which he is raised above the lower creation serves only to heighten his calamity, and to render the sense of his deprivation more acute. His perceptions of external objects are indeed accurate but superficial, and confined to a very small sphere. Of the various arts by which the necessities and conveniences of civilized life are produced, he can have no knowledge beyond that which is included in the range of his own vision. Animal desires he feels, and he is led by the conventional usages of society to the performance of moral duties and the avoidance of open and flagrant crime. Thus he becomes experienced as other human beings are in what is right or wrong. He sees that virtuous actions have a certain amount of reward, in the opinions of good men; for he learns to discriminate between those whose actions are proper and those who do wrong; and again, he sees that in many cases vice meets with disapprobation and punishment among mankind. How this kind of experience shall affect his own conduct must depend not only on the circumstances in which he is placed, as to example

and the moral influence of those with whom he has to associate, but also on his own natural tendencies.

The performance of moral duties implies the exercise of intellectual faculties; and from his birth the deaf-mute makes use of his reasoning powers. He is subject to changes of purpose, to changes of feeling, to the passions, the pleasures, and the infirmities common to his species. He is sensible of kindness; he gives proofs of affection. That such is the uneducated state of the deaf and dumb might be proved by the observations of their parents, friends, and instructors in hundreds of instances. That such must necessarily be the case, supposing them not to be idiots, it would be easy to show. We affirm, in contradiction to those who contend that deaf-mutes are naturally more debased than other men in intellect and in morals, that there is not an individual deaf-mute now under instruction—improving, and thereby evincing rational faculties—who, previous to instruction, however disadvantageous the circumstances which attended his earlier years, did not evince moral sentiments and intellectual operations. We have traced the history of many of this class in different ranks of society down to the period when the deprivation under which they have laboured was first ascertained; and we have found invariably that mixture of good and evil in their actions and tendencies which is seen amongst other children. We have also had sufficient proofs of the exercise of intellect even while they were in a state of childhood. The parents of deaf and dumb children can sufficiently attest the truth of these observations.

At the same time, it must be acknowledged that the deaf and dumb are generally inferior in their moral and intellectual powers to those who do not labour under the same defect. But this inferiority is only one of degree, and may be satisfactorily accounted for, in accordance with the opinions above expressed. Andral has described the state of an uneducated deaf and dumb person; and to a certain extent we can adopt his sentiments. Experience and observation among this class of persons would have induced this accomplished pathologist to have bestowed on them even a more liberal endowment. 'The deaf-mute exhibits in his intellect, in his character, and in the development of his passions, certain modifications which depend on his state of isolation in the midst of society. We find him remain habitually in a sort of half-childishness, and he has great credulity: to balance this he is like the savage, exempt from many of the prejudices which we owe to our social education. In him the tender sentiments are not very deep; he appears not to be susceptible either of lasting attachments or of lively gratitude; pity touches him but feebly; he is an entire stranger to emulation; he has few enjoyments and few desires; and the impressions of sadness but slightly affect him. This is what is most commonly observed in deaf-mutes; but this picture is not universally applicable. Some, more happily endowed, are remarkable for the great development of their intellectual and moral nature; there are others, on the contrary, who continue in a state of complete idiocy.' (*Dictionnaire de Médecine*, article *Surdi-Mutité*.) This last remark of Andral's requires some qualification. Deaf and dumb persons who possess intellectual faculties are no more liable to become idiots than others whose organs perform their appointed functions. Their powers may remain undeveloped; they may be ignorant of every thing which depends on intercourse with mankind; their reasonings may be inconclusive, and their inferences erroneous from their confined observations; but still their mental powers will be called into action, and they will be, to a great extent, under the control of their reasoning faculties. This is not the case with idiots: in them there is a total want of self-government, a total absence of intellectual control. There are, at the same time, numerous cases of idiots who are dumb; not, however, in consequence of deafness, but from their incapacity to understand the meaning of language, to imitate it, and to apply it. These persons cannot be classed with the deaf and dumb. It may be this class to which Andral particularly alludes in the latter part of our quotation; for he qualifies his remark in some measure by adding, 'The difference in the intellectual and moral nature of man is often primitive, and independent of all external influences.'

Of the same opinion with ourselves we find Degérando, Bébien (the successor of Sicard), Piroux of Nancy, and all the more successful teachers of the deaf and dumb of the

present day in this country, and throughout Europe and America. The empiricism and deceptions which dishonoured the earlier schools for the deaf are gone. The credulity and the delusions of which these were the effect are no longer a disgrace to our institutions. The craft is no longer confined to a few individuals, for whose benefit it is necessary that mankind should be ignorant of the nature and capabilities of those who are deaf and dumb. To corroborate the views we have taken, the deaf may be allowed to speak for themselves. The beautiful account of the early life of Jean Massieu, which was written by himself for the author of '*La Corbeille des Fleurs*,' exhibits the intellectual and moral condition of Massieu, prior to the education which he received from Sicard. Many passages in that account will abundantly illustrate what we have advanced. Massieu is a metaphysician of no common cast, as will be seen from the following answers to questions proposed to him, by various persons, at different times and places. He was asked, 'What is gratitude?' 'Gratitude is the memory of the heart.' 'What is a sense?' 'A sense is an idea-carrier.' 'What is the difference between things physical and moral?' 'Things physical are the objects which fall under our senses; things moral are manners and actions of mankind, the operations and qualities of the soul. Things physical are material; things moral are immaterial.' 'What is ambition?' 'Ambition is the immoderate desire of governing, gaining riches, or possessing anything which we have not. Ambition is also an excessive ardour for honour, glory, places of distinction, exaltation. It is the movement of a soul which hovers round an object which it is coveting or ardently pursuing.' 'What is hope?' 'Hope is the flower of happiness.' 'What is eternity?' 'A day without a yesterday or to-morrow—a line that has no end.' 'Does God reason?' 'Man reasons, because he doubts, he deliberates, he decides. God is omniscient; he never doubts: therefore he never reasons.' The account of Massieu's early life is printed at the end of Sicard's '*Théorie des Signes*.' Several translations of it have been published.

The first mention we meet with of the capacity of those born deaf to receive instruction, is in the writings of Rodolphus Agricola (born A. D. 1442) of Groningen. He does not inform us who was the parent of the art; but he mentions in his posthumous work, '*De Inventionem Dialecticæ*,' that he had himself witnessed a person deaf from infancy, and consequently dumb, who had learned to understand writing, and, as if possessed of speech, was able to note down his whole thoughts. The truth of this relation was doubted by Louis Vives, of Valentia, who wrote in the beginning of the sixteenth century; but there is as good reason to put trust in Agricola's account as to join in Vives's disbelief. (See the treatise, *De Anima*, of Vives, L. ii. c. *De Discendi Ratione*.) Not long after the death of Agricola, and during the life of Vives, the theoretical principles on which the art rests were discovered and promulgated by the learned Jerome Cardan, of the University of Pavia, his native place. He was born in 1501 and died in 1576. Cardan thus expresses himself:—'Writing is associated with speech, and speech with thought; but written characters and ideas may be connected together without the intervention of sounds, as in hieroglyphic characters.' (See *Journal of Education*, No. VI. p. 204.) The first practitioner of the art of instructing the deaf was Pedro de Ponce: this fact is authenticated by two of his contemporaries, Franciscus Vallesius and Ambrosius Morales. Ponce was a monk of the order of St. Benedict, at Oña. Morales, in his '*Antiquities of Spain*,' thus speaks of Ponce:—'He has already instructed two brothers and a sister of the constable, and he is now occupied in instructing the son of the governor of Aragon, deaf and dumb from his birth, as the others were. What is most surprising in his art is, that his pupils speak, write, and reason very well. I have from one of them, Don Pedro de Velasco, brother of the constable, a written paper, in which he tells me that it is Father Ponce to whom he is indebted for his knowledge of speech.'

The register of deaths of the monastery of the Benedictines of San Salvador de Oña, informs us of the death of Pedro de Ponce, in August, 1584: it records of him that he 'was distinguished by his eminent virtues, and that he obtained a just celebrity throughout the world in instructing deaf-mutes to speak.' John Paul Bonet, also a Spaniard,

published a work on this subject nearly forty years after the death of Ponce. He had probably heard of the success which had been attained in this infant art; and from tradition he might have gained some glimpses into the methods Ponce had pursued; but it appears that he was unacquainted with those methods in any serviceable form, as he represents himself as the inventor of the modes which he pursued, including mimic signs, writing, dactylology, and the oral alphabet. His work, which was in after-years useful to de l'Épée, is entitled *Reduccion de las Lettras, y Arte para enseñar á hablar los Mudos*. [BONET.] During the time of Bonet, the art was also making some progress in Italy. Several individuals are mentioned in Degérando's work who were more or less engaged upon the subject. Affinate wrote at the commencement of the seventeenth century on a manner of teaching the deaf to speak; and Fabrizio d'Acquapendente wrote upon the phenomena of vision, voice, and hearing; and on speech and its instruments. In 1616, Jean Bonifacio published a treatise on the language of action. Pierre de Castro, who was chief physician to the duke of Mantua, instructed the son of Prince Thomas of Savoy, but it is not known on what principles. Pierre de Castro died in 1663. About 1670, Father Lana-Terzi, a Jesuit of Brescia, who is described as 'an ardent investigator of nature,' employed himself on the subject of giving language to the deaf, and teaching the blind to read and write.

Many first discoveries were probably made of this art: several of them originated with, or were carried forwards by, philologists, and particularly among the schemers for an universal language. In England, John Bulwer's name must stand prior to that of any other individual as an author on the subject, and his views, as given in 'Philocophus,' are sound and practical. It has often been attempted to place Dr. Wallis at the head of this list of discoverers in England; but Bulwer's 'Philocophus, or the Deafe and Dumbe Man's Friend,' was published several years before Wallis attempted even his treatise on speech, and he did not publish his claims as an instructor of the deaf till 1670. We find on consulting the above-named work of Bulwer's, that Chap. XV. contains the relation of Sir Kenelm Digby as to what Bonet had accomplished in Spain; and there is no doubt but Wallis obtained information from the same source, as he was in constant correspondence with Sir K. Digby. [BULWER.]

A degree of credit is certainly due to Dr. Wallis for the pains he took to systematize what had been done up to this period, and to bring the philosophy of language to bear upon the art. His two great objects, as stated in a letter to Mr. Boyle, were 'to teach a person who cannot hear to pronounce the sound of words,' and to teach him 'to understand a language and know the signification of those words whether spoken or written, whereby he may both express his own sense and understand the thoughts of others.' Writing, reading on the lips, and speech, the manual alphabet, logical induction, the natural signs—acquired from the deaf—were the means he made use of. From the accounts which have come to us, he succeeded in his purpose. His pupil, Daniel Whalley, was exhibited before the Royal Society in the year 1662. The priority of his invention was disputed by Dr. William Holder, rector of Bletchington, who asserted that he had, in the first instance, taught Popham, one of Dr. Wallis's pupils, to speak. Holder published his *Elements of Speech, with an Appendix, concerning persons Deaf and Dumb*, in 1669, which was some years after Wallis's first writings and practice had been made known.

In the same year in which Wallis made known his inventions for the deaf, 1670, George Sibscota published a little work on the subject, entitled the 'Deaf and Dumb Man's Discourse.' He had learned from the writings of Franciscus Vallesius to what extent Ponce had succeeded. Very little can be gleaned from this work, which consists chiefly of reasoning and theory.

The next author on the subject whose work we shall notice is George Dalgarno. His treatise, though full of the conceits of learning, is essentially practical, and even at the present day it might serve as a guide to an intelligent person who desired to become an instructor of the deaf. The date of this little work is 1680. [DALGARNO.]

Dalgarno announces on the title-page of 'Didascalocophus,' that his treatise is the first (for aught he knows) that has been written on the subject. He commences by showing

that a deaf man is as capable of understanding and expressing a language as a blind man, inasmuch as that all information is conveyed to the mind through the bodily organs. He goes too far however in attempting to show that the deaf man has even superior advantages in acquiring languages to those of the blind. Dalgarno's alphabet is exhibited in the article DACTYLOLOGY.

We will now trace the earlier progress of the art in Holland. Peter Montans offered some remarks on the instruction of the deaf so early as 1635. F. M. Van Helmont published in 1667 a small tract, entitled *Alphabetum Naturæ*, in which he shows how the deaf may be made to understand the motions of the organs of speech, much after the manner of others who are taught to read. His book is remarkable for some singular opinions on the nature and origin of language; and he mentions instances of the result of his system, too improbable to be received even by the most credulous. In 1690, John Conrad Amman, a Swiss physician, residing at Haarlem, undertook the instruction of a girl, deaf and dumb from birth. He seems not to have been aware how much had been accomplished in this art: his own success was decisive; and while his work was in the press, he became acquainted with the writings of Wallis, and entered into correspondence with him. His essay, entitled 'Surdus Loquens,' the speaking deaf man, was published in Latin. His methods were founded on articulation. Amman requires that his pupils' organs of speech shall be rightly formed, then, he says, 'my first care is to make him to sound forth a voice, without which almost all labour is lost; but that one point, whereby deaf persons do discern a voice from a mute breath, is a great mystery of art, and if I may have leave to say so, it is the hearing of deaf persons, or at least equivalent thereto; viz., that trembling motion and titillation which they perceive in their own throat whilst they, of their own accord, do give forth a voice. That the deaf may know that I open my mouth to emit a voice, not simply to yawn, or to draw forth a mute breath, I put their hand to my throat, that they may be made sensible of that tremulous motion when I utter my voice; then I put the same hand of theirs to their own throat, and command them to imitate me; nor am I discouraged if, at the beginning, their voice is hard and difficult, for in time it becomes more and more polite.'

Amman goes on to explain how he communicates the pronunciation of letters singly and combined, in a way sufficiently plain for any intelligent person to follow his plan. He concludes by saying, 'if there occurs to anybody anything either too hard or not sufficiently explained, he may expect a more full edition; or else let him repair to the author, who, according to the lights granted to him, will refuse nothing to any man.'

At the commencement of the eighteenth century the art began to attract the notice of the learned of Germany. Very early in the eighteenth century, Kerger commenced the work of instruction at Liegnitz, in Silesia. His sister was associated with him in his labour. He used drawing, pantomime, articulation, and writing; it is uncertain whether he employed dactylology, but he speaks highly of mimic language. Contemporary with Kerger was George Raphel, pastor and superintendent of the church of St. Nicholas at Luneburg, who had six children, and among them three daughters who were deaf and dumb. Paternal affection made him an instructor of the deaf; he succeeded beyond his hopes, and wrote an account of his proceedings for the benefit of others. His work was published at Lunenburg in 1718. Other teachers in Germany were Otho Benjamin Lasius, the pastor Arnoldi, and Samuel Heinicke. Lasius confined himself almost solely to the teaching of visible language, as reading and writing, associating the forms of the words with the ideas they were intended to convey. It is said that his pupil made a satisfactory progress, and that at the end of two years she could answer important questions on religious subjects. Arnoldi used the means more commonly employed; articulation, drawing, dactylology, writing, and natural signs. Heinicke was the instructor at Leipzig of an institution founded in 1778. He had announced previously to this time that in the course of six weeks he had taught a deaf and dumb person to answer whatever questions were proposed to him. He used those means which had been employed by previous instructors, and he also placed instruments in the mouths of his pupils to regulate the positions of the vocal organs in emitting sounds. He claimed the honour of in-

vention on many points, and guarded with strict secrecy some of his proceedings. He was a man of great self-conceit, irritable, rude, and overbearing. He had adopted the philosophic system of Kant, and published some writings relating to it. He is said to have been a man of considerable talent in the instruction of the deaf and dumb, and of an active and indefatigable spirit. In his controversy with the Abbé de l'Epée, he certainly gained little credit either as a teacher of the deaf, or as a philosopher.

France commenced this art later than the other enlightened nations of Europe. Indeed she opposed its progress by those philosophic prejudices which in other countries had been refuted by actual experience. A deaf-mute from birth, named Guibal, had made his will *in writing* so early as 1679; and proofs of his knowledge and intelligence were produced in court, so that it was confirmed. It is unknown who had been his instructor. About the middle of the seventeenth century, several individuals in different parts of France turned their attention to the subject. Those of whom we know most are Father Vanin, a priest of the Christian doctrine, Rodrigue Péreire, a Portuguese, Ernaud, the Abbé Deschamps, and the Abbé de l'Epée. Father Vanin employed design both for giving information on sensible objects, and also in an allegorical way to illustrate abstract and intellectual ideas. Very crude and erroneous notions must have resulted from a system so imperfect, and so little capable of extensive application. The first person who excited general attention in Paris was Péreire; he obtained the approbation of the Academy of Sciences, to the members of which learned body he exhibited the progress of his pupils. His processes were made a secret even to the members of his family; he however offered to disclose them for a suitable consideration, which was withheld, and the nature of his system is only imperfectly known at the present day. His pupils were highly instructed, more highly perhaps than any of an earlier or a subsequent period. A judgment may be formed of the efficacy of his methods from the report of a committee of the Academy of Sciences, where it is stated that his pupils were able to understand what was said to them, whether by signs or by writing, and that they replied *viva voce*, or by writing; they could read and pronounce distinctly all sorts of French expressions; they gave very sensible replies to all questions proposed to them; they understood grammar and its applications; they knew the rules of arithmetic, and performed exercises in geography; and it appeared that M. Péreire had given them, with speech, the faculty of acquiring abstract ideas. The two best known of Péreire's numerous pupils were Saboreux de Fontenai, and D'Azy d'Etavigny. The former of these two has written an account of the means pursued by his teacher, for which we must refer to the work of the baron Degérando before mentioned. It appears that Péreire employed articulation, reading from the lips, the manual alphabet, and a method of syllabic dactylology. By this latter instrument of instruction he was enabled to communicate very rapidly with his pupils, and by the frequent use of words in different combinations a knowledge of their value was imparted to them. Thus the frequent recurrence of words, through so rapid a mode of intercourse, assimilated the acquisition of language to the ordinary process with hearing and speaking persons. The channel of communication being established, and a copious knowledge of words acquired, the art of the instructor would be little more difficult than that of ordinary education. A few years after Péreire's methods had received the approbation of the Academy of Sciences, Ernaud presented to them a memoir on what he had attempted for the deaf and dumb. The Society gave him encouragement, but it appears that the pupil brought under their notice was not far advanced in instruction. Ernaud's attempts were more particularly directed to measures of physical relief; he revived the sense of hearing in some cases where it had been partially lost, and he asserts that he had never met with an instance of total deafness. Articulation was the principal means he employed. In 1779 the Abbé Deschamps published his 'Cours Élémentaire d'Education des Sourds-Muets.' To the education of this class of persons he devoted his life and his fortune. He followed in the track of Amman, giving the preference to articulation, and the alphabet upon the lips, over the methodical signs of the Abbé de l'Epée. His establishment was at Orleans, where he received paying pupils, and instructed the indigent gratuitously.

In tracing these early steps in the instruction of the deaf

and dumb, we have attended more particularly to the working parts of the different methods by which such instruction was intended to be conveyed. We have passed over the various philosophic theories with which some of these methods are encumbered, because they are either forgotten, or rendered obsolete by recent discovery. Much learning was antiently wasted on subjects in themselves trivial, mysterious, or incomprehensible; yet to such researches we owe much valuable knowledge. It seems that no investigation into the laws of nature, however absurd or unattainable the immediate object of such investigation, is utterly without reward. The alchemists of olden times, though failing to discover the wonderful stone for which they sought, found out new properties, new substances, and new combinations, which cheered their labours and conferred direct benefits on society. So, with many of the writers we have noticed, their speculations, though wild, have not been in vain; the useful parts of their systems have been retained, and are now diffusing good among the class for whom they laboured.

The Abbé de l'Epée was one of the most active and benevolent labourers in this task of humanity. He brought into systematic operation the notions which had previously prevailed on the possibility of conveying intellectual knowledge to deaf-mutes, and added to these stores of experience from the resources of his own highly-gifted and well-disciplined mind. He certainly succeeded to a greater extent than any of his predecessors in enlisting the public feeling in his favour, and in drawing the attention of sovereigns to one of the most unquestionable works of charity and of mercy; yet his name has not been suffered to descend to posterity unstained by obloquy, nor undimmed by malignant censure. It appears that accident first made him acquainted with the deaf and dumb; benevolence led him to the consideration how their wants might be supplied. He remembered that his tutor had once proved to him that there is no more natural connection between metaphysical ideas and the articulated sounds that strike the ear, than between the same ideas and the written characters that strike the eye, and that his tutor drew this conclusion:—that it was as possible to instruct the deaf and dumb by writing, always accompanied by visible signs, as to teach other men by words delivered orally, along with gestures indicative of their signification.

In the early part of de l'Epée's career he met with the work of Bonet before mentioned, and the enlarged treatise by Amman, 'Dissertatio de Loquela.' With these guides, aided by the enthusiasm which formed a part of his character, he pursued his task vigorously and with a certain amount of success; not with the success of some of his forerunners in the art, who had devoted themselves entirely and for years to individual pupils. The Abbé had a large number of pupils to whom he devoted his life and patrimony. Every one who has been a teacher knows well the degree of success which he may expect if his whole mind is concentrated upon the improvement of a few individuals, and the difficulties he may anticipate if his attention is divided among a great number of pupils. The Abbé appears to have made use of articulation in one part of his career, for he wrote a treatise on the mode of teaching by this auxiliary; this treatise was chiefly derived from the writings of Bonet and Amman. He employed dactylology, as it ever must be employed, so long as it is confined to the alphabet only, in a subordinate degree. Pictures he found an uncertain resource, and only useful in the earlier stages of instruction. Methodical signs and writing were the means on which he chiefly depended for the conveyance of intellectual knowledge. The employment of methodical signs for words is only the substitution of one artificial language for another. He established a connection in the mind of the pupil between these signs and the language of their country, but it is by no means satisfactory that he established a connection between these signs and the ideas which they were intended to represent.

The Abbé de l'Epée commenced his work by endeavouring to perfect a language of methodized signs as copious and accurate as the spoken language of a highly civilized country. He seems to have believed that he had only to do this to reduce the process of teaching the deaf to a mere translation. He appears to have lost sight of the fact that he had minds to cultivate and to fill with knowledge, and that without this cultivation the mere knowledge of words, the translation of words into gestures, and of gestures again

into writing, would be but labour lost. When he gave his pupils signs for words, he imagined that with the signs he gave them ideas, but he only gave them words. In acquiring a second language, those who already possess one have at command a comparative grammar which informs them to a certain extent of the value of certain words in certain connections with others; but the deaf have no such advantage; their natural and uncultivated language—gesture—is powerless for everything but the expression of their most ordinary wants; they have no separation of their ideas into classes, such as produce the parts of speech in more perfectly formed languages. Adelung mentions the inhabitants of the countries on the Asiatic continent as having ‘but one sound to signify *joyful, joy, to rejoice*; and that through all persons, moods, and tenses. The mere radical ideas are set down together, the connecting links must be guessed at. They form plurals as children do, either by repetition, as *tree, tree*, or by adding the words *much* or *other*, as *tree much, tree other*.’ *Mithridates*, v. i. p. 18. Thus it is with the naturally deaf, the radical idea is all that their gestural language is capable of expressing until modified by those arbitrary forms of speech which are the accessories of every polished language.

An example of the mode of communication which the Abbé de l’Epée adopted may be taken from his work. M. Linguet had observed that the deaf and dumb were demi-automatons. The Abbé addressed him, and a short time after Linguet visited the Abbé and his pupils. ‘I requested him,’ says the Abbé de l’Epée, ‘to propose at his fancy, some abstract ideas to be delivered by methodical signs to the deaf and dumb. As, out of compliment, he referred the choice to me, I addressed him to this effect:—“*Intellect, intellectual, intelligent, intelligence, intelligibility, intelligible, unintelligible, intelligibly, unintelligibly, unintelligibility*: here are nine words all generated from ‘intellect,’ to be expressed by distinct methodical signs. *Comprehensible, incomprehensible, comprehensibly, incomprehensibly; Conceivable, inconceivable, inconceivably; Idea, imagination, imaginable, unimaginable; Faith, credence, credible, credibly; incredible, incredulous, incredulity*: here, learned sir, is a cluster of abstract ideas, which shall be left to your option.” After some further little contest of politeness, he selected the word *unintelligibility*, doubtless conceiving it of greater difficulty than the rest. It was instantly rendered to the pupil and written down. While he was viewing it with eyes of amazement, I thus resumed: “Barely to produce the word you specified, learned sir, is a mere nothing. I will now unfold to you the means taken to prompt it by methodical signs; the exposition will not detain you long. Five of these signs were fully sufficient to designate the word; and you saw with what celerity they were given. The *first* signifies ‘not an external but an internal action;’ the *second*, ‘of reading the mind, that is exhibiting the disposition of apprehending the things proposed to it;’ the *third* announces ‘the possibility of this disposition,’ whence arises the appropriate noun-adjective, *intelligible*; which, being a concrete quality, is converted into the abstract by a *fourth* sign, forming *intelligibility*; and a *fifth* sign being added for negation, *unintelligibility* is produced.” By this and other examples M. Linguet was convinced that his expression was inaccurate and inconsiderate; but we need not follow out the examination which the pupils underwent in his presence. We have quoted this example in order to show the mechanical nature of methodical signs. That these signs were well qualified for dictation of words was sufficiently proved in the Abbé’s experience, but the words might be produced by the pupil from the signs of the teacher without their being understood, just as an ordinary schoolboy, unused to Latin exercises, might, from the dictation of his teacher, produce examples without understanding a single idea which they contained. These remarks are not made without some reservation; the Abbé professed to teach the meanings which the signs and words were to represent; but why did he not use the words only, without taking his pupils through a double mental process?

Herein is the great imperfection of the system of methodical signs, yet all his operations were not controlled by this peculiar system, and, when it was possible, the Abbé made use of the *natural* signs used by the deaf-mutes themselves, and interwove them with others of his own composition. Thus, in distinguishing gender, he says, ‘The gender is explained by putting our hand to our hat for the masculine,

and to the ear, the part to which a female’s head-dress extends, for the feminine.’ In the English institution the hand is placed to the beard to denote the masculine, and drawn along the forehead, in allusion to the parting of the hair, for the feminine. The following is the generally-received sign for singular and plural: ‘The elevation of the right thumb designates the singular, the motion of several fingers the plural.’ The following is also good: ‘To express doubt, we turn our head to the right, a *yes*, and to the left, a *no*; which of the two will take place we cannot tell; we shall know only by the event.’ Many similar examples might be adduced: how superior are these to ‘twirling two fingers round each other while declining, that is, while descending from the first to the sixth,’ to signify the term *case*; or ‘the left hand under the right for the noun-substantive,’ and ‘the right under the left for the adjective,’ will be readily perceived.

We do not regard the success of the Abbé de l’Epée as complete, but we are satisfied that he pursued his methods with openness and candour, and with the single desire of promoting the moral and intellectual advancement of the deaf and dumb. Heinicke of Leipzig, and Pêreire of Paris, must be regarded as his rivals, but he invited them to a discussion of the merits of the various systems, which they declined. While the good Abbé, with that frankness which formed a beautiful feature in his character, solicited the examination and the judgment of the learned upon his methods, his rivals shrouded their proceedings under a veil of mystery. The Abbé devoted his life and whole fortune, excepting a bare supply for his own wants, to the service of the class whom he had taken under his protection. Pêreire refused to disclose his methods except for a large recompense; and Heinicke, in addition to receiving payment from the rich, had four hundred crowns annually allowed him by the grand duke of Saxony. Both these persons made the art they professed an interested speculation; the Abbé de l’Epée only tolerated the rich—he was proud of being the instructor of the indigent. His successor, the Abbé Sicard, carried forward the principles of De l’Epée: he instructed his pupils in the elements of composition, a branch of their education comparatively new, and in which Sicard most completely evinced his superiority over his master. Sicard at first conducted a school at Bordeaux; on the death of the Abbé de l’Epée, Sicard was called to fill his place at Paris. The philosophical opinions and penetrating views which Sicard maintained and practised are well developed in his ‘*Cours d’Instruction d’un Sourd-Muet*,’ in which is developed the plan on which he conducted the education of his celebrated pupil Massieu. He followed the leading principles of De l’Epée, particularly in employing methodical signs as one of the chief instruments of instruction; he considered well the nature of language, and by his clear and analytical methods of sensible illustration, he contrived to make the leading principles of grammar familiar to his pupils. In the latter years of Sicard’s practice he thought more favourably of articulation, as a means of rapid communication between master and pupil, than he had done at the commencement of his career. The Baron Degérando says of his most popular work, ‘When we read the “*Cours d’Instruction d’un Sourd-Muet*,” we almost fancy that we are reading a kind of philosophical romance. It borrows its forms, and creates a similar interest; we find in it something of the romance of the Arabian Theophaïl (*Le Philosophe Autodidactique*); something which appears borrowed from the pictures of Buffon, the statue of Condillac, and the *Emilius* of Rousseau; it is a soul which has hitherto slumbered, which awakes; a hitherto darkened mind, which opens to the light; an intelligent life, which begins to develop itself, amid a variety of scenes, to the voice of the instructor; it is a kind of savage, strange to our customs, who is initiated into our ideas, our knowledge, and at the same time into our language. The Abbé Sicard enlarges upon each of these progressive stages, and he spreads over them the charm of a drama; he paints with warmth the uncertainties and the joys of the master and the pupil; and he succeeds in thus showing, in an animated picture, definitions and processes which appear the most barren in their nature; he gives a shape to the most abstract notions; it might be said that the Abbé Sicard is the *painter of syntax*, and the *poet of grammar*. This work went through several editions, and we need not be surprised at it, for it is not to the deaf and dumb alone that it may be profitable.’

Of the 'Theorie des Signes,' a work founded on the principles of the Abbé de l'Epée, we can only give a faint sketch. It is a kind of dictionary, in which the expressions of the face, and the attitudes of the body, for the communication of certain ideas, are described. The arrangement is not the ordinary alphabetical form of a dictionary, but a kind of logical order 'more conformable to the nature of things, and the growth and expansion of ideas.' The work is divided into twelve classes of things, adopting in each class an alphabetical order corresponding to the French language. These classes are arranged as follows:—

1. Signs of names of the most common objects, and such as come under observation during infantile years; these are the parts of the body, clothing, food, beverages, a town and its parts.

2. Vegetables, comprising forest-trees, shrubs, fruit-trees, culinary vegetables, medicinal herbs, wild plants, &c.

3. Minerals—gold, silver, copper, brass, lead, tin, iron, &c.

4. Of man—ages of man, relationships, school, institution, college, officers, domestics and servants of a house, tradespeople, mechanics, merchants; the liberal arts; titles, dignities in towns, cities, and states, and their functions; terms of war; ecclesiastics, and monastic functionaries.

5. Of God, angels, saints.

6. Of the elements, of fiery, luminous, and watery meteors; the firmament, earth, cardinal points, signs of the zodiac.

7. Parts of the world; names of nations, empires, kingdoms, republics, capitals, principal islands, &c.

8. Numbers, measures, weights, time, money, exchanges, commerce.

9. Organic qualities of man; abstract organic qualities of man; maladies of the body.

10. Qualities of matter; such as strike the senses of man, dimensions, shapes, surfaces, extent, quantity, lines, angles.

11. Physical actions of man, such as are expressed by verbs.

12. Intellectual and moral actions of man, expressed by verbs, nouns, adjectives, and adverbs.

These are the divisions Sicard adopted for his nomenclature, which occupies nearly the whole of the two volumes comprising the work, the latter portion of which is purely grammatical: in it the different parts of speech are considered not only under a general view, but under certain divisions which indicate their value, and assimilate those which bear a relationship to each other; thus adverbs of *manner*, of *number*, of *place*, of *quantity*, of *quality*, of *interrogation*, of *affirmation* and *negation*, of *time*, of *doubt* and *inquiry*, and of *comparison*, are distinctly and separately treated of. Without questioning whether the classification adopted in the twelve divisions of the 'Theory of Signs' be the best, we may see in such a classification the kind of gradations needful for supplying the deaf with an extensive nomenclature; and though few instructors would make the work a practical one, so far as to adopt the system of methodical signs there developed; yet, as a text-book, it unfolds a plan which any teacher may modify according to his own views. We think the work is less valued than it deserves to be, for as signs will, to a certain extent, be always in use among the deaf and dumb, especially in those institutions where they are educated, the theory of signs would be found of great use as a work of reference to all teachers. We need not panegyrize the Abbé Sicard; his exertions for the deaf and dumb are well known in this country, which he visited during the political troubles of France in 1815; his merits are acknowledged wherever the education of the deaf is pursued. We have sometimes been surprised that the 'Cours d'Instruction d'un Sourd-Muet' has not been translated into our language. Independent of its novelty and interest as connected with its more immediate design, its gradual unfolding of a great mind involved in moral and intellectual darkness, by a metaphysician of high endowments, presents some interesting psychological facts which would make it serviceable in general education; the illustrations of language and the development of ideas are just such as an accomplished and lively teacher would desire to place before his pupils to assist in conveying to their minds a just estimation of the value of words and the knowledge which they serve to impart.

In England, after the time of Bulwer, Wallis, Sibscota, and Daigarno, the art slumbered for many years. It was

revived by Henry Baker, the naturalist and microscopical observer, who taught dumb persons to speak, and of whom it is recorded by Dr. Samuel Johnson, that he once 'gave him hopes of seeing his method published;' he however kept the plan he followed secret. Of the extent of his success we know nothing, but it is said that the names of some of the first families in the land are among those of his scholars. [BAKER, HENRY.] About the year 1760, Thomas Braidwood had an academy at Edinburgh, where he taught the dumb to speak, and cured impediments in the speech. He professedly pursued the plan of Dr. Wallis, as developed in the 'Philosophical Transactions.' Articulation was therefore the chief instrument of instruction, and the principal medium of communication between the pupil and teacher. In 1783 Braidwood removed his school to Hackney, where he enjoyed for many years a deserved reputation for his successful application of the discoveries of his predecessors. [BRAIDWOOD.] Under him the late Dr. Watson became acquainted with those principles which he brought to much greater perfection than his predecessor, and developed in his work on the 'Instruction of the Deaf and Dumb,' and which he practised during his long superintendence of the Asylum in Kent Road, London. Indeed Dr. Watson was to Mr. Braidwood what Sicard was to De l'Epée; the disciples in each instance gave solidity and permanence to the systems of their respective masters.

The primary instruments by which the deaf and dumb are now generally taught, are *speech*, including *articulation* and *reading on the lips*; and natural or imitative signs. By these a communication more or less direct may be established between the teacher and the pupil. The subordinate auxiliaries are *writing*, *pictures*, *methodical signs*, and *dactylology*; the last may be *syllabic*, as employed by M. Péreire, or *stenographic*, as employed by M. Recoing, of Troyes, in the education of his deaf and dumb son. By this gentleman, *stenography*, in its wider sense, was also made available with success. We have seen that artificial articulation was among the earliest means resorted to as a medium of communication. Ponce, Bonet, Wallis, Van Helmont, Amman, Arnoldi, Heinicke, Péreire, Ernaud, Deschamps, Baker, Braidwood, and Dr. Watson, used their pupils to understand the speech of others and to speak themselves. The great advantage of speech is that it is the readiest method of intercourse between teacher and pupil. In teaching the deaf and dumb, the first object in view is to impart to him the language of his country; the second is grounded on this—to fill his mind with intellectual, moral, and religious truth. These two objects are generally made to accompany each other; the communication of knowledge in easy language familiarizes him with the use of language, and the exercises in speech are made the vehicle of valuable knowledge. In teaching vocal sounds to the deaf, the eye and the sense of touch are chiefly employed; the letters of the alphabet are classified; the sounds that are labial, dental, lingual, guttural, nasal, and those which are combinations of two or more of these, are taken in such an order that the pupil may discern differences in their similarities, and in some instances the organs of speech are shown, by means of drawings, in the required positions for the emission of certain sounds.

The open mouth, the widening lips, and part of the tongue, may be shown in the pronunciation of *a*, the nearly closed lips, hiding both tongue and teeth in *u*; in *b* the compression of the lips can be accurately shown, and the labial-nasal sound *m*, may be said to be exhibited in the closed lips, and by a line of dots to show the emission of air through the nostrils. It must be clearly understood that such drawings are chiefly useful in showing the positions of the organs.

Accompanying the exercise, the pupil must be made to notice the external organs of speech in his teacher, to feel the vibration with his own hand which sound creates in the trachea, and also to feel those emissions of breath which are caused by the production of certain sounds. He will be made to imitate such utterances; and by the exercise of patience and ingenuity on the part of the teacher, ingenuity chiefly directed to those little arts which refer to the mechanism of speech, and patience that will not be discouraged by repeated failures, the pupil will succeed in imitating what he observes, and in time he will accomplish what is required. In Wilkins's 'Essay towards a Real Character' there is a diagram of the positions of the organs

for producing vocal sounds, which may be consulted with advantage, though not in every instance accurate. While a pupil is engaged in acquiring the articulated sounds he may also be employed in writing the letters which they indicate, and in learning their shapes by the eye; he may also be initiated in the manual alphabet. It appears desirable that a system of syllabic articulation should be invented for the deaf; it would render the combinations of sounds more easy than at present, assimilating them more with spoken language. In Edgeworth's 'Practical Education' the consequence of teaching hearing children alphabetic sounds is thus exhibited. A child having learned the alphabet, and having to read the words *Here is some apple pie*, would, it is fairly enough suggested, pronounce thus: *Acheare ies esoeme apepele pewie*. This is not exaggerated; with hearing children, constant reading corrects the tendency; but numerous instances of this nature must and do occur among the deaf, who in many cases retain the first impressions they receive as to the sounds of letters. The medley of sounds which we heard a deaf person produce on attempting to utter the word *greyhound* a short time ago convinced us that a syllabic arrangement of sounds would, if practicable, be accompanied with many advantages. Of late years, artificial articulation, with or without the exercise of reading from the lips of a speaker, has come almost into general favour in the institutions for the deaf. At the London Asylum it has always occupied a prominent place; it has been most successfully introduced at the Royal Institution at Paris; it is also employed at Groningen, at Gudensberg, at Quedlinbourg, at Breslau, at Gmünd, at Pforzheim, at Zürich, at Sleswig, at Leipzig, at Munich, and at many other institutions, under the charge of eminent teachers. Not many of the provincial institutions of this kingdom make *speech* an object of the first importance; the principals of such institutions generally are convinced of its value as a vehicle for the transmission of knowledge, but do not make use of it, chiefly on account of its occupying more time than can be given to it, where a large number of pupils require attention, and where the funds will not support a sufficient number of instructors to enable them to teach it effectually. Of its value as a rapid mode of communication, after the acquirement is gained, the instructors of our country are well satisfied; and it is partially taught at the institutions of Manchester and Exeter. At the London Institution some of the pupils articulate not unpleasantly; their reading is monotonous, but their animation in ordinary conversations, especially on subjects of interest to them, gives a species of natural tone and emphasis to what they say.

Another primary auxiliary in the education of deaf-mutes is that modification of the language of gesture called natural signs. In this language the deaf and dumb take great pleasure; if unrestrained, it would be their only mode of communication with each other; and they appear to find in its resources all that is necessary to give life and force to their ideas. The quick changes of countenance which they exhibit, the sparkling eyes, the lighted-up features, the sarcasms, the sensibilities thus expressed; the transitions 'from grave to gay, from lively to severe,' all faithfully portrayed in the ever-varying index of their mind, speak at once in favour of this language as the truest mirror of their thoughts, hopes, wishes, and feelings, and inform us that this language is nature's most perfect, most expressive interpreter. To this rude though powerful mode of intercourse, which all the deaf possess in a higher or lower degree, those who are more intelligent add signs of description, by which they are able to explain facts and circumstances which have been brought under their observation. The teacher takes advantage of this method of communication to add to their stores of knowledge, to enrich and extend the sphere of their thoughts, to give them new food for the mental operations, all of which may be accomplished during the time that words and the language of their country is imparted to them. Thus a conventional language is formed which assists in their intellectual culture, increases their happiness, and shows them in some degree the connexion which exists between themselves and the objects by which they are surrounded. In many institutions this use is made of signs: new knowledge is most effectually communicated by their aid. The sixteenth report of the New York Institution for the Deaf and Dumb furnishes an example of which we can avail ourselves to show the great benefit of signs in the business of instruc-

tion. The natural signs for the words in which the sense of the sentence is comprised will readily occur to the reader. 'Let it be supposed that an instructor should wish to produce the following sentence: "A horse runs away with a boy, throws him off, and kills him." It is not at all probable that such a combination of circumstances would occur at the moment, and thus enable him to take his pupils to the window and point them out. He must have recourse, then, to signs. It is immaterial what selection of place and circumstance is made, provided only that the facts to be enunciated are clear and prominent. The scene of the occurrence may be laid in the city. The boy is riding slowly along, staring at the multitude of new objects which meet his view, and wholly forgetful of his horse. Suddenly a military company appears from a cross-street, with drums beating and colours flying. The horse becomes frightened and beyond control: he dashes through the street at a furious rate. The boy clings to the saddle, but is at length thrown with violence on the pavement. The blood is seen spouting from his mouth and nostrils. People gather around and raise him up. They feel his pulse; but it has ceased, and the breath of life is gone: the boy is dead. During this description, the class are looking most intently on the instructor. Every eye is fixed, and every countenance full of expression. He has now obtained every thing for which he laboured. Their ideas and notions of the fact are as clear and explicit as his own; and it only remains to express them by written language. To imagine, as some have done, that this process of writing is a *translation* of signs into language, is wholly erroneous. It is no more a translation than the same expression of a speaking child would be, when the casualty should actually occur.' To this we will only add, that the rapidity with which such a description is conveyed to the pupils is inconceivably great, and takes very little longer than the communication of the occurrence vocally, in its shortest form. But the disadvantage attending such a mode of intercourse, when a language has to be taught, is not recompensed by its rapidity, as the words and the syntax of spoken languages are not employed in such descriptions; the pupils are consequently left ignorant of the grammatical construction of sentences. It is therefore found necessary to unite natural and descriptive signs with writing or dactylology, in the use of which the idiom of the maternal language is preserved. Most of the English and American institutions employ the signs we have described; this auxiliary is also employed at Paris, at Yverdon, at Vienna, Toulouse, Nancy, Besançon, Bachtelen, Pisa, and at several other institutions. Mimic signs will always possess this advantage to the deaf over every other mode of intercourse, that they present to them a lively picture, in which facts and circumstances can be constantly and instantaneously reproduced; they address themselves immediately to their perceptive powers, and lead them intuitively, and by a direct process, to form just connexions and conclusions; while our conventional tongues, whether addressed to them by articulation, by writing, or by dactylology, act upon them by the circuitous paths of association, and the habit which they long follow of converting our language into their own.

One important influence which the mimic language exercises on the intellectual development of the deaf has yet to be noticed. This results from its employment among themselves. Much of the knowledge which the younger pupils of an institution obtain is through this medium. The lessons of the teacher for many months have less influence on the minds of his pupils than the intercourse with their associates. This is a powerful argument for bringing up the deaf and dumb in public rather than in private schools. Independent of the stores of knowledge which an assemblage of deaf-mutes bring from the districts in which they have lived, the fruits of their personal observation and experience, the events that have occurred within the walls of the institution, particularly as they bear upon actual occurrences, are handed down by mimic and descriptive signs from one generation to their successors; and a very valuable and available store of intelligence is thus preserved, which at the same time contributes to the formation of character and familiarizes the pupil with the use of this species of language. Respecting *methodical signs* we need add nothing to what has already been said of the method of the Abbés De l'Épée and Sicard. We think they are not much used at the present time in the education of deaf-mutes.

It has been stated that the other aids employed in developing the minds of the deaf are subordinate to those which have now engaged our attention. *Writing* is employed in all institutions; it is an art which is soon acquired sufficiently well for all school purposes. At first it engages the attention of the pupils, while they endeavour to form on their slates those combinations of letters, the meaning of which has been conveyed to them; and thus it relieves the teacher and employs a new set of faculties in the pupils. This slow but permanent repetition of their lesson assists in fixing the forms of words, and the matter conveyed by them, in their minds. At a later stage, it exercises similar influences upon them in a higher degree, and it is, besides, the instrument by which they give permanency to their thoughts and observations in those *compositions* which form an important exercise in these seminaries. It is also the medium to which they chiefly have recourse among strangers, and among their friends, if they find their articulation is imperfect, and their signs are not well understood.

Dactylology is another auxiliary in almost universal use. For a more particular view of the utility and value of this instrument of instruction we refer to the article DACTYLOLOGY.

Pictures and the art of drawing are valuable helps at the commencement of instruction. A collection of all objects cannot be made, nor can objects be so conveniently referred to as representations of them. Either by reference to pictures or real objects, the first lessons are conveyed to the deaf, and they impart an interest to the exercises which no other means could supply. To those who have not well considered the subject, it is a matter of surprise how much of language can be represented by a graduated series of engravings, or even by the rude sketches which a teacher can draw upon his tablet whenever they are wanted, to elucidate the subject which he is desirous to impress on the minds of his pupils. In the work of Bébien, the successor of Sicard (*Manuel d'Enseignement Pratique des Sourds-Muets*), the pictorial art is employed to exemplify substantives, their gender and number, adjectives, the cardinal numbers, fractional numbers, verbs neuter and active, personal pronouns, prepositions, articles, and degrees of comparison; many other portions of language may be explained by diagrams. Drawing is thus of essential service, and the pupils often have recourse to the advantages it offers for any communications which they think will be better comprehended through its medium than others. This art is therefore encouraged, and in many institutions direct instruction is given to the pupils from an early period of their education.

The auxiliaries we have now indicated are used for the conveyance of all kinds of knowledge; in some branches of study one may have a preference to others, from its being better adapted to their elucidation. Thus geography will always be taught from maps, geology from sections, geometry from diagrams; pictures will be used to describe historical events; and signs will be in requisition for the illustration of the arts and trades of men, as well as for showing the manners and customs of distant nations. Collections of metals, minerals, vegetables, animals, animal substances, vegetable substances are of the highest value, and furnish direct evidence of properties and changes which cannot be described. It will even be necessary occasionally to call in the assistance of the workshop and its implements, the laboratory and its apparatus, in order to perform experiments, and to exhibit processes before their eyes; and while the excitement prevails, to make use of the opportunity to communicate not only knowledge, but the primary aim of all instructors of the deaf and dumb—*language*. Having the latter, the attractive form in which knowledge is presented will raise in them a desire to possess this also, and the object of the teacher is fully accomplished.

The period allowed for instruction in the public institutions for the deaf and dumb varies in different countries; in few cases is it so short as in England: in nearly all the continental institutions of celebrity it is considerably longer. With us only five years in most instances are allowed for the education of pupils, who are wholly or partially sustained by the funds contributed for their support. Throughout France, Switzerland, Würtemberg, Sweden, and Poland, the pupils are permitted to continue six years. At the institution of Groningen, and at those of Copen-

hagen and Sleswig, the pupils remain seven or eight years; at Vienna from six to eight years; at Berlin they continue from six to nine years; and at Leipzig for a like period. Should no other modification of the institutions of Great Britain take place with regard to the duration of a pupil's continuance in them, it would be well if some provision were made to enable pupils of superior talent, and those intended for the more liberal arts and trades, to continue under special instruction, to qualify them for their future business, for a longer period than those who need no such preparation. Nearly every boy may learn to make shoes, to hew wood, and to draw water; but it requires a peculiar training to form artists, engravers, clerks, carvers, modelers, and superior mechanics—arts in which there is nothing to prevent the deaf and dumb from excelling.

The subjects on which instruction is imparted must necessarily vary with the length of time given to education. The following plan of a course of instruction cannot be satisfactorily accomplished in less than six years; it is, however, an approximation to what is attempted in some of the British institutions. We have already noticed the instruments of teaching, and shall proceed to mention the matter of instruction and its division with regard to time, which is assumed to be pretty nearly what is actually accomplished. With regard to a sixth year, were our institutions so modified as to enable the pupils to be kept for such additional time, it would generally be devoted to confirming the pupils in their previous acquirements, to a repetition of subjects of more than common interest, and to special instruction, according to the dispositions and endowments of the pupils, connected with their future destination. In short, it should in every way be made a retrospective year as regards their school acquirements, and prospective as to their future interests.

The subjects for instruction are:—

Language, including nomenclature and syntax.

Writing, as an acquirement, and a means towards higher attainments.

Reading, by dactylology or by articulation.

Religion and morals, preceptal and applied.

Geometry and mechanical drawing.

Geography, physical and political.

Arithmetic, elementary and applied.

Drawing, as an art and in connexion with design.

History, antient (from the Old Testament).

History, modern (of England especially, and exemplary biography).

History, natural (animal, vegetable, and mineral kingdoms).

Physics (properties of natural bodies, astronomy, mechanics, chemistry, &c).

Composition (to induce the ready use and application of language).

The *first year* would be generally devoted to instruction in language by means of natural signs, dactylology, or articulation, and writing. Instruction in numbers and their combinations by sensible objects, by manual notation [DACTYLOLOGY], by figures, and by words. Occasional instruction in moral and religious duties by signs.

Second Year.—Instruction in language continued by the same instruments as in the former year; in arithmetic. Geography commenced with ground-plans of school-room, house, and neighbouring grounds, streets, roads, fields, &c. Lessons on form, introductory to geometry. Moral and religious duties. Composition, commenced by pupils writing down their own observations on facts and occurrences in short sentences.

Third Year.—Language continued; the two former years are chiefly given to nomenclature; syntax will now more especially demand attention. Lessons continued in geometry, geography, arithmetic, physics, and composition. Scripture history and drawing commenced.

Fourth Year.—Language continued, and especially applied to composition. Direct instruction continued on all the subjects named for the preceding year.

Fifth Year.—In addition to bringing the branches of knowledge commenced to a close, abstract ideas and figurative language; doctrinal religion; the human body, its parts and organs; the moral and social duties of man, his dispositions and faculties, should be brought under consideration during this year, and continued for as long a period as the pupil remains under instruction. Those parents who can afford to continue their children as private pupils might

have them instructed in every department of a sound English education, and, if they thought proper, qualified for the more liberal arts and professions; for there exists no insurmountable barrier to the acquisition of classical learning, mathematical and scientific attainments, and a knowledge of the modern languages.

The foregoing outline of a course of instruction for deaf-mutes is somewhat similar to what is actually in operation at the Royal Institution of Gmünd, Würtemberg, which is under the direction of M. Jaeger.

After the explanations into which we have entered on the modes and subjects of instruction, no lengthened remarks on the processes seem to be requisite. In teaching substantives the object is pointed out, and the name is written, spelled on the fingers, articulated, or signed, as the medium of communication may be; all these are so many modes for expressing the object referred to. Thus if *man* be the object, it is pointed to, or the word *man* is presented before the eyes of the pupils, or it is spelled by means of the manual alphabet, or it is pronounced, or the beard is touched, and the height of man is indicated. In the same manner other names of objects are conveyed to the pupils, who soon see that a connexion exists between *our* conventional signs and objects, as well as between *their* conventional signs and objects. Adjectives are taught in a somewhat similar way; the colours are as easy as any other qualities to introduce pupils to this class of words. A few wafers, all of the same size but of different colours, are good mechanical aids. When the colours are known the teacher will pass on to other adjectives. The nature of the indefinite article is easily exhibited; the definite can only be acquired by practice, in the manner of hearing and speaking children. Verbs of action are easily imitated by signs, and the pupils are prepared to expect that there are words to indicate *action*, as well as *objects*, *number*, and *qualities*. Adverbs, which indicate the manner of an action, naturally follow verbs; to *run quickly*, to *walk quickly*, to *walk slowly*, may, it will be seen, be accurately conveyed by the means employed to bring instruction so immediately under the cognizance of the senses. The possessive, demonstrative, and personal pronouns are exemplified by real facts which come under the observation of the pupil, or which are purposely contrived to arrest his attention. Many of the prepositions and conjunctions can be rendered sensible and intuitive; other particles are taught by diagrams, and by examples produced as occasion requires, and reproduced by the pupils from instances supplied by themselves. The moods and tenses of verbs, and the auxiliary verbs, can only be taught effectually by the events and casualties which bring them into use in ordinary life; these are constantly occurring, and it is the business of the teacher to turn them to account for the improvement of his pupils. Abstract ideas must be traced downwards to those simple ideas from which they originate; indeed the constant application of analysis and induction, which is continually called forth in conveying instruction as far as may be through a sensible vehicle, renders this office of language more easy than can be conceived by those not accustomed to employ such powerful instruments in the process of education. Figurative expressions, comparisons, similes, metaphors, require a series of progressive lessons, in which language should be employed to illustrate each step from the easiest to the most complicated figures of speech. Examples might be taken from the Scriptures, from fables, allegories, and parables; they should be especially written with a view to utility, and adapted for the explanation of such subjects as occur in any course of education. Though in the plan marked down we have given two years to *nomenclature*, and have not recommended the commencement of *syntax* till the third year, it is not intended that this shall interfere with the pupil's gradual introduction to small sentences expressive of sensible ideas. Indeed the progress in language of a deaf and dumb pupil, to be successful, must be assimilated as nearly as possible to the progress of other children, and he must be continually accustomed to those ordinary exemplifications of language, affirmative, negative, and interrogative, which other children use, and which advance in complexity as their years increase and their minds become enlightened. As the manner and substance of a child's conversations indicate the society in which he has been brought up, and the educational advantages he has received, so will the ordinary remarks and compositions of the deaf and dumb exhibit the benefits they have de-

rived from the means employed to bring them into communion with society, and to elevate their thoughts and understandings to the level of those who labour under no such deprivations.

The public establishments for the reception and education of the deaf and dumb of England are situated respectively at London, Birmingham, Manchester, Liverpool, Exeter, and Doncaster; those of Scotland at Edinburgh, Glasgow, and Paisley; and those of Ireland at Claremont near Dublin, and Belfast. The asylum at London, situated in the Kent Road, was opened in 1792; it was the first asylum in the kingdom for extending to the indigent deaf and dumb the benefit of education, and, from its establishment to the present time, nearly 1500 pupils have been received and educated there. A bust of the Rev. John Townsend, which is placed in the committee-room, perpetuates his memory as the founder of the institution. Two hundred and twenty children reside in the asylum, which receives ample support from the wealthy in all parts of the kingdom; indeed it possesses, besides its annual receipts from subscriptions, donations, and legacies, a funded property of probably not less than 100,000*l.*, by which its permanent income is greatly increased. The instructor of the asylum is Mr. T. J. Watson, a son of the late Dr. Watson; he is assisted by twelve male and two female teachers. The whole is under the management of a committee. The cost per head of each pupil is much greater at this establishment than at any other of a similar kind in the kingdom. To an extent this may be accounted for in the greater display which an institution in a wealthy metropolis is expected to make, and also in some measure from the articles of maintenance being dearer than in the provinces.

The second institution which came into operation in this kingdom was that of Edinburgh, which was established in 1810, and at first placed under the care of Mr. Braidwood; he was succeeded by Mr. Kinniburgh, who has continued to conduct the education of the children to the present time with the greatest success. The number of children at present under instruction is sixty. Mr. Kinniburgh has two assistants. The institution has occasionally had to struggle with difficulties from want of funds, and its usefulness has consequently been much circumscribed. Lately, a ladies' association has been formed, whose funds have already placed nine children in the institution; and it is believed that by the means thus brought into operation, all needful help will be afforded for the ordinary wants of the charity.

The general institution for the deaf and dumb at Edgbaston, near Birmingham, was opened in 1814. It was formed in consequence of a lecture on the subject which was read by the late Dr. de Lys before the philosophical institution of Birmingham. This gentleman, and Dr. Alexander Blair, late professor of English literature in the university of London, are to be regarded as the first promoters of the institution. It was placed under the superintendence of Mr. Thomas Braidwood, one of the sons of Mr. Braidwood of Hackney. On the death of this gentleman in 1825, M. du Puget, a Swiss Protestant, and a pupil and teacher in the seminary of Pestalozzi, at Yverdon, was appointed to the charge of the institution. For many years the establishment was confined in its means, but it is now rising into prosperity, extending its buildings, and increasing its number of pupils. About fifty pupils are at present received. M. du Puget has a male and a female assistant; the management of the house is superintended by a matron. The funds are at present rather more than adequate to the expenditure; they are derived from donations, subscriptions, and legacies.

The national institution for the deaf and dumb of Ireland is situated at Claremont near Dublin. It owes its origin and progress to the strenuous and unwearied exertions of Dr. Charles Orpen. Soon after its commencement in 1816, it was placed under the care of Mr. Joseph Humphreys, who has continued to be the instructor to the present time. The number of its pupils was limited during the early existence of the institution, but in consequence of the active operations of numerous juvenile associations during more than ten years, it has now funds and accommodation for the education of about 130 pupils, the number under instruction. Mr. Humphreys is assisted by three male and three female teachers. A workmistress, a shoemaker, a tailor, and a gardener, form also a part of the establishment. These

persons instruct a certain number of the pupils in their respective employments. At this institution there is a very complete library of works on the education of the deaf and dumb.

The Glasgow institution, formed in 1819, has had several teachers. Its present master is Mr. Duncan Anderson, whose persevering efforts have raised it to a high degree of prosperity both as to rank and character. It contains sixty pupils. It has no fund more permanent than that derived from payments of pupils, donations, legacies and annual subscriptions. Mr. Anderson has one assistant. The work of the girls is superintended by the matron.

The school for the deaf and dumb at Manchester was opened in 1824. Mr. Vaughan was appointed master; he had been an assistant for several years to Dr. Watson at the London institution. The accommodations of the building were only calculated for 50 children, and in a few years after its establishment many applications for admission were annually rejected. A fund has been subscribed for the erection of a commodious building which is now in progress. The death of Mr. Vaughan took place in 1834; his labours and talents have received honourable testimony in that town. The school has been lately committed to the care of Mr. Bingham, a teacher of much experience, at first as an assistant at the Birmingham institution, and afterwards as the master of that at Exeter.

The Liverpool school owes its origin to Mr. William Comer of that town: it was opened in 1825, and commenced as a day-school, but its original plan has undergone some modifications, and its pupils are of the mixed character of boarders, day-boarders, and day-pupils. Several changes have taken place in its mastership; the present teacher is Mr. Rhind, lately an assistant at the London asylum. This school contains 48 pupils.

The West of England institution for the deaf and dumb was established in 1827. It is situated at Exeter. Its especial object is the 'instruction of the deaf and dumb resident in Devon, Cornwall, Dorset, and Somerset.' Like the others it is supported by subscriptions, donations, legacies, and by payments on behalf of the children. Its funds are about equal to the maintenance of fifty children, the number at present in the institution; there are also six pupils who pay liberally for their education. Since the removal of Mr. Bingham to Manchester, the credit of this institution has been amply sustained by his successor, Mr. Gordon. The assistants are one male and one female. The superintendence of the domestic arrangements is confided to a matron.

The Yorkshire institution for the deaf and dumb, situated at Doncaster, is the latest formed in this kingdom. It was commenced in 1829. Throughout its whole course it has been prosperous. Its funds have gradually increased, chiefly in consequence of the exertions of the Rev. W. C. Fenton, its first promoter; it has been enabled to admit every applicant, and for several years a portion of its income has been set aside towards the establishment of a permanent fund. The interest derived from this source at present supplies the annual falling off of subscriptions by deaths and other casualties. Seventy pupils partake of the benefit of the institution, which is under the charge of Mr. C. Baker, and four assistants, two of whom are deaf and dumb. A workmistress has the care of the girls out of school hours, and the domestic arrangements are superintended by a matron.

All these institutions are under the direction of committees chosen from the subscribers residing in or near the towns where they are situated; these committees appoint masters and other officers not chosen at the annual meetings; they establish the general rules of the institutions which they control, but they do not interfere with the course of instruction. One or more examinations of the pupils take place in the course of each year, which the subscribers and the public generally are invited to attend.

In some of these institutions instruction in trades is blended with intellectual instruction; such are those of Dublin and Exeter. In others, industrial occupations are chiefly used as furnishing exercise or a change of employments; of these the institutions of Birmingham and Yorkshire are instances. The schools at Paisley and Belfast are merely day-schools. In most of the institutions there are three classes of pupils; the most numerous are the poor, who are either instructed gratuitously, as at London and Manchester, or who pay a small sum, varying from 2s. 6d.

to 3s. 6d. per week, as at Birmingham, Exeter, and Doncaster. These sums are paid by the parents or friends of the children, or by the parishes to which they belong. In the latter case, it has often been found a difficulty to convince overseers of the policy of educating their indigent deaf and dumb, and thus restoring them to society; but under the operation of the new poor law, section 56 (a clause which was introduced by the Earl of Harewood), the difficulty is in some measure provided for; permission being there given for the advance of sums for the 'deaf and dumb and blind.' The second class of pupils received into our institutions are those whose parents can afford to pay their expenses, so that no burden is in such cases imposed on the funds subscribed for charitable purposes. The payment is generally 20l.; this being about the average expense of pupils in the provincial institutions. The third class of pupils are those whose friends can afford to pay a large sum for their education; 80l., 100l., and in some instances more, is the payment required from this class. The number of such pupils being very limited, the masters of institutions are generally allowed this privilege, or a proportion of the income arising from this source is assigned to them.

There are 8000 deaf-mutes in England; the institutions at present in operation are not capable of educating more than 600. It is calculated that at least one-eighth of the whole number are within the age and other qualifications generally prescribed for education. It therefore seems necessary that more extended provisions should be made for their instruction. The densely populated country between the Tees and the Cheviot Hills appears to be an eligible district for the support of a public institution of this kind; and as large towns are in all respects preferable to small ones, offering greater educational advantages and permanent settlements in after-life, the rapidly improving town of Newcastle suggests itself as a proper locality for such an establishment. Another institution should be established in the intelligent and populous city of Norwich, which might include the counties on that portion of our coast. A third desirable point for an institution seems to be Caermarthen, which would take in the whole of Wales, and be conveniently situated for the populous manufacturing counties of Glamorgan and Monmouth. Such is the feeling of interest with which the deaf and dumb are regarded, that it has frequently been only necessary to make known their wants to procure for them that sympathy and aid which their circumstances require.

The adoption of a few simple measures would immediately tend to place the education of the deaf and dumb in this country much higher, and make it more permanent than it has ever been. At present each teacher follows his own plan, for he has no means of learning those of other teachers. The systems are all more or less modified from general principles which have been long known. The matter of instruction and the processes vary in a greater or less extent in different schools, and take their complexion from their respective teachers. The experience of one and the ameliorations introduced into his practice are unknown to all the others. A centre of union is wanted in which the successful expedients of all shall be accumulated. But we do not see how it would be feasible to form such a centre without exciting jealousy and distrust. We have therefore to consider how these institutions might mutually serve each other without endangering that unanimity which it is desirable to preserve among a number of individuals engaged in the same labour of benevolence and charity. The course we would suggest is, that each instructor should draw up an outline, with sufficient detail to make it intelligible, of the branches of study taught in his school; that he should explain generally those processes by which he obtains his results; state the average extent of progress made by pupils in half-yearly or yearly periods throughout the term of education; the portion of school discipline and instruction under his own peculiar charge; and that portion which is confided to the assistants; the arrangements for the management of the pupils when not in school, including physical education and industrial employments. Such outlines would have a direct and immediate tendency to assimilate conflicting systems, and to lead to the adoption of processes which would produce the most satisfactory results. The expense of printing 200 copies of a pamphlet of this nature would be under 5l.; it might be transmitted to all institutions, and those left would be sold to visitors, and defray the cost of printing thus incurred. Nearly all

the institutions in this kingdom publish a report annually. These reports never hint at methods of teaching, and speak only in very general terms of the results produced, state the difficulties or successes of the preceding year, proclaim the continued good conduct of masters and matrons, sometimes acknowledge their talents and industry, and as a consequence allude to the progress and improvement of the pupils. With such remarks, and a statement of the income, expenditure, list of subscribers, and regulations, the publications we have alluded to are generally filled, and perhaps it is all that is needful to satisfy the public generally and the subscribers in particular. The 'Circulaire' of the Royal Institution of Paris is a very different production. It is designed to accumulate, diffuse, and perpetuate the plans pursued in all institutions in correspondence with it. It is stated in the third circular, that thirty-seven institutions have co-operated with the Paris institution in this labour. Since the commencement of this publication, the institution of New York has published two reports, the sixteenth and seventeenth, which are chiefly devoted to the explanation of the principles and practice followed in that institution; and it is to be hoped that the British institutions will adopt some course by which the intelligence and ability evinced in their management may be more widely diffused. No work exists in the English language worthy of ranking, either in theory or practice, with many in other European languages. In France there are the writings of Sicard, the classic production of Degérando, the practical illustrations of Bèbian and Piroux, and the exciting volume of Paulmier. There are besides a host of others, from which much solid satisfaction may be derived. In Germany there are the writings of Wolke, of Daniel, of Venus, of Schwartzer, of Neumann, and many more. We want, in the English language, a full explanation of those principles on which the education of the deaf and dumb rests, and an insight into the philosophy on which such principles are founded. We want also practical lessons, introductory to other school-books, and forming an elementary library or literature for the pupils. No persons are better qualified to write good school-books than those whose practice is founded on a sure theory; the teacher of the deaf and dumb cannot teach *words* alone; an acquaintance with *things* is essential to his pupils' progress; in this respect his instructions are beyond comparison more valuable than those conveyed to the children in the generality of our schools, and his school-books might be introduced into common education with advantage.

The provision for a succession of teachers of the deaf is in our kingdom very inadequate and insecure. The emoluments of principals in the provincial institutions vary from something more than 150*l.* to 350*l.* a year; the assistants receive from 10*l.* to 50*l.* a year, in addition to board. The principals are generally men of education, of acknowledged ability, and of long experience. With one or two exceptions, the principals of the public institutions for the deaf and dumb in the United Kingdom have been engaged in their present occupation from ten to twenty-five years. When such men from any circumstance quit their profession, it would be natural to suppose that their situations would be easily supplied from the number of assistants educated by them; but the difficulties in which several institutions have been placed show the contrary. The committees of the Dublin, the Birmingham, and the Liverpool institutions have at different times experienced such difficulties. Intelligent assistants will not permanently connect themselves to a profession in which the chances of succeeding to a head-mastership are so few. They therefore take the first opportunity to embark in some occupation which promises more satisfactory hopes of advancement; thus the training they have undergone is thrown away; or, it has been, that such assistants are considered too young to be intrusted with the charge of an establishment where both sexes are committed to their control; for the arrangements of the matron are subordinate to those of the master, and much of her power even with regard to the girls must be derived from him. It seems desirable to devise some plan by which the situations of second-masters shall be rendered permanent, and this can only be done by such an increase to their income as shall bind them to their profession. It cannot be expected that committees of institutions should augment these incomes from their funds; they might thus pay a security for services for a series of years, which would

never be directly beneficial to the institutions under their management. A few hundred pounds granted annually from the state would at once remove the difficulty, and enable each second-master to receive from 80*l.* to 100*l.* a year, in addition to his board. Fifty pounds a year granted from the government to the second-master of each institution, to be added to his salary after he has attained the age of twenty-one, and provided he has been engaged as a teacher of the deaf and dumb three years, would remove this difficulty, and furnish an intelligent and experienced class of head-masters, whenever vacancies should occur for such appointments. These persons would also, from the facilities they would acquire in imparting knowledge to the deaf and dumb, become admirable teachers in every branch of primary education. They might take departments in normal schools; they might become superintendents or inspectors of districts of common schools; and when such removals took place, their situations in institutions for the deaf would be filled by the junior teachers. Such assistance as this would not interfere with the established plans of any institution; it would cost the government but little, and very great advantage would be derived from it. In some states the entire cost of educating the indigent deaf and dumb is defrayed by the government; in others a large portion of the expense is thus sustained. It does not therefore seem too much to expect that England should contribute towards providing a supply of teachers for an occupation so useful and so important to the well-being of a large number of the community. The noble decree of the king of Denmark is worthy of imitation: 'Every deaf and dumb child born in this kingdom shall receive the education necessary to render him a useful member of society.' The number of institutions for the deaf in Europe, and some particulars, are given in the table below.

Countries.	Population.	No. of Deaf and Dumb.	No. of Institutions.	Pupils under Instruction.	No. received annually.
Portugal	3,215,000	2,407	1	20	
Spain	11,500,000	7,255	1	30	
France	32,000,000	20,189	28	793	159
Italy	20,000,000	12,618	5	147	29
Switzerland	2,000,000	3,976	5	80	16
Austria	26,444,000	16,684	6	197	39
Prussia	12,726,823	8,223	18	314	62
Other German States	9,905,475	8,283	28	410	81
Hanover	1,500,000	946	1	10	2
Holland and Belgium	6,166,584	2,166	5	249	50
Denmark	1,800,000	1,260	2	190	38
Sweden and Norway	3,800,000	2,397	1	40	8
Russia	44,118,000	27,834	2	111	22
United Kingdom	23,365,807	14,328	12	745	149

With respect to the capabilities of the deaf and dumb for instruction, and the means by which instruction may be imparted to them, the following principles are firmly established:—

1. That the deaf and dumb are naturally equal to other persons in their intellectual faculties and manifestations.
2. That these faculties may be developed by means of articulated language, or by natural and descriptive signs, accompanied by writing.
3. That the less important auxiliaries in the instruction of the deaf and dumb are dactylology, writing, drawing, and the use of pictures.
4. That by these means the mother-tongue can be perfectly taught to the deaf and dumb; and,
5. That during instruction in language by the above auxiliaries they may also acquire the elements of an ordinary education.

The suggestions offered in the course of this article, for improving and extending the education of the deaf and dumb, are as follow. We doubt not but the co-operation of philanthropists, committees, and teachers would, in a very few years, effect all these ameliorations.

1. That the schools at present in operation in this country are insufficient for the instruction of the number of deaf and dumb persons ascertained to be within the usual ages of education.
2. That the time necessary for the common education of a deaf and dumb person, according to the experience of those best informed on the subject, is not less than six years.
3. That the education of the indigent deaf and dumb should be made imperative on the parishes to which they belong.
4. That some means, by the press or otherwise, are neces-

sary for making known the principles, the practice, and the experience of the various institutions.

5. That it seems desirable, in order to secure a succession of experienced teachers, that the government of the country should be solicited to furnish means for augmenting the salaries of second-masters in the various institutions.

The following deductions regarding deafness may be assumed to be correct; they are founded not only on the facts communicated at the commencement of this article, but on many other documents, the general accuracy of which cannot be doubted:—

1. That deafness is not always hereditary, though it is found in families, and often among collateral relations.

2. That the diseases to which infants are liable are a fertile source of deafness.

3. That the deaf are in many cases subject to other diseases, the principal being those of a scrofulous tendency.

4. That the manufacturing and agricultural portions of this kingdom appear, about equally, to furnish instances of the calamity.

5. That a perfect system of registration would tend to furnish a correct census of the deaf and dumb, and would exhibit many facts calculated to throw light on some of the causes of deafness.

NOTE.—There is considerable discrepancy in the statements of the various institutions as to the number of persons born deaf and the number becoming so after birth, as will be seen in the following view:—

	Born Deaf.	Became Deaf.	Uncertain.	Total.
Paris . . .	52	37	13	102
Yorkshire . .	75	26	9	110
Dublin . . .	423	66	—	489
Hartford, Conn.	116	135	28	278

American Institutions.—The first institution for the deaf and dumb in America was established at Hartford, Connecticut, in the year 1817. It originated in the desire of the late Dr. Cogwell, to promote the education of his own daughter, who was deaf and dumb. The first instructor at this institution was the Rev. T. H. Gallaudet, whose useful publications for children have been widely circulated in this country. He visited the institution at Paris, then under the charge of Sicard and Bébien, and on his return to America he was accompanied by Mr. Clerc, who was at that time the 'glory and support' of the institution at Paris. The early instructors of the institution at Hartford were men of high literary reputation: among them were Mr. W. C. Woodbridge, the editor of the 'American Annals of Education,' Mr. Lewis Weld, for some years the instructor at the Philadelphia institution, and at present the principal of the Hartford institution, and Mr. Harvey P. Peet, the present principal of the New York institution. The Hartford institution has also supplied instructors to all similar establishments in the United States. For several years the number of pupils instructed in this institution has been 130. We find from the seventeenth report (May, 1833), that 25 pupils were supported by their friends; 38 by the state of Massachusetts; 20 by Vermont; 16 by Connecticut; 15 by New Hampshire, and 16 by Maine. There are eight assistant-teachers in addition to the mistresses who conduct the education of the girls in female duties and occupations.

The New York institution was commenced in 1818. It had at first to contend with differences of opinion as to the system of instruction, and several changes of masters were the consequence of this indecision. In the year 1827 the legislature of New York, by which the institution was chiefly sustained, authorized Mr. Flagg, the superintendent of common schools of the state, to visit this and other institutions, and to compare the results of the different systems of instruction. Mr. Flagg therefore visited the schools at New York, Hartford, and Philadelphia, and in his report he gave a decided preference to the system of the two latter institutions, and he recommended the directors to engage an instructor acquainted with the improved modes of teaching there pursued. Mr. H. P. Peet was accordingly engaged as principal of the New York institution, and the school is at present conducted by him with great ability. There are seven teachers, a matron, an assistant-matron, and five instructors in trades. The trades, which are taught in the intervals of school-hours, are those of a cabinetmaker, a shoemaker, a bookbinder, a tailor, and a gardener. One

hundred and forty pupils partake of the benefits of the asylum, of whom 102 are supported by the state of New York; 9 by the corporation of New York; 2 by the commissioners of the Alms-House, New York; 7 by New Jersey; 6 by the institution; 1 by the supervisors of Dutchess County, and 13 by their friends. (See 17th *Annual Report*, 1836.) The reports of this institution are of a highly valuable nature; for, independent of their local and temporary interest, they contain some of the best essays in the English language on the practical instruction of the deaf and dumb. The building occupied by this institution is both splendid and convenient; it is surmounted by an observatory, which is 70 feet above the ground, and which commands an extensive prospect. The institution possesses a library of works on the instruction of the deaf as ample as can be procured at the present time, in the collection of which neither expense nor labour have been spared. The circular issued by the directors on the course and manner of instruction is an interesting and satisfactory document. The principals of the New York and Hartford institutions are not personally occupied in the work of instruction. The different classes are each under the care of a separate teacher, and the principal gives a general superintendence to all, and regulates the internal economy of the institution. The article on the Instruction of the Deaf and Dumb in the 'North American Review' (No. 83) is understood to have been written by Mr. Barnard, one of the teachers of the New York institution.

The Pennsylvania institution was opened at Philadelphia in 1824; it was organized by Mr. Clerc, and placed under the direction of Mr. Lewis Weld, from the Hartford institution, who, in 1830, was recalled to take the charge of that institution, on the resignation of Mr. Gallaudet. Since that time the Pennsylvania institution has been ably conducted by Mr. A. B. Hutton. The trades taught are weaving, shoemaking, and a few branches of carpentry. Mr. Hutton is assisted by six other teachers, two of them being deaf and dumb, and former pupils of the institution. The directors, in their thirteenth report, state that one supernumerary teacher is employed to guard against the inconveniences which result from the occasional loss of experienced teachers. The state of Pennsylvania provides for the support of 50 indigent pupils for five years, it also provides the more needy with clothing. Maryland supports 20; New Jersey 6; and a few are received from Virginia and other southern states. A few years ago 20,000 dollars were bequeathed to this institution by the will of Stephen Girard, the founder of Girard College.

The Kentucky asylum is situated at Danville, Mercer county: it was opened in 1824. Mr. J. A. Jacobs is its master; he has one assistant and 25 pupils. A certain number of these are supported by the state of Kentucky. This institution was endowed by an act of congress with a township of land in Florida, but, up to the present time, this endowment has yielded a very trifling revenue. Mr. Jacobs has published a most useful series of practical lessons for the deaf and dumb.

In the state of New York a second institution has existed since 1824 at Canajoharie, Montgomery county. The act of legislature in its favour expired in 1836, and it is expected that the pupils will either be transferred to the New York institution, or to a new institution, to be created farther west in the state. Mr. Dix, the superintendent of common schools, recommends the former plan in his report to the legislature. (See *Appendix to 17th Annual Report, New York institution.*)

In 1829 an institution was commenced at Columbus, Ohio. It is partly supported by funds supplied by the state and partly by the payments of pupils. The principal is the Rev. H. N. Hubbell. There are 50 pupils, who are received between the ages of 10 and 30, and four deaf and dumb teachers, who were all educated at Hartford. The State of Ohio supports 48 pupils.

At Quebec, Lower Canada, there is an institution for the deaf and dumb, under the charge of Mr. M'Donald, who studied the system of instruction under the Hartford institution. There are also institutions at Mexico and Calcutta.

DEAFNESS, the sense of hearing diminished or abolished. Deafness is either congenital or acquired. When congenital, it arises from an original malformation of the ear, and is then always accompanied with dumbness. When acquired, it arises from a variety of diseases affecting dif-

ferent parts of the complex apparatus connected with the sense of hearing. Some parts of this apparatus are placed beyond the reach of examination, and the function of other parts is but imperfectly known; so that it is often difficult to ascertain the exact seat of the disease; still more difficult to ascertain the exact nature of the disease, and even when this is discovered, more difficult than all to apply an effectual remedy. Hence the study and treatment of deafness are attended with peculiar difficulties; yet the subject has by no means engaged such a share of the attention of the scientific surgeon and physician as its importance deserves.

Deafness may arise from disease of the organ of hearing, or from disease of the brain. The organ of hearing consists of two parts, that destined to collect and transmit sound to the auditory nerve, and that composed essentially of a peculiar arrangement of the sentient extremity of the auditory nerve destined to receive sound and to transmit the impressions to the brain.

That part of the apparatus whose office it is to collect sound is termed the auricle, or the external ear—the ear commonly so called. From the auricle proceeds a narrow winding passage, termed the external auditory passage (*meatus auditorius externus*), which is closed at its farthest extremity by a membrane called the *membrana tympani*, or the drum of the ear. Beyond the *membrana tympani* is the cavity of the tympanum, which is a chamber of air, containing a curious and complex apparatus, put in motion by the vibrations of the air that produce sound. These vibrations are communicated to the internal apparatus by the *membrana tympani*, or drum of the ear, and, variously modified by that apparatus, and communicated to the air in the chamber of the tympanum, are conveyed to the internal organ, or the ear properly so called. Besides all this there is the passage called the Eustachian tube, which leads from the throat to the cavity of the tympanum. All these parts of the ear are subject to various diseases, any one of which is capable of impairing in a greater or less degree the sense of hearing, or of producing deafness.

Any considerable malformation of the auricle, or external ear, whose office it is to collect the vibrations of the air that produce sound, is found to occasion a greater or less degree of deafness. But the external auditory passage is lined by a vascular and highly sentient membrane, studded with organs of secretion, by which are elaborated the cerumen, or wax, with which the passage is kept in a state of moisture, and by which it is defended from the entrance of external bodies. A certain quantity and a certain quality of this secretion are indispensable to a sound condition of the function of hearing. If the secretion be diminished or suppressed, the hearing becomes extremely imperfect; if it be increased and thickened, the hearing may become altogether abolished. The quantity and quality of this secretion may be changed, in either of these modes, by many diseases; by inflammation, for example, induced by the application of cold and other causes. Accordingly, a vitiated state of the secretion of the wax, which may be accumulated in such a degree as completely to block up the passage, and so to prevent the transmission of sound to the internal ear, is among one of the most common causes of deafness. But inflammation may pass into ulceration; purulent matter may form, collect, and completely obstruct the transmission of sound. Moreover, morbid growths, as polypi, may spring from the lining membrane of the meatus, and plug up the passage. In these different modes there may be a complete obliteration of the auditory passage. This obliteration of the auditory passage is ordinarily attended with the total abolition of the sense of hearing; yet cases are on record in which the canal has been reduced to less than a line in diameter, and in which its walls at different points have even touched, without a great degree of deafness having resulted. In these cases, instead of deafness, there has been a constant noise or buzzing in the ear. Occasionally, though very rarely, there is the opposite state of the auditory passage; it is preternaturally enlarged; in one case it was so much enlarged, that the ring-finger could easily penetrate to the bottom of the canal. Deafness equally resulted from this enlargement of the auditory passage as from its obliteration.

The diseases of the auditory passage may be communicated to the *membrana tympani*, which may be inflamed, thickened, ulcerated, and rendered wholly incapable of performing the office of transmitting sound. It has been observed to acquire a thickness as great as that of the sclero-

tic coat of the eye, by a successive deposition of adventitious membranous layers. It is then of a yellowish colour, and quite opaque. Deafness often coincides with this altered condition of the *membrana tympani*; but it is doubtful whether, if this be the sole affection, it be capable of abolishing the sense of hearing.

The membrane which lines the chamber of the tympanum may partake of the diseases of the parts of the auditory apparatus which are external to it, or it may itself be the primary seat of disease. It may become inflamed and thickened, in consequence of which the capacity of the chamber for containing air must be proportionally diminished. The fluid commonly secreted by its membrane may be increased in quantity and vitiated in quality, and this increased and vitiated liquid may occasion deafness by the exclusion of air from the chamber. Such an altered secretion occurs chiefly in children and young persons whose mucous secretions in general are easily deranged. This accumulation may take place without any pain in the ear, without any discharge of fluid from the ear, and without any appreciable lesion of the auditory passage. It may be suspected to be the cause of deafness when the sense of hearing varies materially at different periods of the day; when the deafness is greatest in the morning, and is suddenly and manifestly increased by a damp day, or by exposure to a cold and humid atmosphere. There may also be an accumulation of pus or of blood in the chamber of the tympanum. Pus may be suspected to be accumulated in the tympanum when deafness follows severe pain in the internal ear, attended with other signs of inflammation; and when inflammation and ulceration of the auditory passage are either absent, or exist only in a slight degree. Blood may be suspected to be contained in the chamber when deafness follows a severe blow on the head in the neighbourhood of the ear; or a fall, or any cause by which a preternatural quantity of blood is determined to the head. Whether the cavity of the tympanum be obliterated by an increased secretion of the fluid which moistens its walls, or by an accumulation of pus, or of blood, the effused matter is often spontaneously removed by absorption, and the sense of hearing gradually returns as the process of absorption goes on.

One of the conditions essential to the sense of hearing is a free passage of air to the chamber of the tympanum through the Eustachian tube. But the diameter of this tube may be diminished or wholly obliterated by an accumulation of the mucus which moistens its internal surface, by the thickening of its lining membrane, and by the adhesion of this membrane at different points. The entrance of air into the Eustachian tube may also be obstructed by various diseases of the throat, as inflammation attacking the soft palate and the tonsils, the consequent enlargement of the tonsils, which may cover and completely close the opening of the Eustachian tube. The inflammation may also spread from the throat into the Eustachian tube; hence the pain in the ear and the deafness which so often accompany severe sore throat.

The internal ear, or that part of the auditory apparatus in which the impression of sound is received, the true and proper ear, is, without doubt, subject to its own diseases; and it is probable that a very slight change in this delicate structure is sufficient to occasion deafness. But this organ is placed so far beyond the reach of examination, and the function of its different parts is so little understood, that its morbid changes, as the causes of deafness, are alike obscure during life, and difficult to be appreciated by inspection after death. The same is true of the diseases of the nerve which transmits the impression from the internal organ of hearing to the brain, and of the diseases of the brain itself. We know that it is indispensable to the sense of hearing that this part of the auditory nerve be sound, and that that portion of the brain with which the auditory nerve is in immediate communication be sound; we know that the auditory nerve and the brain are both subject to numerous diseases which impair or abolish their functions. The substance of the nerve may be diseased, or a tumour may press upon it in some part of its course to the brain; the brain may be diseased,—inflamed, softened, hardened, oppressed by the effusion of water, lymph, pus, blood, or by the growth of tumours in its substance, occasioning general diseases, the most severe to which the body is subject, as phrenitis, hydrocephalus, epilepsy, apoplexy, &c. Among the local morbid phenomena produced by these diseases, deafness is

always one. Often also this malady immediately follows repelled cutaneous eruptions and retrocedent gout, and it is the frequent concomitant of fever. In all these cases deafness is the consequence either of disease of the brain, or of disordered secretions of the auditory apparatus, or of both conjoined; and the hearing always returns as these diseases diminish and disappear.

When deafness arises from inflammation of the auditory passage, the deafness can be cured only by the removal of the inflammation, which must be treated according to the principles proper for the treatment of inflammation in any other part of the body. When deafness results from a disordered action of the follicles which secrete the wax, it is often removed by introducing into the auditory passage, night and morning, a dossil of cotton, containing some stimulating substance, as camphor, ammonia, or alcohol, suspended in almond-oil. When the auditory passage is loaded with hardened wax, the ear should be syringed night and morning with warm milk and water, or soap and water. When polypi grow from the lining membrane of the passage, they must be removed by a surgical operation, and the proper precautions taken to prevent, or the proper remedies employed to remove, inflammation. When there flows from the passage an acrid or fetid discharge, the ear should be cautiously syringed night and morning, and counter-irritation kept up by repeated blisters behind the ear, or by a perpetual blister, caused by daily dressing the vesicated surface with unguentum lyttæ. When the deafness arises from a diminished secretion of wax, good effects have often been experienced by the employment of galvanism, which is found not only to occasion a grateful warmth in the meatus, but also considerably to augment the secretion of wax. When deafness arises from inflammation of the membrane which lines the chamber of the tympanum, and from the consequent thickening of the membrane, or the effusion of fluid into the cavity, the most effectual remedies are blisters behind the ears and active purgative medicines. When closure of the Eustachian tube is the cause of deafness, the imperfection of hearing is often immediately removed by perforating the membrana tympani, this operation immediately establishing a free communication of air to and from the tympanum. When deafness is the consequence of disease of the auditory nerve, or of the brain, the nature of the nervous or cerebral affection must be discriminated and ascertained before any remedy can be applied with the slightest chance of success; and even when this is accomplished, it is too often only to satisfy us that the disease is beyond the reach of art.

DEAL, a borough, market-town, and parish, in the hundreds of Cornilo and Bewsborough, in the county of Kent, and a member of the town and port of Sandwich as a Cinque Port. It is situated close to the sea, on a bold open beach, between the north and south Forelands, eighteen miles south-east from Canterbury, and seventy-two E. S. E. from London. The number of inhabitants in 1831 was 7268, who live for the most part in the three streets lying parallel to the beach, which, in distinction from the middle and upper parts, are called Lower Deal. By a decree of Henry

III., in 1229, and by letters patent of the sixteenth year of Henry IV., the town is shown to have been at that time annexed to the Cinque Ports. A charter was granted by the 11th of William III. constituting it a borough, with a corporation, consisting of a mayor, twelve jurats, 24 common council men, a town clerk, and recorder. On the south side is a strong castle, erected in 1539 by Henry VIII., with a moat and a drawbridge. There is no harbour, but the fine roadstead called the Downs, between the shore and the Goodwin Sands, is a usual place of anchorage for vessels of all dimensions, of which, occasionally, four or five hundred are riding windbound, and with safety, except during heavy gales from the north and east, when some put into Ramsgate for greater security. The pilots of Deal have a high character as intrepid and excellent seamen in affording assistance to vessels in distress. The town is paved, lighted, and watched, and contains a custom-house, a naval store-house, a naval and military hospital, and a gaol. The inhabitants are chiefly engaged in boat-building, sail-making, and other pursuits subservient to maritime business. Besides a church and chapel of ease, there are several Dissenting chapels, and a subscription school for ninety poor boys and girls. Markets are held on Tuesday and Friday, and two small fairs in April and October. Deal is the birth-place of Mrs. Elizabeth Carter, the learned translator of Epictetus. [CINQUE PORTS.] (Brayley and Britton's *Beauties of England*, vol. viii., p. 1018; *Municipal Corporation Report*, part ii., p. 931.)

DEALS (German, *dielen*; Dutch, *deelen*; Danish, *dæler*; Swedish, *tiljar*; French, *planches minces*; Italian, *tavole*; Russian, *doski*.) Deals are boards of fir above 7 inches in width, and of various lengths exceeding 6 feet. If less than 7 inches wide they are called battens, and when under 6 feet long they are called deal-ends. The deals imported into the United Kingdom are brought from Prussia, Sweden, Norway, and Russia in Europe, and from our principal North American colonies. The following statement, compiled with much care by the inspector-general of imports and exports from the entire importation of the year 1834, will show the average dimensions of deals, the produce of various countries, the cubical contents of the great hundred (120), and the rate of duty chargeable upon the importation of each class. The dimensions within which each scale of duty is chargeable, are—

Deals.				per 120.
6 feet and not above 16 feet long, not exceeding 3½ inches thick,	16	21	3½	£19.
" " " " " "	16	21	3½	22.
" " " " " "	21	45	3½	44.
Above 45 ft. in length, or above 3½ in. thick, the load of 50 cubic feet, and further, the 120				£2 10. 6 0.

If of the growth of British possessions in America—

Deals.				per 120.	From Europe.	From American Colonies.
6 ft. and not above 16 ft. in length, not exceeding 3½ in. thick,	16	21	3½	£2 0		
" " " " " "	16	21	3½	2		
exceeding 21 ft. in length, not exceeding 4			4	5		
" 21 " " and exceeding 4			4	10		
Deal-ends.						
Under 6 ft. long, and not exceeding 3½ in. thick, the 120,				£6		
" 6 " and exceeding 3½ " " "				12		1 10

The effect of this method of charging duties, viz., to exact fixed rates upon all deals within given dimensions, has been to interfere greatly with the natural course of trade. When the duty was charged at a fixed rate per great hundred without reference to dimensions, and when that duty was on a moderate scale, it was the practice in the wood-producing countries to cut deals of those dimensions which would produce the greatest cubical quantity of sound wood from each tree, and it then rarely happened that deals were longer than 12 feet, but when the duty was greatly increased, and it was charged according to their dimensions in classes with varying intervals, as shown in the foregoing scale, it became an object to introduce as much wood as possible at each specific rate of charge, and without much regard to economy in cutting. This will be at once apparent when it is seen that under the present scale of duty, a deal brought from Europe 12 feet long and 11 inches wide, pays a duty equivalent to 57s. 6d. per load of 50 cubic feet, while a deal of the same length, but 2 inches narrower, pays at the rate of 70s. 4d. per load; and on one of 16 feet long and 11 inches wide, the charge is equal to only 43s. 2d. per load. It will be equally apparent that with a rate of duty forming a large per-centage upon the first cost of the article, no person will import any deals much short of each of the maximum dimensions admissible at each rate of duty, but will sacrifice a part of the material when necessary, in order to escape a higher rate of charge; by this means the cost is necessarily enhanced to the consumer. The same motive does not operate with respect to the lower taxed deals of the English colonies, nearly the whole of which are accordingly brought of such dimensions that the duty amounts to one-third more upon the cubical contents than it would amount to if the importers availed themselves of the provisions of the law in the way adopted by the importers of European deals. It will be seen that the duty charged upon the deals of Sweden, and still more upon those of Norway, is, by the working of the system, much higher than upon the shipments from Russia and Prussia; this arises partly from the different sizes to which the trees grow in the respective countries, and partly from the difficulty experienced in Sweden and Norway in conveying the trees after they are cut down rapid or narrow rivers to the places of manufacture. In France, where the duties on timber are low, deals are imported of all sizes suited to the convenience of the producers, and consequently the price is lower to the consumer; besides which, the quality of the wood is in some instances better, because thinner deals than are brought to England may be cut from the best part of the tree nearest to the sap, and these are now virtually excluded from our markets. The deals of North America are inferior in strength and durability to those brought from the north of Europe, and to these the preference is usually given for the flooring of houses and other purposes where durability is of importance. In building smaller houses, where cheapness is the principal consideration, Canadian deals are used. For small articles, such as mouldings, picture-frames, hat-boxes, musical instruments, as well as for many of the internal fittings of houses, and other purposes which call for the employment of wood that can be easily worked, Canada deals are preferred.

Great fault has been found with the present scale of timber duties, because encouragement is given by it to the importation of deals over that afforded to the introduction of the timber out of which the deals are cut, but among all the evils attending the present system of duties, this one is

not to be reckoned, inasmuch as the true interest of the consumer is best consulted by giving that greater encouragement to the importation of deals. In its natural form the timber could not be brought in a state fit for sawing. If the deal be not cut from the log as quickly as possible after this is felled, the grain of the wood will open, and it will be full of splits, or what is called shakey, and if afterwards cut into thin boards they will be fit for nothing. The splits or fissures here noticed are not of equal detriment to timber in the log, which is sawn into large scantlings to be used for beams, rafters, and quartering: from the moment the saw has divided the log into thinner pieces the tendency to split is at an end.

The quantity of deals and deal-ends imported from the north of Europe and from the British American colonies respectively in each of the last 10 years, has been as follows:—

	From Europe. Great hundreds.	From America. Great hundreds.	Total. Great hundreds.
1827	37,910	12,084	49,994
1828	33,892	15,730	49,622
1829	33,332	18,256	51,588
1830	30,551	19,653	50,204
1831	32,848	22,067	54,915
1832	25,210	26,053	51,263
1833	24,823	30,975	55,798
1834	33,105	34,000	67,105
1835	27,492	34,239	61,731
1836	31,865	37,388	69,253

The demand for timber in the United States of America has of late much increased, owing to increasing population on the one hand, and the progressive diminution of the forests in the settled states on the other. Under these circumstances measures are in progress on the part of the United States' government which will encourage the transmission of timber in all its forms across the river St. Lawrence to a degree which may materially interfere with the power of Canada to supply this country on the same scale as heretofore.

DEAN, French *Doyen*, and in Latin *Decanus*, a word which on a first view would be thought to be allied to DEACON, but which has probably a different origin. Etymologists seem not to be agreed concerning the etymon; but the most usual origin assigned to it is the word *decem*, ten, as if a dean were a person who presided over collective bodies of men or things, in number *ten*. This we regard as very uncertain.

Dean, however, is a term of ecclesiastical presidency. In Scotland it is used for the head of lay communities, but in England we believe it is exclusively confined to promotions or presidencies spiritual.

In England there are three classes of ecclesiastical presidencies to which the title dean belongs.

1. *Deans rural*.—It will be seen that in all the books which treat of the ecclesiastical divisions of the country, the dioceses are divided into archdeaconries, and the archdeaconries into deaneries, below which there is no other subdivision till we come to parishes, the minutest of the proper ecclesiastical divisions of the country. The whole country is thus divided, with the exception of certain districts of no great extent, which claim to be exempt jurisdictions.

Those who contend for the derivation of the word dean, whence deanery, from *decem*, suppose that originally there were *ten* churches or parishes forming each of these deaneries. This is a very obscure point, and it is equally uncertain at what time this distribution of the dioceses was made. It appears, however, that there were deaneries before the Norman Conquest.

In each of these deaneries there was a clergyman who was dean; he was usually a beneficed clergyman within the deanery. His duties were to exercise a superintendency over the clergy, to preside at their assemblies, and to be the medium of their communication with their spiritual superiors. He had his public seal. He appears also to have discharged those duties which are now performed by clergymen called surrogates.

By degrees this office in the English church fell into disuse. The history or the reason of its decline is not very well known, for the advantage of having such an officer, especially where the archdeaconries were extensive, must have been always evident. The office, however, did by degrees disappear in one diocese after another, till it became

totally lost. There was a dean of Chalke, in the diocese of Salisbury, as late as the reign of Charles the Second; and a dean of Doncaster, in the diocese of York, in the reigns of George the First and Second.

Attempts have been made to revive it. Berkeley, bishop of Cloyne, tried to establish the office again in Ireland; and soon after the late Dr. Burgess was made bishop of Salisbury, he did actually revive the office in that diocese, appointing Mr. Dansey, the rector of Donhead St. Andrew, rural dean of Chalke: this was in 1825. The Report of the Ecclesiastical Commissioners, 1835, under the head Territory, recommends that each parish shall be assigned to a deanery, and each deanery to an archdeaconry.

Whoever desires to see more concerning the constitution and office of the rural dean will be amply gratified by referring to a work, in two volumes quarto, entitled '*Hæc Decanice Rurales*, being an attempt to illustrate by a series of notes and extracts the name and title, the origin, appointment, and functions, personal and capitular, of Rural Deans, by William Dansey, &c., 1835.

The office existed in other parts of christendom.

2. *Dean in a Cathedral Church*. [See CANON.] The canons who formed the bishop's council were presided over by a dean; this has been the case from the remotest times. *Decanus et Capitulum* is the form in which all the acts of such communities run.

Antiently the deans were elected by the chapters; but here, as in other points, the royal power has encroached on the privileges of the church. Now the form is for the crown to issue a *congé d'elire*, naming the person whom the chapter is to choose, in the bishoprics of antient foundation; while, in the bishoprics founded by Henry the Eighth, the king names the dean by his letters patent merely. In the former case the bishop is called in to confirm the election, and he issues his mandate for the installation of the person elected.

3. *Deans in Peculiars*.—There are in England certain ecclesiastical promotions, in which the person holding them is called by the name of dean, and they seem to have all had antiently, as some of them have now, capitular bodies connected with them, and in all there is something peculiar in their reference to their spiritual superiors, and in the jurisdiction exercised by them. We cannot descend into the particular character of each of these officers, and shall content ourselves with naming the principal of them: the dean of Westminster; the dean of the chapel of St. George, of Windsor; the dean of Christ Church, Oxford; the dean of the Arches; the dean of the King's Chapel; the dean of Battel; the dean of Bocking; the dean of Middleham, &c. If the history of these foundations were traced to their origin, it would be seen that they were ecclesiastical establishments, mostly of royal foundation, possessing peculiar privileges and a peculiar jurisdiction, which escaped dissolution when the framework of the ecclesiastical institutions of England underwent some alteration at the time of the Reformation.

DEATH-WATCH. Every one has heard of the death-watch, and knows of the superstitious notion of the vulgar, that in whatever house its drum is heard, one of the family will die before the end of the year. These terrors, in particular instances, when they lay hold of weak minds, especially of sick or hypochondriac persons, may cause the event that is supposed to be prognosticated. A small degree of entomological knowledge, however, would relieve them from their fears, and teach them that this heart-sickening tick is caused by a small beetle giving a call to its companion.

Authors were formerly not agreed concerning the insect from which this sound of terror proceeded, some attributing it to a kind of wood-louse, and others to a spider; the earliest scientific account of it is probably that by Mr. Benjamin Allen, written in 1695, and published in the *Philosophical Transactions*, vol. xx., p. 376, where the writer calls it *Scarabæus galeatus pulsator*: followed, vol. xxii., p. 832, by another account from the celebrated Dr. William Derham, dated Upminster, July 21, 1701. Swammerdam (*Bibl. Nat.*, edit. Hill, i., 125,) and Shaw (*Nat. Misc.*, iii., 104,) have also written upon this insect. It is a received opinion now, adopted upon satisfactory evidence, that the sound called the death-watch is produced by certain beetles belonging to the timber-boring genus *Anobium*. Latreille observed *Anobium striatum* to produce the sound in question; but the species whose proceedings have been most

noticed by British observers is *Anobium tessellatum*. When spring is far advanced, these insects commence their ticking, which, as already mentioned, is only a call to each other, to which, if no answer be returned, the animal repeats it in another place. It is thus produced: raising itself upon its hind legs, with the body somewhat inclined, it beats its head with great force and agility upon the plane of position; and its strokes are so powerful as to make a considerable impression if they fall upon any substance softer than wood. The general number of distinct strokes in succession is from seven to nine or eleven. They follow each other quickly, and are repeated at uncertain intervals. In old houses, where these insects abound, they may be heard in warm weather during the whole day. The noise exactly resembles that produced by tapping moderately with the nail upon the table; and when familiarized, the insect will answer very readily the tap of the nail. (Brand's *Popular Antiq.*; Kirby and Spence's *Introd. to Entomology*, edit. 1828, i. 36; ii. 382; Wallis's *Hist. Northumb.*, i. 367.) The superstition that the clicking of this insect is a death-omen is mentioned by Baxter in his '*World of Spirits*,' p. 203.

DEBENTURE (Latin, debentur, from debeo, to owe), formerly written debentur, is a kind of certificate used at the Custom House, which entitles a merchant exporting goods upon which a drawback or bounty is allowed to receive payment. (As to drawback or bounty see 3 & 4 William IV., cap. 58, sec. 86, 87.)

The word has been used in some acts of parliament to denote a bond or bill, by which the government is charged to pay a creditor or his assigns the money due on auditing his account. Debentures were used to secure the arrears of pay to the soldiery during the Commonwealth, and are mentioned in the Act of Oblivion, 12 Car. II., cap. 8. They are in use now in the receipt of Exchequer and Board of Ordnance, and it is believed in the king's household. (Cowel's *Interpreter*; M'Culloch's *Commercial Dict.*)

DEBRECZIN, or **DEBRECZYN**, a royal free town in the western part of Upper Hungary, is the capital of the county of Bihar, and the largest town in the kingdom, Pesth only excepted. It lies in 47° 32' N. lat., and 21° 36' E. long., in the centre of an extensive sandy plain, which stretches from this neighbourhood through the counties of Bihar and Szabolts, and is known by the name of the '*Debreczyne Heide*.' The southern part of this great plain in the vicinity of Debreczin has been brought into a state of high cultivation, and produces abundant crops of wheat, buckwheat, millet, and water-melons: it also affords pasturage for cattle and sheep. The town is open, and has a rustic appearance; for the houses, which are about 4000 in number, seldom exceed one story in height, and are as humble in their exterior as common cottages. Including the three suburbs, from which it is separated by a slight pallisade, Debreczin contained, in 1816, 38,962 inhabitants, and now has about 45,370, of whom about 43,800 are of the Protestant church. The country being destitute of stone, the streets are unpaved, and the foot-passenger has consequently to wade either through mud or sand, according to the season of the year, with the aid of a few planks, laid down for crossing the streets. It is the seat of civil administration (*Distrikt-Gerichts-Tafel*) not only for the county, but for the province 'on this side of the Theiss,' and is the occasional place of meeting for the provincial assemblies of the county. Debreczin has several handsome buildings, among which are the town-hall, the Protestant and Roman Catholic churches, the Franciscan and Piarist monasteries, and the handsome Protestant Collegium, which is conducted by six professors, and attended by 600 students, and to which a small church and a library of 20,000 volumes are attached. There is also a Roman Catholic gymnasium, a school of design for mechanics, &c., an orphan asylum, three dispensaries, three hospitals, and a house of correction. Nor must we omit to notice Councillor Fay's fine collection of paintings and engravings. Independently of agricultural pursuits, the inhabitants derive their subsistence from numerous manufactures, principally of coarse woollens, sheepskins, pottery, leather, saltpetre, and soap. The manufacture of tobacco-pipes amounts to about eleven millions per annum, and employs two classes of artificers, one for turning the mouth-pieces out of horn, and the other for fashioning the heads out of red or black clay. Debreczin manufactures also knives and other cutlery, combs, buttons, pearl necklaces, &c. Its central position between Transylvania

and the north and west of Hungary affords it a ready vent for its various products: this is also facilitated by four periodical fairs, which are held in wooden booths outside the town, and are the resort of buyers and sellers from all parts of the kingdom. They are a great market also for the linens and other fabrics of Germany. Debreczin is noted for the excellence of the bread, as well as the immense loaves, made by its female bakers. It suffers greatly from want of water in summer. The yearly income and expenditure is about 137,000*l.* (1,500,000 guldens.)

DEBT, ACTION OF, lies for the recovery of a sum certain, or capable of being ascertained, due upon bond, specialty, or simple contract, or upon the judgment of a foreign or colonial court. It may also be maintained against a gaoler for the escape of a prisoner in execution, or upon a statute by the party grieved, or by common informer. Previous to 3 & 4 William IV., cap. 42, sec. 13, the defendant in an action of debt upon a simple contract (except for rent) was allowed to wage his law, for which reason the action of indebitatus assumpsit [ASSUMPSIT] was frequently preferred; but now the action of debt is the better remedy in such cases, the judgment being final in the first instance. The action of debt will not lie for money due by instalments till all the days are past, unless the payment be secured by a penalty, or the amount to be paid on each day be specified; nor can debt be supported against an executor or administrator upon a simple contract of his testator or intestate, because as they are presumed to be ignorant of his contract they cannot wage their law: though this distinction is still observed, it has been judicially declared not to be founded in good sense. Where, however, the deceased would not have been allowed to wage his law, as in actions in the Court of Exchequer, in London (by the custom), &c., debt is maintainable against executors and administrators. (Selw. *Nisi Prius*; Saunders's *Reports*.) [**DAMAGES**; **PLEADING**.]

DEBT, NATIONAL. [**NATIONAL DEBT**.]

DECAGON, a figure of ten sides; but the term is most commonly applied to an equilateral and equiangular decagon, or a *regular* decagon.

The side of a regular decagon inscribed in a circle is $\cdot 6180340$ of the radius; and of that about a circle $\cdot 6498394$ of the radius. Similarly, the radii of the circles inscribed in and circumscribed about a decagon are $1\cdot 5388418$ and $1\cdot 6180340$ of the side. The area of a decagon is $2\cdot 938927$ of the square on the radius of the circumscribed circle, or $7\cdot 694209$ of the square on the side.

DECANTATION, an operation often resorted to both in common life and in chemical operations; it is the action of pouring off the clear portion of a fluid from that which contains suspended impurities, or from the impurities themselves when they have perfectly subsided. Sometimes this method is employed in order to avoid the use of filters; and there are cases in which it is preferable, as when the solution is so acid or alkaline that it would destroy paper or linen.

DECAPITATION, beheading: a punishment, in all probability, of very antient date, and certainly known among the Greeks and Romans. Xenophon, at the close of the second book of *Cyrus's Expedition*, says, that losing the head was looked upon as the most honourable death. The decollation, as it is called, of St. John Baptist shows the existence of this punishment among the Jews under the Roman government of Judæa. Suetonius (*Calig. c. 32*) tells us that Caligula kept a soldier, an artist in beheading, who decapitated prisoners in his presence, fetched indiscriminately for that purpose from the gaols. Hoveden and Florence of Worcester agree that Earl Waltheof, who was beheaded by William the Conqueror in 1075, was the first Englishman who suffered that punishment.

The Messrs. Lysons speak of beheading as an ordinary punishment, in old time, of felons, in Cheshire. They say, 'An antient MS. relating to the earls of Chester informs us that the serjeants or bailiffs of the earls had power to behead any malefactor or thief who was apprehended in the fact, or against whom guilt was proved by sufficient witness, or confession before four inhabitants of the four neighbouring towns.' Then follows an account of the presenting of several heads of felons at the Castle of Chester by the earl's serjeants; and it appears that the beheading of malefactors was the usual mode of execution in this county; for in a roll of 3 Edward II. it is called the custom of Cheshire. In France criminals capitally convicted are be-

headed, not hanged. (Lysons' *Chesh.*, p. 299, from the Harl. MS. 2009, fol. 34, b.)

From another part of their work it appears that criminals convicted of felony were punished in the same manner in the barony of Malpas; and that this power was even exercised by the several possessors of the moiety and fourth parts of that barony. In the 6 Edward II., David Bulkeley, serjeant of the peace to Richard Sutton, presented the heads of two felons executed for burglary, and Hugh Cholmondeley, serjeant of the peace to John de St. Pierre, presented the head of Thomas Burness, executed for theft, and had his fee called the *radying* fee. (Ibid., pp. 677, 678, from the Harleian MS. 2079, fol. 124 and 131.) The foresters of Hardwick, in Yorkshire, had this punishment allotted to them for theft.

At a somewhat later period decapitation became a punishment more especially appropriated to the higher orders of society. Henry VIII. beheaded two of his queens. Elizabeth beheaded a sister sovereign. The High Court of Justice beheaded Charles I. In 1644, Archbishop Laud was condemned by the two houses of parliament to suffer death by hanging; and the only favour granted to him upon supplication, after delay and with reluctance, was, that his sentence should be changed to beheading. Losing the head still continues to be considered the most honourable mode of receiving capital punishment in England; but there has been no recent instance of its being inflicted. The last was in the case of the rebel lords of 1745.

DECA'PODA. [CRUSTACEA, vol. viii., p. 197.]

DECCAN (DACSHINA, THE SOUTH) was antiently understood to comprehend the whole of the peninsula of India, situated to the south of the river Nerbudda and the southern boundaries of Bengal and Bahar, and included nearly one-half of the territory generally known under the name of the Mogul empire. The Mohammedan invaders being unable, after several centuries, to fix their possessions south of the Kistna, the name Deccan came to denote the countries lying between the Nerbudda and the Kistna, and the latter river is still understood to form its southern boundary. The Deccan therefore comprehends the following divisions: Candeish, Gundwana, Orissa, Berar, the Northern Circars, Beeder, Aurungabad, Hyderabad, and Bejapore.

The first Mohammedan invasion of the Deccan occurred at the close of the thirteenth century, in the reign of Feroze. Alla, the nephew of that prince, then marched to Deoghur, and exacted heavy contributions as the price of his return. Alla, having succeeded Feroze, again invaded the Deccan in 1304, overran several of the districts, which he divided among his Omrahs, and laid siege to Deoghur, and compelled the rajah to submit, and acknowledge that he held his territory as a dependency. In 1310 Caffer, one of Alla's generals, was again sent into the Deccan, and penetrated to the Carnatic, which kingdom he ravaged, taking its rajah prisoner, and collecting an immense amount of treasure. Upon the accession of Mohammed the Third, that prince sent a large army into the Deccan, and entirely reduced the Carnatic to his dominion. In a few years thereafter he not only transferred the seat of his government to Deoghur, the name of which he changed to Dowlatabad, but he forcibly removed thither the entire inhabitants of Delhi, leaving the antient capital desolate. Upon the death of Mohammed, which took place amidst rebellions and insurrections in all parts of his dominions, the rebel chiefs agreed to elect a sovereign, and chose an Afghaun named Ismael for king. When this prince had reigned only a few years, he resigned his throne in favour of one of his generals, Hussun, who had originally been an Afghaun slave, and who, on mounting the throne, assumed the title of Sultan Alla ad Dien Hussun Kongoh Bhaminee, and was the founder of the Bhaminee dynasty. During his reign, which lasted eleven years, Alla reduced to his sway all the districts of the Deccan which had at any time acknowledged the sovereignty of the emperors of Delhi, and was the first independent sovereign of the Deccan. His reign was marked by wisdom and moderation: he died in 1357, and was succeeded in turn by twelve sultans of the Bhaminee dynasty, the last of whom, Mohammed Shah Bhaminee, died in confinement in 1518. The Deccan after this was divided into five kingdoms, viz. Bejapore, Golconda, Berar, Ahmednuggur, and Beeder. The sovereigns of these kingdoms were engaged in constant wars with each other. Towards the close of the sixteenth century, the Deccan was invaded by Akbar, and the terri-

tory of Ahmednuggur was subdued, and formed into a province of the Mogul empire. In the reign of the Mogul emperor Shah Jehan, his son, the celebrated Aurengzebe, was appointed to command the army on the southern frontier of the empire, and he was not long without a pretext for invading the Deccan, the sovereigns of which he soon reduced to a state of dependence. When he ascended the throne, this prince made war upon these dependent sovereigns, and reduced the whole under his immediate sway: these operations were not completed until the year 1700. In the subsequent reign of Ferokhsere, Nizam al Mulk was sent as viceroy into the Deccan, and soon became its virtual sovereign. The whole country was in fact, from 1717, independent of the Mogul empire, and so continued until the year 1818, when a great part of the

Deccan came under the dominion of the English. The Northern Circars were indeed acquired from the Nizam in November, 1766, but it was not until 1818 that the districts known as the British Deccan came immediately into our possession. Candeish was then acquired from Mulhar Rao Holkar; Poona, the Concan, and the Southern Mahratta country was conquered from the Peishwah; and some lands in the Southern Concan were acquired from the rajah of Sawuntwarree. The remaining parts of the Deccan are in possession of the rajah of Berar, the Nizam, and the rajah of Sattara. The territory acquired by the English in 1818 has been divided into four collectorates, viz., Poona, Ahmednuggur, Darwar, and Candeish, the state of which in 1827-8 has been thus given by Colonel Sykes, statistical reporter to the government of Bombay.

Collectorates.	Area.	Number of Houses.	Number of Villages.	Number of Inhabitants.	Number of Cultivators.	Begahs of Cultivated Land.	Amount of Land Revenue.	Total Revenue.
	Sq. Miles.						Rs.	Rs.
Poona	8,281	114,887	1,897	530,313	52,668	1,527,372	15,16,323	19,92,000
Ahmednuggur	9,910	136,273	2,465	666,376	41,948	1,468,180	18,15,837	20,33,995
Darwar	9,122	187,222	2,491	838,757	60,701	2,649,598	19,45,323	24,21,516
Candeish	12,527	120,822	2,682	478,457	44,698	1,656,345	16,64,905	19,87,733
	39,840	559,204	9,535	2,533,903	199,925	6,701,495	69,42,388	84,35,244

The Deccan begah is equal to three-fourths of a statute acre, so that the average assessment on the land is equal to 2s. 9½d. per acre, and constitutes more than four-fifths of the total revenue of the collectorates. All lands are comprised within the limits of some village, each of which has a constitution for its internal government, consisting of a patel or chief, assisted by a chaugula, the kulkami, or village accountant, and other officers called baraballi, the number of the latter depending on the population of the village. A few villages constitute a naikwari, over which an officer presides with the title of naik. Eighty-four villages constitute a pergunnah, or county. Over this number there was formerly placed a desmukh, or governor, assisted by a district accountant and registrar. The lands in this part of India were held under an hereditary tenure; the land-tax is said to have been fixed, but the former governments assumed the power of levying supplementary assessments. Many of the Maharatta families who were in possession of these hereditary estates are extinct, and their lands are now held by a class called upari, a word which signifies strangers, and who are rated each year to the land-tax by mutual agreement between them and the government, the rates being usually the same, or nearly so, as the permanent assessment. A third class hold their lands under leases for five, seven, or nine years, at a rent low at first, and increasing every year till the expiration of the lease. This mode is resorted to in order to encourage men to undertake the cultivation of waste land. Two other tenures, those of Jaghire and Inam, are recognized in the Deccan. Lands so held are free from any government tax. Jaghire is the term applied to lands given for personal or military service, and which must be considered in the light of a fief, implying the obligation on the part of the holder to support the government either by personal service or by maintaining troops. In the four collectorates of the Deccan more than 400 villages have been thus granted by the government. Inam, a word signifying a gift or present, is applied to lands granted usually in small portions in return for some personal service, such as playing music or dancing in the temples: the lands thus given seldom exceed a few begahs in extent. In most villages of the Deccan are to be found some Ramosis, who are thieves by birth, and who have lands given to them in Inam, that they may hold themselves responsible for the safety of property in the district where they reside. Various witnesses who were examined before the Committee of the House of Commons in 1832 concurred in stating that the condition of the cultivators and of the inhabitants generally has been much improved since the Deccan came into the possession of the English government.

DECEMBER. This month still retains the original name assigned to it in the Alban, and first Roman calendar adopted according to tradition by Romulus, in both of which it was the tenth, as the name signifies, or last of the year. Our Saxon ancestors called it *Mid-winter-month*, *mid-winter month*, and *zeola* or *yule-month*, from *zehpeol*, a wheel, emblematical of the sun's revolution or return in his annual course.

December was antiently consecrated to Saturn: Alexander ab Alexandro, in his '*Genialium Dierum Libri sex.*' says to Vesta, the daughter of Saturn. In the Alban calendar this month consisted of thirty-five days. Romulus reduced it to thirty; and Numa to twenty-nine days. Julius Cæsar restored the day of which Numa had deprived it; and Augustus added another day, which it still retains. Commodus, who attempted to change the names of several of the months, with the assistance of his flatterers, gave that of Amazonius to this, in honour of his mistress, Martia, whom he delighted to see clothed in the Amazonian habit. (Pitisci, *Lexicon*, i. 633, *in voce*; Court de Gebelin, *Allegories Orientales*; Brand's *Popular Antiq.*, vol. i., p. 364; and Brady's *Clavis Calendaria*, i. 92.)

DECEMVIRI, or Ten Men, the title of various magistrates or functionaries in antient Rome.

1. *Decemviri legibus scribendis*, i. e. ten men for the purpose of making a new code of laws, were certain extraordinary magistrates, or rather a commission of ten men, invested with the power both of framing a new code and administering the republic. In the early times of antient Rome the judicial power belonged to the kings, and, after their expulsion, to the consuls, who did not decide according to written laws, but only according to usages and customs. As such usages and customs were necessarily subject to doubt, and as the consuls were chosen only from the patrician order, the disputes between patricians and plebeians were probably often decided partially in favour of the former; and this would happen more especially in criminal cases, for which no certain law was provided. These circumstances led to the institution of the decemvirs.

After many violent struggles, the senate and the plebeians, B.C. 453, agreed that certain written laws should be framed, to which every citizen, without any distinction, should be subject. A commission of three members was appointed to visit Athens for the purpose of getting a copy of Solon's laws and making themselves acquainted with the institutions of other Greek states. (Liv. iii., 31.) The commissioners having returned at the expiration of two years, the tribunes immediately called for the new code. For this purpose another commission, consisting of ten members, was named by the comitia centuriata. Uncontrolled power, both administrative and judicial, without any appeal, and accompanied with the suspension of all other magisterial offices, including the consuls and tribunes, was conferred on them. The names of the ten commissioners are recorded in Livy (iii. 33) and Dionysius Halicarnassus (*Antiq. of Rom.*, xi., 56). Appius Claudius was the leading member of the ten; he was the soul of the commission, and directed all the business. The decemvirs conducted themselves with great moderation and justice. On the expiration of their year of office, they had framed a body of laws, distributed into ten sections, which were approved by the senate and the comitia, and engraved on ten tables of metal.

As the new laws seemed imperfect in some respects, a new commission was named, at the head of which was the same Appius Claudius (Liv. iii., 35). But the decemvirs now began to behave in a very different manner: they

became true tyrants, and formed a most pernicious oligarchy. They framed, however, several new laws, which were approved by the centuries and engraved on two tables. Though their commission and the year of their office were now at an end, they still would not resign, but continued to hold their power in the year 447 B.C., and to exercise it in a most arbitrary manner. Appius Claudius, by a most unwarrantable decision, declared Virginia, the daughter of Virginius, an officer in the Roman army, a slave, because she had refused to listen to his dishonourable proposals. Virginius, the father, to save his daughter from violation, murdered her in the public place, and, with the bloody knife in his hand, called on the people to take vengeance on their oppressors. Both the citizens resident in Rome and the army united themselves to overthrow the tyrannical power of the decemvirs, who were forced to abdicate, and the ordinary magistrates were re-established. Appius Claudius was put in prison, where he died.

The ten tables of the former and the two of the latter decemvirs together form the laws of the twelve tables.

2. *Decemviri litibus judicandis*, i. e. ten men for the purpose of deciding suits, formed a court of justice under the superintendence of the prætor, which was established about B.C. 287. The establishment of this body was caused by the great increase of suits, which rendered it impossible for the prætor to get through the business of his court. As to the powers of these decemvirs, we have no distinct notices.

3. *Decemviri sacris faciundis*, were an ecclesiastical college, the members of which were elected for life. The care of the Sibylline books belonged to them, and were consulted by them on important occasions.

4. *Decemviri agris dividendis*, were a commission for the temporary purpose of dividing lands among the colonists when a new colony was to be established.

DECHÂLES, CLAUDE FRANÇOIS MILLIET, was born at Chambéry, the capital of Savoy, in 1611. He wrote largely on several branches of mathematical, mechanical, and astronomical science; but the only work by which he is generally known is his edition of Euclid, which was long a favourite text-book in France, and in other parts of the Continent. It was also translated into English; but did not obtain great popularity among our countrymen, whose taste in geometry continued, till recently, to partake strongly of the pure severity of the ancient Greek writers.

Dechâles was, however, an accurate and elegant writer on the subjects which he treated; and there are interspersed through his works many marks of considerable invention, as well as of a happy power of adaptation of the knowledge of his predecessors and contemporaries. Still he was not one of those men who had the power greatly to extend the boundaries of science: it was his province rather to place it in such a light as to facilitate its acquisition by others.

He was appointed professor of mathematics in the College of Clermont, the chair of which he appears to have filled for about four years; and thence he removed to Marseilles, where he taught navigation, military engineering, and the applications of mathematics to practical science. From Marseilles he went to Turin, where he was appointed professor of mathematics in the university; and died in that city in 1678, being sixty-seven years of age.

As a teacher, Dechâles was remarkable for his urbanity, and for the adaptation of his instruction to the previous acquirements of his pupils; and as a man, his probity and amiable spirit gained for him the admiration and love of all with whom he was associated.

The works of Dechâles were published at Lyon in 1690, in four folio volumes, under the title of *Mundus Mathematicus*. A former edition of these was also published in three volumes; but this edition is far less complete than that of 1690.

DECIMAL FRACTIONS. [FRACTIONS, ARITHMETIC.]

DECIMAL NOTATION. [NUMERATION, ARITHMETIC.]

DECIMAL SYSTEM OF WEIGHTS AND MEASURES. [WEIGHTS AND MEASURES.]

DECIUS MUS, a Roman who distinguished himself by many warlike exploits, and received many honours. In a battle against the Latins he voluntarily devoted himself to the *Dii Manes*. He had made an agreement with his colleague, Manlius Torquatus, that the consul whose wing first gave way should devote himself to death. The ceremony of consecration was performed with great solemnity, and having directed the lictors to acquaint the other consul

that he had given himself up for the safety of the army, he rode into the thick of the enemy, and was soon overpowered by a shower of darts, about B.C. 338. His son Decius Mus followed his heroic example in a war against the Gauls, B.C. 295, as well as his grandson in the war with Pyrrhus, B.C. 280.

DECIUS CAIUS MESSIUS QUINTUS TRAJANUS, the Roman emperor, succeeded Philip, and chiefly distinguished himself for his violent persecution of the Christians. He and his son fell in an expedition against the Goths, about A.D. 251.

[Coin of Decius Trajanus.]

British Museum. Actual Size. Copper. Weight 363½ grains.

DECKER, THOMAS, flourished as a dramatic author in the reign of James I., though the precise time of his birth and death, like those of many of his contemporaries, are uncertain. He is celebrated for a quarrel with Ben Jonson, who satirized him under the name of Crispinus in his 'Poetaster'; Decker returned the compliment by writing his 'Satyromastix,' wherein Jonson is attacked under the name of 'Young Horace.' The author of the 'Biographia Dramatica' says that he became more famous from this quarrel than from any merit of his own. Later critics have, however, been more favourable to Decker, and Mr. Hazlitt pronounced the character of Friscobaldo in the 'Honest Whore' to be perfect in its way, as a picture of a broken-hearted father with a sneer on his lips and a tear-drop in his eye. This comedy is written with great power and with a high moral feeling. Decker composed many plays in union with other dramatists; and the collected works of Webster, Massinger, and Ford exhibit specimens of his partnership-writing, though it is hard to assign the respective portions of productions of this sort to their right authors. Mr. Gifford has attributed all the gross indecencies of Massinger's 'Virgin Martyr' to the hand of Decker; but many have considered this slur on the morality of the latter to be unjust. Of the plays written solely by Decker the 'Honest Whore' is the most celebrated, and is printed in Dodsley's Collection. Besides his dramatic works, his 'Gull's Hornbook' has become better known by an edition recently published.

DECKER, JEREMIAS DE, one of the most esteemed Dutch poets of the seventeenth century, was born at Dordrecht, in 1610, as is generally supposed, but certainly between the years 1608 and 1612. His father Abraham de Decker, who had embraced the reformed religion, was, although of good family, in very moderate circumstances, first as a tradesman, afterwards as public broker. Attached to reading himself, particularly the works of all the best historians, he endeavoured to cultivate a similar taste in his children, and was rewarded by finding his son Jeremias display considerable talents and application at a very early age. Aided merely by such instruction as his father could give him and his own natural aptitude for learning, which was seconded by an excellent memory, young De Decker made so great proficiency that while yet a lad he made himself master of the Latin, Italian, French, and English languages, notwithstanding he was even then obliged to assist his father in his business. At no time of his life in fact can literature be said to have been his occupation, yet that and poetical composition continued to the last the solace of an existence passed in so uniform a tenor as to afford no materials for biography beyond what immediately relates to his writings.

His earliest essays in poetry consisted of paraphrases from Jeremiah, &c., and of translations and imitations from Horace, Prudentius, Buchanan, to which may be added his 'Good Friday,' a collection of pieces breathing the most pure devotional feeling. Indeed a strong vein of unaffected religious sentiment runs through all his compositions, for, as with our own Cowper, religion was with

De Decker an abiding influence. Nowhere does sincerity of piety or the warmth of the domestic affections display itself more touchingly than in his poem on the death of his father, in that of consolatory exhortation to his widowed mother, and in another piece on his brother David, who died at Batavia. Even his *Punttdichten* are many of them of a religious, all of a moral tendency, being for the most part so many condensed ethic lessons and reflections rather than epigrams, except as to the ingenious turn and point, which frequently render them highly impressive, although their subjects may be familiar truths. The longest of all his productions is his *Lof der Geldzucht*, or 'Praise of Avarice,' a poem in which that vice is satirized in a strain of most amusing irony. It is replete with learning, felicity of illustration, and a playfulness of tone which only serves to render it all the more caustic; no wonder therefore that it has been greatly admired, and has earned for itself a place beside Erasmus's celebrated 'Moriæ Encomium.' This was almost the very last piece he ever wrote, nor did he live to enjoy its reputation, for he died while it was in the press, in November, 1666.

DECLARATION (declaratio), in law, is the statement of his case by the plaintiff in an action at law: in a real action it is properly called a count (narratio). In this, the first of the pleadings in a cause, the plaintiff states the nature and quality of his case, in general more fully than in the writ, but still in strict conformity with the tenor of that instrument, any substantial variance being a ground of objection. (Co. Litt.; Stephen.) [PLEADING.]

DECLINATION. When a star is not in the equator, the angle made by two lines drawn from the spectator's eye, one to the star, the other to the nearest pole, is called its polar distance. The complement of the polar distance, or the angle subtended by the star and the nearest point of the equator, is the declination of the star. It is called north or south according as the star is north or south of the equator. The declination (it is becoming very common to use the polar distance in preference) and the right ascension [ASCENSION, RIGHT] are the usual co ordinates to which a star's place is referred. Confining ourselves here to declination, we must merely remark that the effect of a diminution in declination is to bring the star nearer to the equator, and its time of appearance above the horizon nearer to twelve hours. The length of a star's (or of the sun's) time above the horizon is found as follows:—Multiply together the tangents of the latitude of the place and of the declination of the star. If the answer be greater than unity, the star is too near the north pole to set, or too near the south pole to rise (according as the declination is north or south); if equal to unity, the star grazes the horizon at the north (or south) points, but does not set (or rise); if less than unity, find the angle which has the preceding product for its cosine, convert it into time at the rate of 15° to an hour, and the defect from twelve hours is the half of the duration required, expressed in sidereal time.

DECLINATION OF THE MAGNETIC NEEDLE (or Variation of the Magnetic Needle), is the angle which the horizontal needle makes with the geographical meridian of any given place.

The Chinese were the earliest observers of the property of the magnet of turning, when poised on its centre, continually in the same direction. [COMPASS, HISTORY OF.] The natural magnet being, of course, the first employed, it would be difficult to cut it so that the axis of the magnetic power should strictly coincide with the axis of the bar: and hence it was scarcely to be expected, that with an instrument thus formed, the declination should be discovered. The Chinese, however, had observed this phenomenon at an early period, as has been proved by Klaproth in his letter, cited under COMPASS. In the dictionary of Hiu-tchin, the magnet is described as the 'stone by which we give direction to the needle;' and this refers to the date A.D. 121. Again, under the dynasty of Tsin (which, according to Duhalde, is included between the years A.D. 265 and 419), the great dictionary of Poi-wen-yun-fou says, 'they had then ships whose course was directed by the magnetized needle;' and in another place, quoting a work composed in the eleventh century of our æra, we find 'the fortune-tellers rub the point of a needle with the stone of love (the frequent name of the magnet in many distinct languages) to render it capable of indicating the south.' (*British Annual*, 1837, p. 291.)

Though there is no reason to believe that the Chinese

were acquainted with any other method of making artificial magnets than by friction upon the natural one, yet as all artificial magnets, however produced, have precisely the same directive properties, we can hardly conceive it possible that a people so remarkable as they are for observation could fail to discover that the needle did decline from the true geographical meridian. 'Indeed (as Mr. Davies observes in his *History of the Mariner's Compass* before referred to, in the *British Annual*), when we look at the lines of equal variation in the Indian seas, which is peculiarly the great inexplicable region of our time, and which throws suspicion on every theory of terrestrial magnetism, and suppose they were in a similar state then, we cannot think the Chinese could remain ignorant of it, whilst their commerce extended to the Persian Gulf and the Red Sea.' But we are not left entirely to conjecture, nowever probable, on this head, as there is at least one authority in the Chinese annals which is sufficiently decisive and is borne out by collateral evidence. 'The magnet is covered with small points (hair) of a slight red tinge, and its whole surface is rough. It attracts iron, and adheres to it; and is accordingly called the stone which sucks iron. The Hi-nan-chy, a dark blue stone, is also a dark-coloured loadstone. When an iron point is rubbed with the loadstone, it acquires the property of showing the direction of the south; nevertheless, it always declines to the west, and is not due south.' And, after describing the construction of the compass, the passage proceeds to say that the instrument 'indicates the south, but always with a declination towards the point ping, that is to say, it is $\frac{1}{2}$ to the south.'

The earliest mention of the magnetic declination amongst other than Chinese writers, is in a manuscript known as the Adsigner or Leyden Manuscript. The first distinct notice of it was taken by Senebier of Geneva; and ample extracts from it, both in the original Latin and English translations, were given by Cavallo in a supplement to his *Treatise on Magnetism*, in 1795. This manuscript has been the subject of much discussion; but its authenticity is still greatly doubted.

It has been usual among European writers to refer the discovery of the declination of the needle to Columbus, on his first voyage of discovery in 1492. This opinion rests entirely on the testimony of the son of that great navigator, who states the circumstance in the life of his father, with considerable probability of its being a real case. It is however hardly to be conceived, that the compass should have been in use amongst the enterprising sailors of Europe, upon voyages so extensive as were then frequently undertaken, without the circumstance being not only observed by some, but known to all who were engaged in maritime affairs. At all events, it appears from various printed works and manuscripts to have been familiarly known very soon afterwards to all the commercial nations of Europe.

When it was found that the needle declined from the meridian by different quantities in different places, it was still assumed that at each given place the declination was constantly the same. In 1581 Burrough published his 'Discourse on the Variation of the Compass,' in which he states as the result of numerous observations, that the declination at Limehouse was 11° 15' E.; but in 1633, Gillebrand, the Gresham professor of geometry, found by careful observations that it only amounted to 4° 5' E. It has indeed been stated by Bond, that the variation of the declination was first discovered by Mair, and secondly by Gunter; but as he gives us no authority for this assertion, we are unable to judge of its truth or falsehood. Bond was addicted to paradox, and his statements should therefore be received with caution.

Careful observations (subject, however, to several sources of then unsuspected error) have been made from that period down to the present time; and they all concur in showing that this variation of the declination is continually going on, though not with a uniform angular motion. It was therefore inferred, that the needle would continue to revolve round the horizon by slow degrees, till at last it came round again to any given position; and it appears to have been suspected by some, that the irregularity of its indicated motions was only apparent, and arising either from the imperfection of the instruments employed, or the inaccuracy of the observations themselves. The scientific world was, consequently, not prepared to expect the results of Major Sabine's observations on the declination, and the truth which they unfolded; when in 1818 he determined it

to be $24^{\circ} 30' W.$, and four years afterwards to have retrograded to $24^{\circ} 12'$, at London. Subsequent observations, however, bear out this conclusion; and not only do the observations made in this country but throughout Europe undeniably establish the fact, that the western declination had about 1818 or 1820 attained its maximum value, and that the needle, instead of continuing to gradually move round the points of the horizon, is now returning towards the geographical meridian. The general opinion is therefore that the needle performs a series of oscillations on each side of the meridian, and after attaining its extreme limit returns again through another slow oscillation. As no easterly declination equal in quantity to the recent westerly maximum value has been observed with care, we are left only to conjecture on this point. If, indeed, we adopt this hypothesis, and take Bond's authority for the declination being 0 in 1657, we ought to expect on such an hypothesis that it will be 0 again in 1979, and attain its greatest easterly value in 2140. We are not, we confess, very devoted believers in the opinion that its oscillations are regular; and we think we could furnish strong reasons for our scepticism on this head: but while so few steps have been made towards a satisfactory theory of terrestrial magnetism, it would be rash to affirm that conclusive reasons can be given for either one opinion or the other. At all events, the popular hypothesis depends entirely on an analogy supposed to hold true between the pendulum and the magnetic needle, in a case where the analogy is unphilosophically applied, that is, where the analogy of the causes is by no means apparent, and where there even seems to be a direct contrast between them.

The daily variation of the declination was first observed by Graham in the early part of the last century. He found by very careful experiments upon excellent needles, that the declination was not uniform during the whole period of a day; sometimes being to the east, and sometimes to the west of the general mean declination at the time and place of observation. Canton, less than half a century later, made a considerable number of observations, and a great number of experiments on a subject, which he, like Graham, supposed to be collateral with it,—the influence of temperature upon the intensity and direction of the needle. These inquiries have been pursued with great success by Mr. Christie of the Royal Military Academy, and M. Kupfer of Casan. Separate parts, too, of this inquiry have been attended with very curious results in the hands of Mr. Barlow, likewise of Woolwich Academy, on the influence of high temperatures; and by Colonel Beaufoy, in his careful observations on the actual daily variation for several years before his death.

It may be sufficient here to state the results, and refer to the articles **MAGNETISM**, **TEMPERATURE**, and **VARIATION** for details of the methods of observation and the theoretical views which have been proposed to account for the phenomenon.

The needle attains its maximum easterly variation from the mean between seven and eight in the morning; it moves westerly till about two in the afternoon, when it attains its westerly maximum; it then returns eastward again till the evening; after which a slight westerly motion succeeds; and this is finally followed by a return easterly during the night, which continues till from seven to eight the next morning, when it is found to be nearly the same as it was twenty-four hours before. These oscillations were found by Colonel Beaufoy (as the mean of five years' observations) to have the greatest amplitude in June and in August, while Canton and Wargentein fix it in July. It is however certain that it is greater in the hotter than the colder seasons of the year in England, and throughout Europe; and this will probably also be found to be the case in all parts of the world.

For fuller details on all these subjects, reference is made to the words before quoted; this article being intended only as a slight historical sketch preliminary to the reader's understanding the general state of the science. To these articles we more especially refer, because coming later in the order of time of publication, we shall be enabled to bring before the reader some important inquiries, which we have reason to know are in existence, but not yet before the world.

DECOCTIONS are formed by subjecting the harder parts of plants, which are not easily penetrated by liquids, or are insoluble in water of a low temperature, to

the process of boiling, generally in water, but sometimes in oil. By this means much of the substance is dissolved, and the active principles of the plant are imbibed by the fluid, which is then used medicinally either internally or externally. This method of extracting the medicinal properties of plants is inadmissible when their powers depend upon any aromatic or volatile principle, such as essential oils, which are dissipated by the high temperature. In many other instances this process is not only unnecessary but injurious, being employed when infusion is sufficient, even when cold water is used for the purpose of infusion. Of this nature are all purely mucilaginous substances, such as marsh-mallow (*Althæa officinalis*), quince-seeds (*Cydonia vulgaris*), &c., from which Trommsdorf has shown that a purer mucilage, which keeps longer, may be obtained by cold water. All substances, the astringent properties of which depend upon the presence of tannic acid, such as oak-bark, tormentil-root, &c., have their astringent power impaired or completely destroyed by long boiling. Besides, boiling dissolves many principles, such as starch, &c., which are quite inert, and which do not contribute to the efficacy of the medicine, while their presence disposes the decoction to decomposition, a process very apt to occur in decoctions, and rendering them unfit for use in a few days or hours. Decoction is a mode of preparing substances most suitable to those which are both nutritious and medicinal, such as Iceland moss (*Cetraria islandica*). Many principles which are dissolved by the water at a boiling temperature are deposited by it on cooling, on which account the liquid should always be strained while hot, and the contents of the bottle shaken up before each dose be poured out. Aromatic liquids are frequently added to the fluid after it is strained; or the aromatic substance may be placed at the bottom of the vessel into which the hot decoction is strained, and, after being allowed to infuse for a few hours, may then be applied to the use intended. A better method, however, is to add some aromatic tincture after the straining, as the presence of the spirit retards the tendency to decomposition, while it imparts the flavour and qualities of the substances from which it had been prepared.

DECOMPOSITION. When a compound body undergoes an entire change of properties, either spontaneously or from chemical agency, it is said to be decomposed; thus, during fermentation, whether the spirituous, acetous, or putrefactive, the substance undergoing it suffers decomposition, and its elements recombine so as to form new compounds. This distinguishes it from mere mechanical division, to whatever extent that may be carried. [**ANALYSIS; FERMENTATION.**]

DECREE, DECRETA/LES. The term decree (*decretum*) denotes a decision or order by a competent power or magistrate, by which some doubtful or disputed point of judicial inquiry is determined.

We must distinguish between decrees in civil and in canon law.

As to the former, it was usual among the Romans to take the opinion of lawyers in doubtful cases. Such opinions, which were called '*responsa prudentum*,' obtained the authority of law when they were unanimous. (Gai. 1—7.) When all legislative power was centred in the emperors, it became the custom to ask for their opinion and decision in disputed cases. Their decisions were called decrees, and formed a part of the imperial constitutions. [**CONSTITUTIONS; ROMAN LAW.**]

In the same manner in ecclesiastical matters it became usual to ask the opinions of the bishops, particularly of the bishop of Rome. The replies of the pope ultimately obtained great authority, though they had not at first the force of laws. The legislative power still belonged to the councils. But, in the 12th century, the pope being regarded as the highest ecclesiastical authority, the whole ecclesiastical legislation was centred in him. The papal decrees now became the only source of ecclesiastical law, as the imperial constitutions had been for the civil law. The decrees of the pope, which are called *decretales*, may be defined as decisions of the popes in ecclesiastical matters of law. (Gratian *Decret.*, part i.) The decrees of the popes retained their authority as law till the 14th century, when the power of the holy see began to decline.

From the 5th century the *decretales* of the popes have been collected:—1. The compilation of the abbot Dionysius Exiguus extends from 499 to 514. Pope Adrian I. gave a MS. of this compilation to Charles the Great, of which

our present editions are copies. The oldest edition is that by J. Wendelstein, Mentz, 1525, under the title 'Canones Apostolorum, veterum conciliorum constitutiones, decreta pontificum.' 2. The compilation, which is ascribed to Bishop Isidorus of Seville (633—636), is, for the most part, only a copy of the collection of Dionysius. But it became of importance by the edition made in the 9th century of spurious decretals of the popes, from Clement I. (A.D. 100) to Siricius (A.D. 398), on the authority and the independence of the holy see. The object of these false decretals, called those of the Pseudo-Isidorus, or of Isidorus Mercator or Peculator, was apparently to increase the papal power. This collection was considered as authentic during the middle ages, but no person now maintains its authority. (*Pseudo-Isidorus et Turrianus vapulantes*, by Blondell, Geneva, 1628.) The authentic Isidorus was first edited at Madrid, 2 tom. 1808 and 1821, and the Pseudo-Isidorus is in Merlin's collection, Paris, 1523. 3. Some other collections of Reginus, Prüm, Burchardus of Wurms, and Ivo of Chartres. They may be considered as preparatory to the collection of Gratian. [CANON LAW.]

After the time of Gratian many new collections were made. The most important are:—1. The collection of Bernardus Papiensis (A.D. 1213), called *Breviarium Extravagantium*. It contains partly decretals, which were omitted in the work of Gratian, and partly the decretals of the popes from Alexander III. 2. The collection of Petrus Beneventanus, published by the authority of Pope Innocent III. which contains the decretals of the twelve first years of the reign of that pope. 3. The collection of Joannes Valensis, who collected the decretals of Alexander III., which Bernardus Papiensis had omitted, and those of the popes to Innocent III. 4. As the collection of Petrus Beneventanus contained only the decretals of the first twelve years of the reign of Innocent, a collection of the decretals of the following years of this pope was made by an unknown author. 5. Under the public authority of Pope Honorius III. a new collection, containing the decretals of this pope, was published about the year 1226 by an unknown author.

These five collections, often called the *Quinque Compilationes*, were edited together under the title '*Antiquæ Collectiones Decretalium, cum Ant. Augustini and Jac. Cujacii notis et emendationibus*,' Par. 1609.

The collections after the time of pope Honorius III. form parts of the *Corpus Juris Canonici*. [CANON LAW.]

(J. H. Bœhmer, *De Decretalium Pontificum Romanorum varis collectionibus et fortuna*, prefixed to the 2nd volume of his edition of the *Corpus Jur. Can.*)

DECREE. [EQUITY.]

DECREMENT. [INCREMENT.]

DECREPITATION is the name given to a series of slight explosions, which occurs when various bodies, especially certain salts, are subjected to heat; and it is generally attributed to the loss of water which they contain mechanically deposited between their particles. The noise which occurs when common salt is heated affords a familiar instance of decrepitation.

DECURIONES, a term which denotes certain persons who corresponded to the senate at Rome, in the Roman towns and colonies in Italy which enjoyed free municipal rights. The body of the decuriones was called *ordo decurionum*, and in later times also *curia decurionum*, whence the members of the order were also designated by the name *curiales*. The whole administration of the internal affairs of such towns and colonies was in their hands. They were required to have a certain estate, and to be at least twenty-five years old. It is commonly said that their number was ten, but it was usually greater, and sometimes amounted to 100 members. At the head of the body were the *duumviri*, i. e. two men, like the two consuls, who presided in the Roman senate. Those municipal corporations forming, as to their internal administration, little republics, the citizens had the right of choosing the *duumviri* just as the citizens of Rome elected their consuls; but under the emperors they were deprived of this privilege, and the decuriones at the same time lost their power. The municipal corporations were administered by officers appointed by the emperor; and the decuriones were only employed to receive the taxes, which subjected them to a great responsibility. The office of a decurion being now considered as a burden, was no longer sought after, and lost its former importance. (Sigonius, *De Antiq. Jur. Ital.* ii. 4.)

DEDICATION. [CONSECRATION.]

DEE, the River, rises in Merionethshire, of which it drains the eastern districts and also the south-eastern part of Denbighshire. It afterwards separates Denbighshire from the detached portion of Flintshire and from Cheshire, but the lower part of its course is entirely within Cheshire. The lake of Bala or Llyn Tegid, which may be considered as the source of this river, receives several mountain-streams, one of which is called Dee [BALA-POOL]. The waters of this mountain-lake are discharged at its north-eastern corner by a stream of considerable size and depth, which is soon increased by other considerable mountain-streams, as the Treveryn and Alwen. The Dee so far flows in a fine open valley, and its course is not very rapid till it reaches Corwen. Here the river begins to descend from the mountain table-land of North Wales, and in ten miles from Corwen to Trevor it probably falls above 300 feet; its course in this part is consequently extremely rapid, though without cataracts. Below Trevor it enters the plain, in which it runs with numerous windings upwards of thirty-five miles to the tideway at Chester. Here it is joined by the Alyn from the west, and changes its western course into a northern. At Chester the Dee is about 100 yards wide, and runs farther down in an artificial channel along the marshes for about nine miles. The river now enlarges into a spacious æstuary three miles across, which at high water forms a noble arm of the sea; but at ebb-tide it is dry, and resembles an extensive dreary waste, covered with sand and ooze, through which the river runs in a narrow and insignificant stream. It enters the sea near the island of Helbree, where the æstuary is about six miles wide. In its natural state the Dee is wholly unnavigable; but by means of a weir at Chester, the water is dammed up so as to allow the passage of small boats two or three miles above Chester. The whole course of this river from Bala Pool to the beginning of the æstuary may be about seventy miles.

DEE, JOHN, a distinguished astrologer and mathematician, was the son of a wealthy vintner, and born in London in 1527. Lilly says he was a Cambro-Briton, but this is not in accordance with better authorities. At the age of fifteen he was entered of St. John's College, Cambridge, where his attention seems to have been chiefly directed to mathematical, astronomical, and chemical studies, and his assiduity was there, as through life, even to extreme old age, truly remarkable. At twenty he made a twelvemonths' tour on the continent, chiefly in Holland, for the purpose of scientific intercourse; and returning to Cambridge, was made one of the fellows of Trinity Coll, upon its foundation by Henry the Eighth in 1543; and in 1548, the suspicions entertained of his being addicted to 'the black art' induced him again to go abroad, having first taken his degree of A.M. Whether this prejudice really arose from his having already begun the astrological career for which he was in subsequent life so celebrated, or whether it arose simply from his astronomical pursuits and his mechanical inventions, there is no distinct proof. Judging from other circumstances, especially in connection with the vulgar belief, even among the learned, that all exercise of the powers of natural agents in an uncommon manner was only an exercise of the 'powers of darkness,' we should incline to the latter opinion: whilst, judging from his later life, we should be induced to adopt the previous hypothesis in accounting for the annoyances he met with at Cambridge.

His first residence on this second continental visit was the University of Louvain, at that period in high repute as a place of education; and he was much esteemed for his mechanical skill and his intellectual resources, which, combined with his manly character, caused him to be visited by persons of the highest rank. Two years afterwards he went to France, where he read lectures on the *Elements* of Euclid at Rheims. The character of the 'lectures' on Euclid was in those days extremely different from that of our own time. A series of speculations in all the sciences, whether physical, moral, or mental, was usually given under this title, the propositions of Euclid being taken as so many 'pegs to hang a speech upon.' The more visionary and romantic of these 'lectures' generally contrived to render a course on Euclid a discourse on all the dogmas of the schoolmen of the middle ages, whilst the more reasonable and sober of the lecturers confined their discourses to natural phenomena and the practical applications of geometry. It is almost unnecessary to say that a proof that 'spirits

would be in earth and heaven at the same time' (founded on Euc. i. 37), would be more attractive in an academical course than any 'vulgar mechanical' application of the same proposition could be. Of Dee's lectures we may form a tolerably good estimate from his preliminary discourse in Billingsley's English Euclid, and a few other occasional paragraphs of his in that work. It places Dee's acquirements in a very favourable light; and his judgment, considering his time and circumstances, in one still more favourable. The dissertation of Dee is however to be found in works subsequently printed and much more easily obtained; as in Leake and Serle's Euclid, two or three editions, &c. To read that dissertation is sufficient to convince us that his lectures would be received at Rheims 'with great applause,' as indeed from direct testimony we otherwise know they were.

In 1551 he returned to England, and was presented to King Edward VI by Cecil, and a pension of a hundred crowns was assigned to him. This he however relinquished for the rectory of Upton-on-Severn.

Shortly after the accession of Mary, he was accused of 'practising against the queen's life by *enchantment*;' so that his fame as a dealer in the black art still clung to him. This charge was founded on some correspondence which was discovered between him and the 'servants of the lady Elizabeth;' and it led to a long and tedious imprisonment, with frequent examinations; but as nothing could be established against him, he was ultimately (1555) set at liberty by an order of the council.

On the accession of Elizabeth, Dee was consulted by Lord Dudley respecting 'a propitious day' for the coronation. The queen, to whom he was presented, made him great promises. In 1564 he again visited the continent to present a book which he had written and dedicated to the Emperor Maximilian, under the title of *Monas Hieroglyphica*, and which he printed at Antwerp in that year; and within the year he returned to England.

There is reason however to doubt whether the charge of neglecting Dee, brought against Elizabeth and her ministers, is well made out, however strongly and confidently it has been assumed and repeated. Even this visit to the court of Maximilian might have had an object very different from the ostensible one. There is much probability in Lilly's statement, who says, 'to be serious, he was queen Elizabeth's intelligencer, and had a salary for his maintenance from the secretaries of state. He was a ready-witted man, quick of apprehension, and of great judgment in the Latin and Greek tongues. He was a very great investigator of the more secret hermetical learning, a perfect astronomer, a curious astrologer, a serious geometrician; to speak truth, he was excellent in all kinds of learning.' Lilly's *Memoirs*, p. 224. Where could a man better adapted to the purpose of 'secret intelligence' than such a one be found? This view, too, is borne out by many striking circumstances. Being in 1571 seized with a dangerous illness in Lorraine, the queen sent two physicians to his relief. This is an act the signification of which cannot be doubted.

He afterwards returned to England and settled at Mortlake in Surrey, where he led a life of privacy for some years, devoting himself to study with great ardour, and to the collecting of astronomical and philosophical instruments, not omitting of course a sufficient number of beryls, talismans, &c. His reputation as one who dealt with the devil seems to have strongly manifested itself during this time in his own vicinity, as the mob in 1576 assembled, and destroyed all his collection, or nearly so; and it was with difficulty that he and his family escaped the fury of the rabble.

In 1578, the queen being much indisposed, Mr. Dee was sent abroad to consult with the German physicians and philosophers (or rather astrologers) relative to the means to be employed for her recovery. This was at least the ostensible object; but as no account of the result of this mission exists, except that we know that the queen recovered, we may be led to infer that it was a secret political mission. After his return to England he was employed by the queen to draw up a condensed account of those countries which belonged to her crown, on the ground of being discovered by British subjects, both as to geographical description and the recorded and other evidence upon which her claim rested. With his usual activity he speedily accomplished his task, and in an incredibly short time he presented her majesty with two large rolls in which the discovered coun-

tries are geographically described and historically illustrated. These two curious MSS. still exist in the Cottonian Collection in the British Museum. About this time, too, he paid much attention to the reformation of the Calendar, a treatise on which subject by him, and which is considered both 'learned and rational,' is still in manuscript in the Ashmolean Library at Oxford.

Most of the proceedings and writings upon which his fame with posterity as an astrologer rests, were written subsequent to this period, and he was now upwards of fifty years of age. This is not the general period at which men of activity both of mind and occupation sink into dotage; and it is impossible, taking into account several of the succeeding circumstances of the life of Dee, to imagine that this hypothesis can be applied to his case, in explanation of the extravagances which he perpetrated about this time, and soon after. The belief in supernatural agency was general at that period, and the belief in the power of controlling that agency was equally general, we may say universal. That Dee, admitting this in common with all the orthodox whether of the Catholic or reformed religion, was liable to be the dupe of crafty men, older than himself, is evident, and that with a strong and active imagination he should be led to interpret any sensible phenomena in accordance with it, is extremely probable. Whether he intended to be understood literally, or merely to express under those disguises information and memoranda of a very different nature, it is difficult now to determine. We incline to the latter opinion, and we think this view is borne out by circumstances; we shall, however, annex the usual account, which does indeed contain the ostensible view of his later life.

In the year 1581 he took into his service an apothecary of Worcester, named Edward Kelly, as an assistant. The 'conversations with spirits' were held by Dee, in common with this person; and indeed Kelly was in general Dee's amanuensis during the time they were together. They had a black speculum, of what material cannot be ascertained, but it is generally said 'a polished piece of cannel coal,' in which the angels Gabriel and Raphael appeared at their invocation. Hence Butler says

'Kelly did all his feats upon
The devil's looking-glass—a stone.'

The 'Book of Spirits,' is not, however, to be considered a fair sample of Dee's absurdity, if taken literally; and we are not sure that Dee was himself the author of it. It was published in 1659, more than half a century after Dee's death; and hence its authenticity is very questionable; but even admitting its authenticity, we can only infer from it that it was in reality only an envelope of other information which it was not considered safe to commit to writing in an intelligible form, nor to trust entirely to the memory. Possibly, indeed, it might have been a mere cipher, in which special passages that were worked into the general discourse were to be taken in a secretly specified order, so as to express other facts of a political nature. This was a favourite method of cipher at that period.

In 1583, a Polish noble, named Albert Laske, palatine of Siradia, being in England, Dee and Kelly were introduced to him; whether with a political object or not, no direct evidence exists to inform us, but they accompanied him to Poland. It is said that the attachment arose from the similarity of their pursuits, that he soon became weary of them from finding himself abused by their idle pretensions, and that, to get rid of them, he persuaded them to pay a visit to Rodolph, king of Bohemia; that, moreover, though a weak and credulous man, Rodolph was soon disgusted with their nonsense; and that they had no better success with the king of Poland; but that they were soon after invited by a rich Bohemian noble to his castle of Trebona, where they continued for some time in great affluence, owing, as they asserted, to their power of transforming the baser metals into gold.

It was very probably from the circumstance of Laske's being addicted to astrology and alchemy, as well as the king of Poland, that Dee was employed by the queen's crafty ministers as a fitting person for a political mission to that country, in the real character of a 'secret intelligencer.' It was in keeping with the unvarying policy of Elizabeth's government, and with the habits and previous occupation of Dee. The ridiculous pretensions which he and Kelly set up were well calculated to lull all suspicions of their real purpose. No other hypothesis seems capable of affording a key to Dee's conduct during this singular excursion;

and all the circumstances admit of complete explanation by it.

Kelly appears to have been one of those sordid and servile characters that look only at the immediate gain to be made of each single transaction, without having either principle or honour in his composition. Dee, on the contrary, was, as Lilly in his gossiping memoirs tells us, 'the most ambitious man living, and most desirous of fame and renown, and was never so well pleased as when he heard himself styled Most Excellent.' Lilly also gives a curious narrative of the means by which the servant Kelly obtained the art of transmutation from a poor friar, with whom Dee would have no intercourse; and that when the secret was obtained, the friar was made away with; and one reason given by this arch-knave of the Protectorate, Butler's 'Sidrophel,' why 'many weaknesses in the manage of that way of Mosaical learning ('conference with spirits,' in the book ascribed to Dee), was because Kelly was very vicious, unto whom the angels were not obedient, or willingly did declare the questions propounded.'

Dee and Kelly separated in Bohemia, the former returning to England, the latter remaining at Prague. Of the circumstances attending this rupture nothing is certainly known; though the narrative given by Sidrophel is characteristic enough of Kelly's character. See William Lilly's History of his Life and Times from 1602 to 1681, p. 224. Baldwin's Edition.

In 1595 the queen appointed Dee warden of Manchester College, he being then sixty-eight years of age. He resided there nine years; but from some cause not exactly known he left it in 1604, and returned to his house at Mortlake, where he spent the remainder of his days. He died in 1608, aged 81, leaving a numerous family and a great number of works behind him. 'He died,' says Lilly, 'very poor, enforced many times to sell some book or other to buy his dinner with, as Dr. Napier of Linford in Buckinghamshire oft related, who knew him very well.'

Had Dee lived in better times, his great talents, application, and ambition, would have won for him the highest honours; as it was, he was merely the spy of Elizabeth's base ministry, and to effect that purpose obliged to have recourse to stratagems which debase the moral as well as the intellectual character. We have seen his reward too, penury in his old age.

Dee's writings are very numerous, several of which still remain in MS. A catalogue of his printed writings may be seen in his *Compendious Rehearsal*, or his letter to Whitgift; and from these it appears that he then had by him more than forty unpublished writings, the titles of which he gives.

DEED (in law), an instrument in writing or print, upon paper or parchment, comprehending the terms of agreement between parties able to contract, duly sealed and delivered. Deeds are of two kinds, indented and poll: a deed indented is called an indenture, and has a waving line cut (*in modum dentium*) on one of the edges of the material upon which it is written, usually the top edge; and when the deed consists of more sheets than one, on the first sheet only. The term indenture implies that the deed is of two parts, and that they were divided by the line in order to afford additional means of authentication, but, except in the case of leases, marriage settlements, partnership deeds, and some few others, there are seldom more parts than one. In deeds effectuating modern transactions, indeed, the expense of stamps is so heavy, that frequently, where two or more parties are equally interested in a deed, it is deposited with some person for their joint use. Hence the term indenture, in common acceptation, now implies little more than that the deed is made by and between two or more parties. Antiently some word, as for instance 'chirographum' (whence 'chirograph'), was written in capital letters upon the part where the parchment or paper was to be divided, and afterwards cut in an indented or, in some cases, a straight line.

A deed poll is cut even, or polled at the edges, and is usually of one part only, *i. e.* the deed of one party, or of several parties of the same part. The form commences in the mode of a declaration, 'Know all men by these presents, that,' &c.; the form appropriated to an indenture or a deed among several parties is 'This indenture, made, &c. between, &c. Witnesseth,' &c. A deed *inter partes* is not necessarily indented, except in those cases where an indenture is required by statute, and except in the working

of an estoppel. [ESTOPPEL.] The indenting is not essential, even though the instrument should commence 'This indenture,' &c. It has been said that the indenting may be supplied after the deed is executed, and even in court; but in all cases where the indenting is essential to the validity of the deed, it seems clear that this must be a misake.

A deed, to be absolute and irrevocable, must be founded on a valuable or good consideration, untainted by anything immoral, illegal, or fraudulent, though a gift or voluntary conveyance will be effectual as between the parties, and is only liable to be questioned in certain cases by creditors or subsequent purchasers; and a voluntary deed may become irrevocable by a subsequent sale by the grantee of the subject-matter conveyed by it.

Antient deeds were short, and suited to the simplicity of the times. When transactions became more complicated, it was customary to divide deeds into several formal parts; but it is not absolutely necessary that a deed should be so divided, provided there are sufficient words to show the meaning and intention of the parties. These formal parts are, 1. The premises: that is, the date, the parties' names and description, the recitals, the consideration and receipt thereof, the grant, the description of the things granted, and the exception, if any; 2. The habendum, which defines the estate or interest to be granted; 3. The tenendum, which was formerly used to express the tenure by which the estate granted was to be held; but since freehold tenures have been converted into common socage, the tenendum has grown out of use; 4. The reddendum, the reservation of some new thing, as rent, to the grantor; 5. The condition (if any) annexed to the grant; 6. The warranty; 7. The covenants: the office of these two last, in modern conveyances, is served by special covenants for the validity of the title, and to do or abstain from doing certain specified acts; 8. The conclusion, which mentions the execution, &c.

Previous to its execution, the deed should be read, if any of the parties require it; or, as to that party, it may be avoided. The modern mode of executing deeds is by signing, sealing, and delivering. Signing is not essential to the validity of a deed, though it is required as to less formal instruments by the statute of frauds, 29 Ch. II. c. 3; but sealing is absolutely necessary, which is the most antient mode of authentication, and has been in use from the earliest times. At present the seal affords no real security against fraud, for any impression upon wax or other substance employed is sufficient; indeed it is generally affixed by the stationer who engrosses the deed, and it is not even necessary that there should be a seal for each party; one is sufficient for all. In some of the American states the impression upon wax has been disused, and a flourish with the pen at the end of the name, or a circle of ink, or a scroll, is allowed to be a valid substitute for a seal. The last essential to the due execution of a deed is delivery, except in the case of a corporation, where sealing by the common seal has the effect of delivery. The usual manner of delivering a deed is for the executing party to say, 'I deliver this as my act and deed;' but any less formal mode by which the party signifies his intention to deliver it will be effectual. A deed may also be delivered as an escrow, *i. e.* to a third person to keep till something is done by the grantee: when the condition is performed the deed becomes effectual. A deed takes effect from the delivery, and not from the date, and therefore if it have no date, or a date impossible, the delivery ascertains the time from which it is to take effect. Evidence is admissible also of delivery on a day different from the date written. The execution is usually attested. Enrolment and registration are rendered necessary in some cases by statutory enactment, and the revenue laws have imposed certain stamps upon every description of deeds, the absence of which prevents them from being admissible in evidence.

The principal rules for the interpretation of deeds are, that the effect be fair and reasonable, and as near as possible to the apparent intent of the parties as the rules of law will admit: that the construction be made upon the entire deed, and not upon disjointed parts: that where the intention is clear, too minute a stress be not laid on the strict and precise signification of the words, and that if there be two clauses totally repugnant to each other, the first shall be received, and the latter rejected. There are many other rules of construction, which are exactly the same in courts of law and equity. Courts of equity also rectify mistakes in deeds, and give relief in cases of fraud, and where instruments are lost, &c. [EQUITY.]

After execution, a deed may become void by erasure, interlineation, or other alteration in any material part; but, generally speaking, such alterations will be presumed to have been made before the execution, if nothing appear to the contrary, or there be no cause to suspect that it has been done in a clandestine manner. A grantee may also disclaim the grant or disagree thereto; and a deed may be destroyed or cancelled, but such destruction or cancellation will not re-vest the thing granted in the grantor, though all personal engagements established by the deed between the parties will be put an end to.

A confirmation is an assent to an estate or interest already created, by which act the person assenting confirms and gives validity to the estate or interest so far as he can. A confirmation can only have this effect with respect to estates voidable or defeasible: it has no operation upon estates which are absolutely void. (Butl. n. Co. Litt., 295 b.)

(Shep., *Touchstone*; Dixon; Co. Litt.; Cruise's *Digest*.)
DEEMSTERS. [MAN, ISLE OF.]

DEER, CER'VIDÆ, a family of solid-horned ruminants, the horns caducous, and belonging, generally speaking, to the male only.

HORNS.

Before we enter upon the other details of the natural history of the species composing this noble natural group, it will be necessary to say a few words on the development of the horns, which form so remarkable a part of the organization of the animals, as weapons of attack and defence, and as being indicative of the presence or the absence of the power of continuing the species, and the more or less vigorous degrees of that power.

In the Museum of the Royal College of Surgeons (*Physiological Series*, No. 179) will be found a section of part of the *os frontis* and of the base of a fallow deer's horn (*Cervus Dama*), the growth of which is nearly completed. It shows the horn to be a continuation of bone from the outer table of the skull, and the velvet-like covering of the horn to be equally continuous with the integuments of the head. It shows also the burr or pearl which has been formed round the base of the horn, and illustrates the effects of this part on the growth of the horn.

In the formation of the burr, which is the last part of the process, and takes place rapidly, the osseous tubercles of which it is composed are projected outwards, and by their pressure induce absorption of the vascular external covering, and increasing at the same time laterally, they enclose and compress the blood-vessels; thus, in a short space of time, the circulation is entirely obstructed, and consequently the whole of that once very vascular and sensible tegument loses its vitality, dries, shrinks, and peels off, leaving the horn a naked insensible weapon. In one of the branches (the brow antler) in this preparation, the whole of the vessels appear to have been thus obliterated; in the other a slight degree of vascularity remains, and one of the large external arterial branches is still uncompressed (*Catalogue, Physiol. Series*, vol. i.) The beautiful preparations illustrative of the process are numbered 163 to 187, both inclusive.

The rapidity with which this firm mass of bone is secreted is worthy of note. The budding horns of a male wapiti were several inches high in ten days from their first appearance; a month afterwards there was an interval of two feet between them, measuring from branch to branch.

It is in the spring generally that the reproduction of the horn is begun. From the place whence the old horn had been separated and cast, and which at first is apt to bleed, but soon

is skinned over with a fine film, the new horn sprouts. At this time there is a strong determination of blood to the head, great in proportion to the demand for such an enormous and ultimately solid secretion. The vessels from the roots swell, the vascular horn pushes up, protected by a delicate and soft covering. In this its early stage it is nearly cylindrical, and the quantity of animal heat which it contains may be in some degree imagined by gently grasping it with the hand. Gradually the antlers appear; the whole 'head,' to use the sporting term, is developed, and becomes of the firmest solidity; the animal feels its powers, and proceeds to rub off the drying and decaying 'velvet,' which may be seen at this period hanging from the horn in ragged strips, against trees and other resisting bodies, leaving at last the magnificent ornament and weapon with only the traces on its now hard surface of the blood-vessels which had produced it. Then it is that the deer, conscious of his strength, comes forth in all his grandeur, ready to do battle with any creature, even man himself, who may dare to invade his haunts. Fierce fights ensue, and the strongest male reigns paramount. The rutting season dies away, spring returns, the antlers are shed, again to be regenerated in time for the season of love.

In the common stag or red deer (*Cervus Elaphus*), the shedding of the horns takes place about the end of February or during March. The fallow deer sheds his horns from about the middle of April to the first weeks of May.

For the production of these annually regenerated bony masses Nature has provided with her usual care. 'We find it a common principle in the animal machine,' says John Hunter, 'that every part increases in some degree according to the action required. Thus we find muscles increase in size when much exercised; vessels become larger in proportion to the necessity of supply, as for instance in the gravid uterus. The external carotids in the stag, also, when his horns are growing, are much larger than at any other time; and I have observed that in inflammation the vessels become larger, more blood passes, and there appear to be more actions taking place; but the nerves do not seem to undergo any change. The nerves of the gravid uterus are the same as when it is in a natural state; neither do the branches of the fifth and seventh pair of nerves in the stag become larger.' (*Hunter on the Blood*.)

But it must not be supposed that the antlers reach their full amplitude in the first years of the male deer's life. In the stag or red deer the horns of the male do not appear till its second year, and the *first* which is shed (fig. 1) is straight and single, like a small thrust-sword or dagger, whence the young male is termed by the French *daguet*. The *next* horn has generally but one antler, as in fig. 2; but it has sometimes two, and even three (figs. 3, 4, which are horns of stags in their third year). The *third* horn has three or four antlers, and sometimes as many as five or six, which are also the numbers of the *fourth* (figs. 5, 6). Up to this time the young male is called a young stag—*jeune cerf*. The *fifth* horn bears five or six antlers of the degree of development indicated in figs. 6, 7, or 8; in this stage the animal is called by the French *cerf de dix cors jeune-ment*. The sixth horn, which the stag sheds at about seven years of age, is that which bestows upon the stag the appellation of *cerf de dix cors*.

The proportional length, direction, and curvature of the antlers vary; and it often happens that there is one more or less on the one side than on the other. Independently of the number of antlers, the horns become larger, the superficial furrows more marked, the burr is more projecting, and the prominences of the frontal sinus which support

[Horns of Stag, *Cervus Elaphus*, Left Horns.]

the horns become shorter and wider every year. By such signs is the age of old stags, or those of from eight years upwards, determined; for after the seventh year the number of the antlers is regulated by no fixed rule; they are multiplied towards the summit of the beam, where they are conjoined into a kind of crown or palmation (figs. 9, 10, 11, 12). The oldest heads do not in general present more than ten or twelve antlers (*tines*, Scotticè); but some have been seen that bore the enormous number of thirty-three. Such was the noble *cerf à 66 cors* killed by the first king of Prussia, and presented by that monarch to Augustus I., elector of Saxony and king of Poland. This noble head is said to be still preserved at Moritzburg.

In all gradations of age after the appearance of the antlers, the second antler is more or less approximated to the first or brow antler, *maître andouiller* of the French; a name given to it because it is the largest.

The sympathy between that part of the system which regulates the development of the horns in the deer tribe and the organs of generation is most remarkable. For instance, if a stag is castrated when his horns are in a state of perfection, they will, it is affirmed, never be shed; if the operation is performed when the head is bare, the horns, it is said, will never be regenerated; and if it is done when the secretion is actually going on, a stunted, ill-formed permanent horn is the result, more or less developed, according to the period at which the animal is emasculated. Any disturbance of the system generally produces a corresponding deterioration in the horn. In the subjoined cut fig. *a* represents the horn of a deer (*Cervus Canadensis*) produced during a voyage from America, and *b* a horn subsequently developed in the French Menagerie by the same individual, which afterwards produced a head of surprising dimensions.

a, Horn of Deer produced under unfavourable circumstances; *b*, horn of same deer produced under more favourable circumstances.

[Horns of a Fallow Deer that were not shed at the usual time in consequence of the castration of the animal. From the Museum of the College of Surgeons.]*

The same system of development which we have observed in the *horn with branching antlers* is in great measure to be traced in the other leading form of *horn*, viz., the *palmated horn*. Taking the horn of the fallow deer (*Cervus Dama*) as an example of the latter, we find the horn first put forth by the buck at two years old, (when he is called a pricket,) a simple shaft, slightly curved, the concavity turned forwards (fig. 1); this curvature the horns retain throughout. The second year there are two antlers directed forwards (fig. 2), and the summit of the horn in some cases begins to spread into a palm (figs. 3, 4,) which afterwards increases, throwing out a greater or less number of dentations on its posterior and superior border (figs. 5, 6, 7, 8). Sometimes one or two of these dentations form true recurrent antlers (figs. 6, 8). Figs. 8 and 9 are horns of the fourth growth, and it will be seen that they begin to be divided above. In the following years the palm is irregularly and variously divided (figs. 10, 11, 12, 13), so that the horns of old bucks are very frequently oddly shaped, and hardly to be recognized. With still more advanced age they continue

[Horns of Fallow Deer, *Cervus Dama*. Left Horns.]

to dwindle. Cuvier, from whom this account and the figures of the growth of the deer's horn are taken, says that it is asserted that these palmated horns of the buck finish by putting on the simple appearance of the horn first developed (*dague*), and states that he in fact possessed the head of a fallow deer which had only simple horns, and whose teeth were ground down to the very roots by long use.

The reproduction of the horns is annual in the deer of

temperate and cold climates; but it has been supposed that some of the species inhabiting hot climates do not cast them every year. The palmated horn seems to be more especially given to those deer which inhabit the northern latitudes;

* It is apparent from the specimen that these horns could never be shed; they form one bony continuance with the os frontis. They are evidently the result of highly disordered functions, and the bony excrescences from the beam seem to have the character of exostosis.

and Colonel Smith is of opinion that it is a provision to enable the animals to remove the snow from their food.

Dental formula, generally speaking, the same as in the giraffes, goats, antelopes, sheep, oxen, &c.; viz., incisors, $\frac{0}{8}$; canines, $\frac{0-0}{0-0}$; molars, $\frac{6-6}{6-6} = 32$.

Of the molars, both in the upper and lower jaws, six are true and six false. In the upper jaw the three first molars are bordered by a thick crest on their internal surface; the three next have all the characters of the molars in the dromedaries. [CAMEL.] In the lower jaw, the first incisor is the longest, the second and the third rather decrease, and the fourth is very small; all have cutting edges. The two first false molars are simple; the third has a process or heel at its posterior part, and the three others do not differ from those of the upper jaw. In the formula given above, the canines are noted as absent; but this general rule is not without exception, some of the species presenting canines similar to those of the *Musks* (*Moschus*) in the upper jaw. The *Muntjak* has these teeth largely developed. (See, p. 362.)

The Deer-tribe possess the *lachrymal sinus*, or as it is often termed the *suborbital sinus* (*larmiers* of the French, *tear-pits* of the English), even more universally than the Antelopes. Under the title ANTELOPE (vol. i. p. 68), will be found a very good description of them, with the different opinions as to their functions, up to the time when the article was written.

The late lamented Mr. Bennett, at a meeting of the Zoological Society (22nd March, 1836), proceeded to remark that it appeared to him that the lachrymal sinus, the use of which has long remained a problem to zoologists, must be referred to sexual relations. Referring to its structure, as to that of a sac, opening externally by a lengthened slit, but perfectly closed within, he remarked, that that organ could not possibly be in any degree connected with the functions of respiration; there being no aperture through it for the passage of air. Its inner surface is covered by a smooth skin, with a few scattered and very short bristles, and is defended by a dark-coloured and copious secretion of ceruminous matter, which has a heavy urinous and sexual odour. He did not feel himself competent, he stated, to explain the precise manner in which this organ is available for sexual purposes; yet he felt convinced that such is its use, from the consideration of its relative development in the several *Indian Antelopes* of the Society's Menagerie.

In the more aged of these individuals, as indeed in the adult *Indian Antelope* generally, the large cutaneous follicle beneath the eye known as the lachrymal sinus, is so prominent as to form a most striking feature in the animal's physiognomy: it never appears as a simple slit, its thickened edges pointing so widely as to be at all times partially everted. When the animal is excited, and it is constantly highly excitable, the eversion of the bag becomes complete, and its thick lips being thrown widely back, the intervening space is actually forced forwards so as to form a projection instead of a hollow: the animal is, on such occasions, delighted to thrust repeatedly the naked lining of the sac against any substance that is offered to him, which soon becomes loaded with the odour that has been referred to as belonging to the secretion. In the second individual, although it is perfectly mature, the protrusion of the inner surface of the sac is not quite to so great an extent as in the more aged male; and the less thickened edges of the sinus allow of a nearer approximation to its closure in the unexcited state of the animal. The youngest male has the lips of the sinus small and closely applied to each other, so as to hide completely the whole of the internal lining of the sac, and to exhibit, externally, a mere fissure: in it the lips are but slightly moved when the animal is interested. The emasculated individual, notwithstanding its full growth, has its suborbital sinus nearly in the same condition as that of the immature male: it is merely a slight fissure, the edges of which are closely applied to each other; and in it those edges do not appear to be at all moved, the animal being generally careless and inanimate. It would consequently seem that the same cause which induced the retention, by this individual, of its immature colours, and which arrested the perfect growth of its horns, was adequate also for the checking of the development of the suborbital sinuses. Those organs, therefore, would appear to be dependent on sexual perfection; and

consequently to be, in some manner yet to be ascertained, subservient to sexual purposes, with the capacity for which they are evidently, in the phases of their development, essentially connected.

Mr. Owen, who had conceived it possible that the secretion of these glands, when rubbed upon projecting bodies, might serve to direct individuals of the same species to each other, remarked that he had endeavoured to test the probability of this supposition by preparing a tabular view of the relations between the habits and habitats of the several species of *Antelopes*, and their suborbital, maxillary, post-auditory, and inguinal glands; in order to be able to compare the presence and degrees of development of these glands with the gregarious and other habits of the *Antelope* tribe. He stated, however, that it was evident from this table, that there is no relation between the gregarious habits of the *Antelopes* which frequent the plains, and the presence of the suborbital and maxillary sinuses; since these, besides being altogether wanting in some of the gregarious species, are present in many of the solitary frequenters of rocky mountainous districts. The supposition, therefore, that the secretion might serve, when left on shrubs or stones, to direct a straggler to the general herd, falls to the ground. (*Zool. Proc.* 1836.)

The reader will find the table above alluded to in the Proceedings of the Zoological Society of London, for 1836.

The osteological structure of the Deer-tribe is such as would be expected when it was necessary that the bony framework should exhibit a union of lightness and strength, necessary for an animal whose life is to depend on its agility and defensive powers. The general character of the skeleton may be collected from the different skulls figured in this article and from the FOSSIL ELK. (p. 364.)

Geographical Distribution.—The form is widely spread, and seems capable of being so modified as to withstand the extremes of heat and cold.

The species are very numerous, and our limits will only permit us to give a few examples of the various sections.

Character of the Family.—Horns caducous or deciduous, proper to the male only, generally. Body plump. Legs slender. *Lachrymal sinuses* under the eyes. A *muzzle* in the greater part of the species. Ears moderate, pointed. Tail very short. *Mammæ* four, inguinal. (Dental formula given above.)

a.

Horns sessile, more or less subdivided, without either basilar or mesial antlers, but terminated by a vast palmation, digitated on its external border only.

THE ELKS.

Example, *Alces Americanus*, *Cervus Alces*, Linn. The Elk or Moose Deer.

This noble animal is, according to Dr. Richardson, the *Ellan*, *Stagg*, or *Aptaptou* of De Mont; *Eslan* ou *Originat* of Sagard-Theodat; *Original* of La Hontan, Charlevoix, Denys, Du Pratz, and of the French Canadians of the present day; *Orignac* (Hist. de l'Amerique), and of the Basque settlers in Canada (De Mont); *Moose Deer* of Dudley, Pennant, and Warden; *Moose* of Umfreville and Heriot; *Mongsoa* of the Algonquins; *Mousöa* of the Crees; and *Denyai* of the Chipewyans.

Description.—This animal is the largest of the genus, being higher at the shoulders than the horse; its horns weigh sometimes near fifty pounds; accordingly, to bear this heavy weight, its neck is short and strong, taking away much of the elegance of proportion so generally predominant in the deer; but when it is asserted that the elk wants beauty or majesty, the opinion can be entertained by those who have seen the female only, the young, or the mere stuffed specimens; for us who have had the opportunity of viewing the animal in all the glory of its full-grown horns, amid the scenery of his own wilderness, no animal could appear more majestic or more imposing. It is however the aggregate of his appearance which produces this effect; for when the proportions of its structure are considered in detail, they certainly will seem destitute of the harmony of parts which in the imagination produces the feeling of beauty. The head measuring above two feet in length, is narrow and clumsily shaped, by the swelling upon the upper part of the nose and nostrils; the eye is proportionably small, and sunk; the ears long, hairy, and asinine; the neck and withers are surmounted by a heavy mane; and the throat furnished with long coarse hair, and,

in younger specimens, encumbered with a pendulous gland: these give altogether an uncouth character to this part of the animal. Its body, however, is round, compact, and short; the tail not more than four inches long; and the legs, though very long, are remarkably clean and firm; this length of limbs and the overhanging lips have caused the antients to fancy that it grazed walking backwards. The hair of the animal is coarse and angular, breaking if bent. Its movements are rather heavy, and the shoulders being higher than the croup, it does not gallop, but shuffles or ambles along, its joints cracking at every step, with a sound heard to some distance. Increasing its speed, the hind-feet straddle to avoid treading on its fore-heels, tossing the head and shoulders like a horse about to break from a trot to a gallop. It does not leap, but steps without effort over a fallen tree, a gate, or a split fence. During its progress, it holds the nose up, so as to lay the horns horizontally back. This attitude prevents its seeing the ground distinctly; and as the weight is carried very high upon the elevated legs, it is said sometimes to trip by treading on its fore-heels, or otherwise, and occasionally to give itself a heavy fall. It is probably owing to this occurrence that the elk was believed by the antients to have frequent attacks of epilepsy, and to be obliged to smell its hoof before it could recover; hence the Teutonic name of *Elend* (miserable), and the reputation, especially of the fore-hoofs, as a specific against the disease.' (Smith.)

In 'A perfect Description of Virginia,' (small 4to, 1649,) we find it thus written: 'The elkes are as great as oxen, their horns six foot wide, and have two calves at a time.' Hearne remarks that the horns of the moose occasionally exceed 60 lbs., and that their texture is harder than that of any other deer-horns to be found in the fur countries. Lawson ('Nat. Hist. of Carolina') says, 'The elk is a monster of the venison sort. His skin is used almost in the same nature as the buffelo's (bison's). Some take him for the red deer of America, but he is not; for if brought and kept in company with one of that sort, he will never couple.* * * His horns exceed (in weight) all creatures which the New World affords.' Dr. Richardson states that he has been informed that the males sometimes attain a weight of eleven or twelve hundred pounds.

Utility to Man.—'The flesh of the moose is very good, though the grain is but coarse, and it is much tougher than any other kind of venison. The nose is most excellent, as is also the tongue, though by no means so fat and delicate as that of the common deer (rein-deer). The fat of the intestines is hard like suet; but all the external fat is soft like that of a breast of mutton, and, when put into a bladder, is as fine as marrow. In this they differ from all the other species of deer, of which the external fat is as hard as that of the kidneys.' (Hearne.) In the 'Perfect Description of Virginia' above quoted, it is stated that the 'skins make good buffe, and the flesh as good as beefe.' Lawson, though he speaks of the good qualities of the skin, does not seem to have so high an opinion of the flesh. 'His flesh,' says Lawson, 'is not so sweet as the lesser deers.' Dr. Richardson remarks that the flesh of the moose is more relished by the Indians and residents in the fur countries than that of any other animal, and principally, he believes, on account of the soft fat. In his opinion, corroborating the old book above quoted, the flesh bears a greater resemblance in its flavour to beef than to venison.

The same author describes the dung of the animal as being in the form of brown oval pellets, and such were the droppings from the individuals kept at the garden of the Zoological Society in the Regent's Park. The skins, Dr. Richardson observes, when properly dressed, make a soft, thick, pliable leather, excellently adapted for mocasins, or other articles of winter clothing. The Dog-ribs, he adds, excel in the art of dressing the skins, which is done in the following manner. They are first scraped to an equal thickness throughout, and the hair taken off by a scraper, made of the shin-bone of a deer, split longitudinally; they are then repeatedly moistened and rubbed, after being smeared with the brains of the animal, until they acquire a soft spongy feel; and lastly, they are suspended over a fire made of rotten-wood, until they are well impregnated with the smoke. This last-mentioned process imparts a peculiar odour to the leather, and has the effect of preventing it from becoming so hard, after being wet, as it would otherwise do. (*Fauna Boreali-Americana*.)

Locality.—'Du Pratz,' writes Dr. Richardson, 'informs us that, in his time, moose-deer were found as far south as the Ohio: and Denys says that they were once plentiful on the Island of Cape Breton, though at the time he wrote they had been extirpated. At present, according to Dr. Godman, they are not known in the state of Maine, but they exist in considerable numbers in the neighbourhood of the Bay of Fundy. They frequent the woody tracks in the fur countries to their most northern limit. Several were seen on Captain Franklin's last expedition at the mouth of the Mackenzie, feeding on the willows, which, owing to the rich alluvial deposits on that great river, extend to the shores of the Arctic Sea, in lat. 69°. Farther to the eastward, towards the Copper Mine river, they are not found in a higher latitude than 65°, on account of the scarcity on the Barren Grounds of the aspen and willow, which constitute their food. I have not been able to ascertain whether they occupy the whole width of the continent or not. Mackenzie saw them high up on the eastern declivity of the rocky mountains, near the sources of the Elk river; but I suspect that they are rarely, if ever, found to the westward of the mountains. Authors mention that the moose generally form small herds in Canada. La Hontan, who travelled in that country in 1683, says, that whilst he accompanied the Indians, they hunted the Elk with dogs when there was a crust on the snow; and that after a chase of a few leagues they generally found ten, fifteen, or twenty of them in a body: in three months his party killed fifty-six, and might have taken as many more. It is probable, however, that La Hontan in this passage confounds the Canada-stag and moose-deer together. He mentions the animal being able to run, in the summer season, for three days and nights in succession, and the excellent flavour of its flesh,—facts which apply to the moose-deer, but not to the Canada-stag; on the other hand, the weight of the horns, which he says sometimes amounts to four hundred weight, is true only of the stag. In like manner the accounts of the other antient writers on Canada are liable to suspicion.'

Habits, Chase, &c.—Lawson observes of the elks that 'they will often resort and feed with the buffelo, delighting in the same range as they do.' Dr. Richardson gives the following succinct account of their habits and food, and of the mode of hunting them.

'In the more northern parts the moose-deer is quite a solitary animal, more than one being very seldom seen at a time, unless during the rutting season, or when the female is accompanied by her fawns. It has the sense of hearing in very great perfection, and is the most shy and wary of all the deer species, and on this account the art of moose-hunting is looked upon as the greatest of an Indian's acquirements, particularly by the Crees, who take to themselves the credit of being able to instruct the hunters of every other tribe. The skill of a moose-hunter is most tried in the early part of the winter; for during the summer the moose, as well as other animals, are so much tormented by mosquitoes, that they become regardless of the approach of man. In the winter the hunter tracks the moose by its foot-marks in the snow, and it is necessary that he should keep constantly to leeward of the chase, and make his advances with the utmost caution, for the rustling of a withered leaf or the cracking of a rotten twig is sufficient to alarm the watchful beast. The difficulty of approach is increased by a habit which the moose-deer has of making daily a sharp turn in its route, and choosing a place of repose so near some part of its path that it can hear the least noise made by one that attempts to track it. To avoid this, the judicious hunter, instead of walking in the animal's footsteps, forms his judgment from the appearance of the country, of the direction it is likely to have taken, and makes a circuit to leeward until he again finds the track. This manœuvre is repeated until he discovers, by the softness of the snow in the foot-marks and other signs, that he is very near the chase. He then disencumbers himself of everything that might embarrass his motions, and makes his approach in the most cautious manner. If he gets close to the animal's lair without being seen, it is usual for him to break a small twig, which alarming the moose, it instantly starts up; but, not fully aware of the danger, squats on its hams, and voids its urine, preparatory to setting off. In this posture it presents the fairest mark, and the hunter's shot seldom fails to take effect in a mortal part. In the rutting season the bucks lay aside their

timidity, and attack every animal that comes in their way, and even conquer their fear of man himself. The hunters then bring them within gun-shot by scraping on the blade-bone of a deer and by whistling, which, deceiving the male, he blindly hastens to the spot to assail his supposed rival. If the hunter fails in giving it a mortal wound as it approaches, he shelters himself from its fury behind a tree, and I have heard of several instances in which the enraged animal has completely stripped the bark from the trunk of a large tree by striking with its fore feet. In the spring-time, when the snow is very deep, the hunters frequently run down the moose on snow-shoes. An instance is recorded in the narrative of Captain Franklin's second journey, where three hunters pursued a moose-deer for four successive days, until the footsteps of the chase were marked with blood, although they had not yet got a view of it. At this period of the pursuit the principal hunter had the misfortune to sprain his ankle, and the two others were tired out; but one of them, having rested for twelve hours, set out again, and succeeded in killing the animal after a further pursuit of two days' continuance. Notwithstanding the lengthened chase which the moose can sustain when pursued in the snow, Hearne remarks that it is both tender-footed and short-winded; and that, were it found in a country free from underwood, and dry under foot, it would become an easy prey to horsemen and dogs. The same author informs us that in the summer moose-deer are often killed in the water by the Indians who have the fortune to surprise them while they are crossing rivers or lakes, and that at such times they are the most inoffensive of animals, never making any resistance.

'The young ones in particular,' says he, 'are so simple, that I remember to have seen an Indian paddle his canoe up to one of them, and take it by the poll, without experiencing the least opposition, the poor harmless animal seeming at the same time as contented alongside the canoe as if swimming by the side of its dam, and looking up in our faces with the same fearless innocence that a house-lamb would, making use of its fore foot almost every instant to clear its eyes of mosquitoes, which at that time were remarkably numerous. The moose is the easiest to tame and domesticate of any of the deer kind.'

With respect to the food of the moose, the same traveller says, 'Their legs are so long, and their necks so short, that they cannot graze on the level ground like other animals, but are obliged to browse on the tops of large plants and the leaves of trees in the summer, and in winter they always feed on the tops of willows and the small branches of the birch-tree, on which account they are never found during that season but in such places as can afford them a plentiful supply of their favourite food; and although they have no fore-teeth in the upper jaw, yet I have often seen willows and small birch-trees cropped by them in the same manner as if they had been cut by a gardener's shears, though some of them were not smaller than a common pipe-stem; they seem particularly partial to red willows' (*cornus alba*). To the eastward of the Rocky Mountains the evergreen leaves of the *gualtheria shallon* form, according to Lewis and Clark, a favourite part of the food of the moose-deer.

The wooden pipe-stems above alluded to and used in Hudson's Bay, are, says Dr. Richardson, about the thickness of a little finger.

It is generally held by zoologists that the American elk and the European or Scandinavian elk are specifically the same. It was the opinion of Buffon that the European elk was not known to the Greeks, nor does it appear to have been noticed by Aristotle. That it was the *ἄλκη* (Alce) of Pausanias, Alce of Cæsar and Pliny, Elch of the Celts, and Ælg or Elg of the northern Europeans, there can be little doubt. Pausanias describes it (ix. 21) as being *ἐλάφου καὶ καμήλου μεταξύ*, 'between a stag and a camel;' and though the accounts of Cæsar and Pliny are mingled with fable, and the former states that his *Alces* are *mutilæ cornibus* (which might arise from the accounts of those who had seen the animal at the period when the horns had exfoliated), the general description and the localities given by both are almost conclusive as to the animal meant to be designated. The 'labrum superius prægrande,' 'huge upper lip,' of Pliny, is very expressive, and the extraordinary development of this part might well recall to a casual observer the general traits of the head of a camel. Whether it was the *ἵππελαφος* (hippelaphus) of Aristotle is a question which will admit of much discussion. The hippelaphus is de-

[*Alces Americanus*.]

scribed by Aristotle (*Hist.*, lib. ii. c. 1) as having a mane near the springing of the shoulder, but the upper part of the neck from that point to the head without that ornament, a beard under the front of the neck, and the head armed with horns approaching to those of the roe (*δορκάς*). Scaliger confesses that he knows not what this animal is; Caius, as quoted by Gesner, considered it to be the elk, and Gesner himself leans to this opinion, which is adopted by Klein and many others. Buffon relies upon two reasons for not confounding the elk with the hippelaphus; one is the size of the two animals, the other the climates which they inhabit. Aristotle makes the size of the hippelaphus nearly that of a stag, which is inferior in bulk to the elk, and he assigns as its locality, Arachosia, a country of Asia about the 83° of longitude, and the 33° of latitude, according to D'Anville's map; whereas the elk never quits the cold countries of the north. Upon the whole, Buffon thinks that the hippelaphus is no other than the stag of Ardennes (a variety of the common stag, *Cervus Elaphus*), which, he observes, is larger than the common stag, and differs from it only in the skin, which is of a deeper colour, being nearly black, but also in the long hair which it carries on the shoulders and under the neck. M. Camus considers that the difference of climate and locality, amounting to more than 15° of latitude and 50° of longitude, operates strongly against the identity of the stag of Ardennes with the hippelaphus. There can be but small doubt that the hippelaphus of Aristotle is not the elk, but some one of the Asiatic species. M. Frederick Cuvier is of opinion that the *Rusa* deer is the species meant. The probability is, that though the European elk will not turn out to be specifically different from the American, it will prove to be a variety when the two animals are carefully compared with each other, which does not as yet appear to have been done. La Hontan hints at differences between them, and Colonel Smith remarks that the lower parts of the antlers of the American elk are more often separated into branches than those of the European.

Mr. Lloyd (*Field Sports of the North of Europe*, vol. ii.) observes that the elk was at one time numerous in most parts of Sweden and Norway; but owing to the increased population, and other causes, it is now only to be met with in particular districts. In Scania, he adds, the most southern province of Sweden, where elks once abounded, none are now to be found.

M. Nilsson states that the elk cannot endure so cold a climate as the stag, the 64° of latitude being the extreme limit at which it is met with in the Scandinavian peninsula.

Mr. Lloyd says that it is reported that the elk not unfrequently attains to the height of seven or eight feet. 'This,' he continues, 'I can readily believe, as Mr. Wise, the Swedish consul-general, had one in his possession a few years ago, which, though only two years of age, measured nearly nineteen hands, or upwards of six feet at the shoulder. I once took the exact dimensions of a rather large male elk that I shot, but unfortunately I lost the

string with which I effected that purpose out of my pocket. Though this animal was not fully grown, it was thought he weighed near one thousand pounds.' The same author states the period of gestation to be about nine months, and that the female brings forth, about the middle of May, from one to three young ones; but it is seldom that she has more than two. At this period the mother retires alone to the wildest recesses of the forest. After a lapse of two or three days, the fawns, which are of a light brown colour, have sufficient strength to follow their dam everywhere; they keep with her until they are in their third year, when she leaves them to shift for themselves.

Mr. Lloyd thus describes the habits and uses of the European elk. 'The elk is a long-lived animal; he does not attain to his full growth until after his fourteenth year. At least so it is to be presumed, as up to that period his horns, which are of a flat form, are annually provided with an additional branch. He sheds his horns about the month of February in each year. The female elk, unlike the reindeer of that sex, has no horns. The horns of the young male elk are perceptible nine months after its birth: for the first year they are cylindrical and short; the second year they are about a foot in length, but not branched; the third year, two points are discernible; the fourth year, three; the fifth, they are full grown in length. From that time forward they yearly increase in breadth, and in the number of branches until there are as many as fourteen on each horn.

'By nature the elk is timorous, and he usually flies at the sight of man. In the rutting season, however, like other animals of the deer kind, he is at times rather dangerous. His weapons are his horns and hoofs; he strikes so forcibly with the latter as to annihilate a wolf, or other large animal, at a single blow. It is said that when the elk is incensed, the hair on his neck bristles up like the mane of a lion, which gives him a wild and frightful appearance.

'The usual pace of the elk is a high shambling trot, and his strides are immense, but I have known him, when frightened, to go at a tremendous gallop. In passing through thick woods he carries his horns horizontally, to prevent them from being entangled in the branches; from the formation of his hoofs he makes a great clattering, like the reindeer when in rapid motion. In the summer season the elk usually resorts to morasses and low situations; for, like other animals of the deer kind, he frequently takes to the water in warm weather; he is an admirable swimmer. In the winter time he retires to the more sheltered parts of the forest, where willow, ash, &c., are to be found; as, from the small boughs of these trees he obtains his sustenance during that period of the year. In the summer and autumn the elk is often to be met with in small herds, but in the winter there are seldom more than two or three in company. At the latter season, indeed, he is frequently alone.

'The flesh of the elk, whether fresh or smoked, is very excellent: the young are particularly delicious. According to Mr. Nilsson, it resembles in taste that of the stag. The tongue and the nose are thought to be great delicacies in Scandinavia as well as in America. Great virtue was once placed in the hoof of that animal, as parings of it were supposed to be a specific against the falling sickness and other disorders; but this idle notion must, by this time, I should think, be nearly exploded. The skin is convertible to many purposes, and is very valuable. Mr. Greiff says—"It is not long since that a regiment was clothed with waistcoats made from the hides of those animals, which were so thick that a ball could scarcely penetrate them." He adds farther, that "when made into breeches, a pair of them, among the peasantry of former days, went as a legacy for several generations."

'The elk is easily domesticated: several instances have come to my knowledge. I had a fawn in my own possession a year ago, but from want of proper nurture, it died. Formerly these animals were made use of in Sweden to draw sledges, but, owing, as it was said, to their speed frequently accelerating the escape of people who had been guilty of murders, or other crimes, the use of them was prohibited under great penalties. Though I apprehend those ordinances, if not abrogated, are obsolete, I am not aware that the elk is ever made use of in that kingdom at the present day, either to draw a sledge, or for other domestic purposes.

'In Sweden, as I have observed, it is contrary to law at

this particular time, to kill the elk at any season of the year: this is not the case in Norway; for in that country, as I have just shown, these animals may be destroyed, with certain limitations as to numbers, from the 1st of July to the 1st of November inclusive. The penalty however for killing an elk out of season, in Norway, is very much heavier than in Sweden; it amounts indeed, including legal expenses, &c., to about 20*l.*, which is no inconsiderable sum in that kingdom.' (Lloyd, *Northern Field Sports*, vol. ii., p. 329 et seq.)

Immediately following the passage above quoted there is a very interesting account of the mode of hunting the elk, in Scandinavia, upon 'skidor,' or snow skates, interspersed, as most of such narratives are, with notices of the habits of the animal; but as our limits will not permit its insertion, we refer the reader to the work, which is well worthy of his attention.

Sir William Jardine, in 'The Naturalist's Library,' vol. iii. (Ruminantia), speaking of the American elk, says, 'This is the only animal which will rank with the subgenus *Alces*, though to another animal, known only by the horns, the name of *coronatus* has been applied by Cuvier. They are in the Paris Museum, bear sixteen snags, but are scarcely a foot in length: they stand about three inches asunder, and more on the forehead than in the common elk; and Mr. Smith thinks they must have been borne by an animal not larger than the fallow deer, and states his opinion that it may prove to be the *Kistuke*, or little elk, of the Rocky Mountain Indians.'

Horns sessile, more or less divided, provided with basillary and median antlers.

*

Antlers flattened.

THE REIN-DEER.

Description.—The tame rhendeer, or reindeer, of the Laplanders, is, according to Hoffberg (*Amæn. Acad.*, vol. iv.), at the end of his back, an ell and a half high, and his length, from horns to tail, is two ells, whilst from the navel to the back-bone he measures three-quarters of an ell. On casting his coat, his hair is at first brownish-yellow, but as the dog-days approach it becomes whiter, till it is at last almost entirely white. Round the eye the colour is always black. The longest hair is under the neck; the mouth, tail, and parts near the latter are white, and the feet, at the insertion of the hoof, are surrounded with a white ring. The hair of the body is so thick that the skin cannot be seen when it is put aside, for it stands erect as in other animals of the same genus, but is much thicker. When the hair is cast it does not come away with the root, but breaks at the base.

The *horns* are cylindrical, with a short branch behind, compressed at the top and palmated with many segments, beginning to curve back in the middle, and an ell and a quarter long. A single branch, sometimes but seldom two, springs from each horn in front, very near the base, frequently equalling the length of the head, compressed at the top and branched. The distance between the tips equals the length.

The *horns* of the *female* are like those of the male, but less, more slender, and not so much branched: she has four true paps and two false ones.

The horns grow in the usual manner, and during the early part of their growth are extremely sensible, and suffer from the clouds of gnats (*Culex pipiens*) that form one of the persecutions of both deer and owner. About autumn, before rutting-time, they are become hard, and the velvet is rubbed off. Towards the end of November the male loses his horns, but the female retains hers till she brings forth; if barren, she drops them in the beginning of November.

When castrated, the reindeer seldom sheds his horns till the new year; the strongest shed them soonest, and the longer they keep them the worse they are. If Hoffberg is correct, Scheffer and Hulten, whose assertion he notices, are in error when they state that the castrated reindeer never loses his horns; and as the female, as well as the male, is furnished with them, this species may differ in that respect from others where the possession of those weapons is confined to the male.

The nostrils are oblique and oblong; their hoofs are large in proportion, and the cleft is hollowed internally, so that

the parts may touch accurately at the dividing line at the bottom; the tail is about a quarter of an ell, hardly so much.

The wild rein-deer grows to a much larger size than those which are tamed.*

It must be remembered by zoologists, that the horns of different individuals vary so much, that it has been asserted that no two, even of the same age and sex, have those weapons shaped exactly alike. Cuvier in his 'Ossemens Fossiles' has figured a series of the almost endless modifications of these horns from specimens in the Paris Museum; and the conclusion to which he came from these data is, that there is no character common to the whole species, but that of having the horns smooth and compressed in every part, except in the short portion immediately connected with the burr: that great zoologist has thus furnished the information that enables us to strike out several so-called species founded on this variety in the development of the rein-deer's horn.

The rein-deer is also subject to great variety of colour, particularly in a domesticated state, as is the case with most other animals; and spotted or mottled individuals are by no means uncommon in Lapland, and are of still more frequent occurrence in Siberia.

[Heads of two old buck Caribou of the Barren Grounds. From Dr. Richardson's cuts taken from Captain Back's drawings.]

It has been a question with some whether the *Lapland Rein-deer*, and *The Caribou*, or *Rein-deer of America*, and its varieties, are distinct species. Colonel Smith remarks, that a probable distinction, by which some, if not all, the varieties of *Caribou* may be distinguished from the rein-deer of the Old Continent is, that their horns are always shorter, less concave, more robust, the palm narrower, and with fewer processes than those of the former. This is another instance of the danger of relying on the form of the

* The memoir is supposed to have been published by Linnæus under the name of his pupil.

horns in this sub-genus as a distinguishing character. 'I have had but little opportunity,' says Dr. Richardson, in his *Fauna Boreali-Americana*, 'of ascertaining how far these remarks apply to the woodland variety of Caribou; but I can with confidence say, after having seen many thousands of the Barren Ground kind, that the horns of the old males are as much, if not more palmated than any antlers of the European rein-deer to be found in the British museums.' The annexed cuts were made from drawings by Captain Back, of the antlers of two old buck Caribou, killed on the Barren Grounds, in the neighbourhood of Fort Enterprise. It is to be recollected, however, that the antlers of the rein-deer assume an almost infinite number of forms, no two individuals having them alike.

It is, then, the general opinion among zoologists, that the American, European, and Asiatic races of rein-deer, are varieties of one species, of which the following appear to be the

Synonyms.—*Rangifer*, *Reinther*, and *Tharandther*, of Gesner and others; *Tarandus*, of Aldrovandus and others; *Cervus mirabilis*, *Cervus palmatus*, *Rangifer*, *Reinther*, *Tarandus*, *Tarandther*, of Jonston; *Caribou*, ou *Asne Sauvage*, of Sagard-Theodat, La Hontan and Charlevoix; *Carré-bœuf*, or *Caribou*, of the French Canadians; *Cervus Tarandus*, of Linnæus, Sabine, Richardson, Ross, Harlan, and James Clark Ross; *Rein-deer* or *Rain-deer*, of Drage, Dobbs, Pennant, Cartwright, Franklin, Godman, and James Clark Ross; *Rein-deer*, or *Caribou*, of Richardson; *Attehk*, of the Cree Indians; *Etthin*, of the Chippeways and other Northern Indians; *Tooktoo*, of the Esquimaux (Richardson); *Tukta*, of the Greenlanders (Fabricius); *Rhen*, of the Swedes; *Rhenne*, of the French; *Boetsoi*, of the Laplanders; *Common Deer*, of Hearne, Parry, and Lyon (Richardson); *Rhen-deer* and *Rein-deer*, of the English.

Var. *a*. *Arctica*. Barren Ground Caribou (Richardson).

Common Deer, of Hearne; *Bedsee-awseh*, of the Copper Indians and Dog-Ribs; *Bedsee-choh* (male), *Tsootai* (female), *Tampek* (female with a fawn), of the same; *Took-too*, of the Esquimaux, *Took-Took* dual, *Took-Toot* plural (Richardson); *Tukta*, of the Greenlanders (*Pangnek*, male; *Kollowak*, female; *Norak*, young. Fabricius).

Var. *β*. *Sylvestris*. Woodland Caribou (Richardson).

Caribou, of Theodat, La Hontan, Charlevoix, &c.; *Rein-deer*, of Drage, Dobbs, &c.; *Attehk*, of the Cree Indians; *Tantseeah*, of the Copper Indians (Richardson).

Geographical Distribution.—Northern Europe, Asia, and America. Captain James Clark Ross, in the Appendix to Sir John Ross's last voyage says, that although this animal was seen in great numbers on the Isthmus of Boothia, only one individual was killed in the course of their late voyage. It was a fine buck, of larger size than ordinary, and weighed 250 lbs.; the average of those killed at Spitzbergen and Melville Island did not exceed half that weight. The does arrive about the middle of April, the bucks nearly a month later; and herds of several hundreds were seen about the isthmus towards the end of May. Although they migrate towards the middle of September to milder climes, yet stragglers are occasionally seen in the winter. They are, indeed, spread, as Mr. Bennett observes, 'abundantly through all the habitable parts of the Arctic regions and the neighbouring countries, extending in the New Continent to a much lower latitude than in the old, and passing still farther south on all the principal mountain chains. In America, the southern limit of the rein-deer across nearly the whole continent appears to be about the parallel of Quebec; but the animal is most numerous between 63° and 66°. Passing westwards, it is said to be unknown in the islands interposed between America and Asia, but is again abundant in Kamtschatka, throughout nearly the whole of Siberia, in Northern Russia, Sweden, and Norway, and more especially in Finmark and Lapland. In these latter countries the numbers of the few wild herds that still exist are suffering a constant diminution, every art being put in practice by the hardy natives to reclaim and domesticate an animal which constitutes their sole property, the source of all their comforts, and the very means of their existence; without which their land would actually be, as at a first glance it seems, a bleak and uninhabitable desert. According to M. Cuvier, the Baltic forms in Europe its southern limit; in Asia, however, it extends along the Ural chain to the foot of the Caucasus; and we

have the authority of a passage in Cæsar's Commentaries, which can scarcely apply to any other animal, for its having existed in his day in the Hercynian Forest. The boundaries of this immense tract of woodland are certainly not very well defined; but this location would imply, at all events, a more southern European habitat than any that is at present known. Again, crossing the ocean, we find the rein-deer at Spitzbergen in Greenland, and in Newfoundland; but it has been said by Pennant, and this has been lately repeated by Dr. Richardson, in his valuable zoology of the fur countries of North America, not to be known in Iceland. This statement, which was scarcely true at the time when Pennant wrote, is not by any means correct, as refers to the present day. About sixty years since, as we learn from Van Troil's Letters on Iceland, thirteen of these animals were imported from Norway, ten of which dying on the passage, only three were landed. These were turned out into the mountains, and have since multiplied to such an extent, in the interior and unfrequented parts of the country, that their progeny was estimated by Count Trampe, the governor, in 1809, the period of Dr. Hooker's visit, at no less than five thousand head. Herds of forty, sixty, or even a hundred individuals are said, both by Dr. Hooker and by Sir George Mackenzie, who visited the island in the following summer, to be not uncommon in the mountains. They are, however, of little use to the inhabitants, who have made no attempts to domesticate them, and are too poor to purchase powder and ball for their destruction. It does not appear indeed that they are much sought after, the cow and the sheep thriving extremely well upon the island, and supplying the place of the deer in almost every respect. We may add that, according to Mr., (now Sir Arthur) Brooke, an importation of six bucks and twenty-four does took place in 1777, about seven years after the period of the first introduction of the animal into Iceland. (*Gardens and Menagerie of the Zoological Society*, vol. i.)

The size of the rein-deer, widely spread as it is, varies very much according to the accidents of climate; and if authors are to be credited, their weight ranges from 60 to 400 lbs. The latter is probably an exaggeration, but it is evident that the weight increases in proportion to the proximity of the animal to the Pole. According to Dr. Richardson, the bucks of the variety called *The Barren-ground Caribou* weigh, exclusive of the offal, when in good condition, from 90 to 130 lbs., whilst he describes the *Woodland Caribou* as much larger; and Captain, now Sir John Franklin, makes the weight of the latter from 200 to 240 lbs. The buck killed on the Isthmus of Boothia was, as we have seen, 250 lbs.; while the average of three killed at Spitzbergen and Melville Island did not exceed half that weight. The rein-deer of Norway and Sweden are diminutive when compared with those of Finmark and Lapland, which in their turn yield to those of Spitzbergen; and these again fall short of the more Polar races. The sledge-deer of the Laplanders is small, when compared with those reared by the Tungusians of the north of Asia, who ride upon them.

Food, Habits, Chace.—The food of the rein-deer varies with the seasons and the climate. Lapland, says Hoffberg, in the memoir above quoted, is divided into two tracks, called the alpine and woodland country. Those immense mountains, called in Sweden Fjellen, divide that country from Norway, extending towards the White Sea as far as Russia, and are frequently more than twelve miles in breadth. The other, called the woodland division, lies to the east of this, and differs from the neighbouring provinces of Norway by its soil, which is exceedingly stony and barren, being covered with one continued tract of wood, of old pine-trees. This tract has a very singular appearance. The trees above are covered over with great quantities of a black hanging lichen, growing in filaments resembling locks of hair, while the ground beneath appears like snow, being totally covered with white lichens. Between this wood and the Alps lies a region called the Woodland, or Desert Lapmarc, of thirty or forty miles in breadth, of the most savage and horrid appearance, consisting of scattered uncultivated woods, and continued plains of dry barren sand, mixed with vast lakes and mountains. When the mosses on part of this desert tract have been burnt, either by lightning or any accidental fire, the barren soil immediately produces the white lichen which covers the lower parts of the Alps. The rein-deer in summer seek their highest parts, and there dwell amidst their storms and snows, not to fly the heat of the lower regions, but to avoid

the gnat and gad-fly. In winter these intensely cold mountains, whose tops reach high into the atmosphere, can no longer support them, and they are obliged to return to the desert and subsist upon the lichens. Of these its principal food is the rein-deer lichen. There are, says Hoffberg, two varieties of this; the first is called *sylvestris*, which is extremely common in the barren deserts of Lapland, and more particularly in its sandy and gravelly fields, which it whitens over like snow; its vast marshes, full of tussocks of turf, and its dry rocks are quite grown over by it. The second variety of this plant, which is less frequent than the former, is named the Alpine; this grows to a greater height, with its branches matted together: it has this name, because when those mountains are cleared of their wood the whole surface of the earth is covered with it; yet it is seldom to be found on their tops. When the woods become too luxuriant the Laplander sets fire to them, as experience has taught him that when the vegetables are thus destroyed, the lichen takes root in the barren soil and multiplies with facility; though it requires an interval of eight or ten years before it comes to a proper height. The Laplander esteems himself opulent who has extensive deserts producing this plant exuberantly: when it whitens over his fields, he is under no necessity of gathering in a crop of hay against the approach of winter, as the rein-deer eats no dried vegetable, unless perhaps the river horsetail (*Equisetum fluviatile*). They root for this lichen under the snow like swine in a pasture; their foreheads, nose, and feet are guarded with a hard skin closely attached to those parts, that they may not be hurt by the icy crust which covers the surface of the snow. The very strong shoes which the Laplander esteems so much are made of these parts of the hide. It sometimes happens (but very rarely) that the winter sets in with great rains, which the frost immediately congeals; the surface of the earth is covered with a coat of ice before the snow falls, and the lichen is entirely encrusted and buried in it: thus the rein-deer is sometimes starved, and a famine attacks the Laplanders. In such an exigence they have no other resource but felling old fir-trees grown over with the hairy liverworts. These afford but a very inadequate supply even for a small herd, but the greater part of a large one, in such a case, is sure to perish with hunger. In the summer, when the rein-deer ranges upon the Alps, a number of plants afford it food. Hagstrom states that it refuses to eat forty-six species, the names of which he gives. Dr. Richardson states that the *Barren-ground Caribou*, which resort to the coast of the Arctic sea in summer, retire in winter to the woods lying between the 63° and the 66° lat., where they feed on the *Usneæ*, *Alectoriciæ*, and other lichens which hang from the trees, and on the long grass of the swamps. About the end of April, when the partial melting of the snow has softened the *Cetrariæ*, *Corniculariæ* and *Cenomyces*, which clothe the Barren Grounds like a carpet, they make short excursions from the woods, but return to them when the weather is frosty. In May the females proceed towards the sea-coast, and towards the end of June the males are in full march in the same direction. At that period the sun has dried up the lichens on the Barren Grounds, and the caribou frequent the moist pastures which cover the bottoms of the narrow valleys on the coasts and islands of the Arctic sea, where they graze on the sprouting *carices* and on the withered grass or hay of the preceding year, which is at that period still standing and retaining part of its sap. Their spring journey is performed partly on the snow, and partly, after the snow has disappeared, on the ice covering the rivers and lakes, which have in general a northerly direction. Soon after their arrival on the coast the females drop their young; they commence their return to the south in September, and reach the vicinity of the woods towards the end of October, where they are joined by the males. This journey takes place after the snow has fallen, and they scrape it away with their feet to procure the lichens, which are then tender and pulpy, being preserved moist and unfrozen by the heat still remaining in the earth. Except in the rutting season, the bulk of the males and females live separately; the former retire deeper into the woods in the winter, whilst herds of the pregnant does stay on the skirts of the Barren Grounds, and proceed to the coast very early in the spring. Captain (now Sir William) Parry saw deer on Melville peninsula as late as the 23rd of September, and the females with their fawns made their first appearance on the 22nd of April. The males in general do not go so far north as the females. On

the coast of Hudson's Bay the *Barren-ground Caribou* migrate further south than those on the Coppermine or Mackenzie Rivers, but none of them go to the southward of Churchill. The lichens on which the Caribou principally feed whilst on the Barren Grounds are *Cornicularia*, *tristis*, *divergens*, and *ochroleuca*, *Cetraria*, *nivalis*, *cutellata*, and *Islandica*, and *Cenomyce rangiferina*. (Fauna Boreali-Americana.) In the Isthmus of Boothia the reindeer does arrived about the middle of April, the bucks nearly a month later; and herds of several hundreds were seen about the isthmus towards the end of May. Numbers of the fawns, which at that period are in a very weak state, are killed by the natives, who hunt them with their dogs; and the does themselves often fall victims to their attachment to their offspring. Captain James Ross states that the reindeer feeds on the *Usnea*, *Alectorica*, *Cetraria*, and other lichens, in the early part of spring; but as the summer advances the young and tender grass fatten it so quickly, that in August they have been killed with several inches thick of fat on their haunches. In this state the meat is equal to the finest English venison, but is most tasteless and insipid when in poor condition. (Appendix to Sir John Ross's *Last Voyage*.)

That the lichen is not absolutely necessary as an article of food to the reindeer, was proved by the length of time during which a female of the white variety lived at the gardens of the Zoological Society of London in the Regent's Park. She lived and thrived through two successive winters, and died in 1830. Her food was principally dry provender, for the small quantity of grass which she could have cropped in the same small inclosure wherein she was always kept, must have been very small. The report drawn up by Mr. Yarrell on the morbid appearances, stated inflammation of the brain, lungs, and small intestines, which existed in a small degree in the latter. The mesenteric glands were diseased, but not to the extent that might have been expected in an animal that had been many years in an artificial state. The reporter stated that he had no doubt that the inflammation of the lungs was the primary cause of death.

Whilst on the subject of the food of the reindeer, we must not omit the propensity (a morbid one probably) attributed by Sir Arthur Brooke to the reindeer of eating lemmings (*Hipudæus Norvegicus*, *Mus Lemmus*, Linn.) not habitually, but accidentally. The lemmings, it should be remembered, are said to feed on the *rein-deer lichen*. Captain Franklin mentions an analogous propensity in the American reindeer, which, he says, 'are accustomed to gnaw their fallen antlers, and are said to devour mice.' The gnawing of the fallen antlers may be to correct acidity, as a cow may frequently be seen to gnaw bones for the same purpose.

Our limits will not allow us to detail the different modes of hunting the reindeer, however interesting the subject may be: suffice it to say that the caribou travel in herds varying in number from eight or ten to two or three hundred; their daily excursions being generally towards the quarter from which the wind blows, and that the Indians kill them with bows and arrows or guns, sometimes approaching by means of a disguise, sometimes taking advantage of rocks or other shelter, and always greatly assisted by the curiosity and unsuspecting nature of the deer themselves. They also take the reindeer in snares, or spear them as they are crossing rivers or lakes. The Esquimaux take them in traps ingeniously formed of ice and snow. A single family of Indians will sometimes destroy two or three hundred in a few weeks; and in many cases they are killed for the sake of their tongues alone. The reader will find a graphic account of the Esquimaux method of taking them in Captain Lyon's 'Private Journal,' p. 336; and a description of the deer found in use among the Chepewyans (Chipewyans), in Hearne. Captain Franklin relates the ingenious methods pursued by the Copper Indians and Dog-Ribs. Captain James Ross remarks that the natives of Boothia seldom hunt the reindeer in the spring, and then the bow and arrow is the only mode of killing it; but in the autumn, as the animal returns from the north in fine condition, they are destroyed in great numbers by parties of the natives driving them into the water, whilst others in canoes kill them with spears at their leisure. (Appendix to Sir John Ross's *Last Voyage*.)

Utility to Man.—To the Laplander particularly, the reindeer is all in all. According to Hoffberg, the mountaineer very often possesses three or four hundred, or even a thou-

sand head; the woodman very rarely above one hundred. As a domestic animal, yielding a quantity of the most delicious food, and occupying the place of the cow and the ox, it is invaluable. As a beast of burthen, its importance is equally great, and its organization is adapted to the icy wastes, over which it forms the Laplander's sole medium of communication, no less than that of the camel is framed for those arid deserts which, without the latter animal, would be impassable. The domestic economy of the Laplanders, as depending on the reindeer, is a most interesting subject, to which we can here only advert, referring the reader for information on the subject to Hoffberg's interesting paper on the subject above quoted; to Sir Arthur de Capell Brooke's *Winter in Lapland*; and to the 1st vol. of *The Menageries*, published by the Society for the Diffusion of Useful Knowledge, for details. The well-known and beautiful lines of Thomson, ('Seasons—Winter') are no fiction, but a true summary of the benefits of this most useful animal. The weight which it can draw when harnessed to a sledge is said to be 300 lbs.: but 240 lbs. form the general limit of the burthen. The tales told of its swiftness, when thus employed, would appear almost incredible if not so well attested as they are. In a race of three deer with light sledges, started by Pictet, who went to the north of Lapland in 1769 to observe the transit of Venus, the first performed 3089 ft. 8 in. and $\frac{26}{100}$ in two minutes, making a rate of nearly 19 English miles an hour: the second went over the same ground in three minutes, and the last in three minutes twenty-six seconds. One is recorded to have drawn an officer with important dispatches in 1699, 800 English miles in forty-eight hours; and the portrait of the poor deer which fell dead at the end of its wonderful journey, is still preserved in the palace of Drottningholm, in Sweden. Journeys of 150 miles in nineteen hours are said not to be uncommon.

To the natives of North America the reindeer is only known as a beast of chase, but it is a most important one: there is hardly a part of the animal which is not made available to some useful purpose. Clothing made of the skin is, according to Dr. Richardson, so impervious to the cold that, with the addition of a blanket of the same material, any one so clothed may bivouack on the snow with safety in the most intense cold of an Arctic winter's night. The venison, when in high condition, has several inches of fat on the haunches, and is said to equal that of the fallow-deer in our best English parks; the tongue and some of the tripe are reckoned most delicious morsels. *Pemmican* is formed by pouring one-third part of melted fat over the pounded meat and incorporating them well together. The Esquimaux and Greenlanders consider the stomach or paunch, with its contents, a great delicacy, and Captain James Ross says that those contents form the only vegetable food which the natives of Boothia ever taste. For further particulars, and they are many and interesting, we must refer to Dr. Richardson's *Fauna Boreali-Americana*, and the works of our gallant northern voyagers generally.

[*Rangifer Tarandus.*]

Highly excellent as an article of food, and useful domestically as this animal is, we do not think that it can ever be introduced with much success into the British islands. Not that there would be much difficulty about the food for the deer; it is space that is wanting. A long succession of ge-

nerations would be required before the migratory habits of the rein-deer could be got rid of, and possessing as we do the best venison, and the finest breed of horned cattle and horses, there seems no very good reason for repeating the experiments which have already been tried and have failed.

* *

Upper antlers alone compressed.

THE FALLOW-DEER. (*Daims*, of the French.)

Example.—*The common Fallow-deer.* This well-known ornament of our parks is the *Hydd* (Buck), *Hyddes* (Doe), *Elain* (Fawn), of the antient British; *Le Daim* (Buck), *La Daim* (Doe), *Faon* (Fawn), of the French; *Daino* (Buck), *Damma* (Doe), *Cerbiotto*, *Cerbiotta* (Fawn), of the Italians; *Gama*, *Corza* (Buck), *Venadito* (Fawn), of the Spanish; *Corza* (Buck), *Veado* (Fawn), of the Portuguese; *Damhirsch*, of the Germans; *Dof*, *Dof Hjort*, of the Swedes; *Daae*, *Dijr*, of the Danes; *Dama vulgaris*, of Gesner; *Cervus palmatus*, of Klein; *Cervus platyceros*, of Ray; and *Cervus Dama*, of Linnæus.

It is not certain whether the common fallow-deer is the *πρόξ* of Aristotle. Buffon and others are of that opinion; but M. Camus, who seems very well disposed to coincide with such opinion if he could, gives good reasons for doubt. Pennant considers the *Platycerata* of Pliny (book xi., c. 37), and the *Eurycerata* of Oppian (*Cyneg.* lib. ii., lin. 293) to have been our fallow-deer.

Pennant, speaking of the two varieties, the spotted and the deep brown, says, on the authority of Collinson, that they were introduced into this country by James I. from Norway, where he passed some time when he visited his intended bride, Anne of Denmark, and he remarks (citing Llywd) that one of the Welsh names of the animal, *Geifr Danys*, or *Danish goat*, implies that it was brought from some of the Danish dominions. James, who observed their hardiness, brought them first into Scotland and thence to Enfield Chase and Epping, to be near his favourite palace, Theobalds. When Pennant wrote, they were, according to him, scarcely known in France, but were sometimes found in the North of Europe. In Spain, he observes, they are extremely large, and that they are met with in Greece, the Holy Land, and in China. For the two latter localities he quotes Hasselquist, who says he saw it in Mount Thabor, and Du Halde. Pennant goes on to state that, in every country except our own, these deer are in a state of nature unconfined by man; but they are, and for some time have been, confined in parks on the continent as they are in England. In Moldavia and Lithuania they are said to be found wild. Cuvier observes that they have become common in all the countries of Europe, and that they appear to have come originally from Barbary. In a note to his last edition of the

'*Règne Animal*' he states that since the publication of the second edition of his '*Ossemens Fossiles*' he had received a wild fallow-deer (*Daim*) which had been killed in the woods to the south of Tunis.

The species is so well known that a lengthened description of the animal, its habits, &c., would be needlessly occupying space in a work of general reference. Besides the varieties above mentioned, there are many others, as is generally the case with reclaimed or half reclaimed animals: one variety is milk-white. Pennant remarks that in the old Welsh laws a fallow-deer was valued at the price of a cow, or, as some say, a he-goat.

[*Dama vulgaris*.]

Y

Horns sessile, with the antlers, both basilar and median, conical.

THE TRUE STAGS *

*

Old continent and its islands.

Example.—*The Common Stag, or Red Deer*; *Carw* (Stag), *Ewig* (Hind), *Elain* (Young or Calf), of the antient British; *Le Cerf* (Stag), *La Biche* (Hind), *Faon* (Young or Calf), of the French; *Cervio*, *Cervia*, of the Italians; *Ciervo*, *Cierva*, of the Spanish; *Cervo*, *Cerva*, of the Portuguese; *Hirtz*, *Hirsch* (Stag), *Hind* (Hind), *Hinde Kalb* (Calf), of the Germans; *Hart* (Stag) and *Hinde*, of the Dutch; *Hjort*, *Kronhjort* (Stag) and *Hind*, of the Swedes; *Kronhjort*, *Hind*, *Kid* or *Hind kalv*, of the Danes.

[*Cervus Elaphus*.]

* N.B. Mr. Smith makes a subgenus of the True Stags under the name of *Elaphus*.

This noble species is doubtless the *ελαφος* of Aristotle, and was well known to the ancients generally. It is a native of the forests of the whole of Europe and Asia, where the climate is temperate. In England it is intimately blended with the old oppressive forest laws which valued the life of a man at less than that of a stag, and with some of our legends of deadly feud: Chevy Chase for instance. Of the hunting we could say much, and of the old southern and stag-hounds that were employed in the more dilatory pursuit, and of the gallant grey-hounds, especially those of the north, that were wont to pull it down, nor do we forget the tinchel, identified with rebellion. But we must not indulge in a treatise on the forest-laws or on wood-craft here, and shall only observe that in the south of England his Majesty's pack now stands alone. The stag-hounds that formerly roused the deer on the moors of the west of England, are at present dispersed: and if this noble sport is to be again enjoyed in Somerset and Devon, we fear some time must elapse before a pack can be got up. In Scotland it is the rifle of the deer-stalker principally that now brings the stag down.

The red-deer is so well known that we need not repeat here the description of the animal and its habits, which will be found in most books of natural history. It has canine teeth in the upper jaw. Of the size to which the species sometimes grow the following record will serve as an example: 'When I was at Invercauld,' says Pennant, 'Mr. Farquharson assured me that he knew an instance of one that weighed eighteen stone Scots, or three hundred and fourteen pounds, exclusive of the entrails, head, and skin.' The same author states that in the old Welsh laws a stag was valued at the price of an ox.

* *

New Continent.

Example.—*The Wapiti Stag*, of Pennant, Arctic Zool.; *Wewaskiss*, of Hearne; *Waskeesews*, or *Red-deer*, of Hutchins; *Red-Deer*, of Umfreville; *the Elk*, of Lewis and Clark; *the American Elk*, of Bewick; *Wapiti*, of Barton and Warden; *Le Wapiti*, of F. Cuvier; *the Wapiti* (*C. Strongyloceros*), of Smith; *Red-deer*, of the Hudson's Bay Traders; *La Biche*, of the Canadian Voyagers; *Wawaskeesho*, *Awaskees*, and *Moostosh*, of the Cree Indians (Richardson). It is also *Le Cerf du Canada*, of Cuvier, who makes it the *Cervus Canadensis*, of Gmelin (Buffon), and *C. Strongyloceros*, of Schreber; and *Cerf Wapiti*, of Lesson, who states it to be *Cervus Wapiti*, of Mitchell, and *Cervus major*, of Ord. It may be also the *Stag of Carolina*, of Lawson, but he describes it as 'not so large as in Europe, but much larger than any fallow-deer,' and he says they are always fat with some delicate herbage that grows on the hills, whereas the modern travellers describe the Wapiti as frequenting the savannahs or the clumps of wood that skirt the plains. There is hardly any doubt that it is the Stag of America (*Cervus major Americanus*) of Catesby. 'This beast,' says the author last named, 'nearest resembles the European red-deer, in colour, shape, and form of the horns, though it is a much larger animal, and of stronger make. Their horns are not palmated, but round, a pair of which weighs upwards of thirty pounds. They usually accompany buffaloes (Bisons), with whom they range in droves in the upper and remote parts of Carolina, where, as well as in our other colonies, they are improperly called elks. The French in America call this beast the *Canada Stag*. In New England it is known by the name of the *Grey Moose*, to distinguish it from the preceding beast (the true Elk), which they call the *Black Moose*.' Dr. Richardson states that it is without doubt the *Canada Stag*, of various authors, but, as M. F. Cuvier has observed, the want of a pale mark on the rump in Perrault's figure is sufficient to excite a doubt of its being the *Cervus Canadensis*, of that author. Indeed he does not think it at all improbable that this figure is that of the *Cervus Macrotis*, which may hereafter prove to be an inhabitant of Upper Canada.

Geographical Distribution.—Dr. Richardson says that this animal does not extend its range farther to the north than the 56th or 57th parallel of latitude, nor is it found to the eastward of a line drawn from the south end of Lake Winnipeg to the Saskatchewan in the 103rd degree of longitude, and from thence till it strikes the Elk River in the 111th degree. To the south of Lake Winnipeg he thinks it may perhaps exist farther to the eastward. He adds that they are pretty numerous amongst the clumps of wood that

skirt the plains of the Saskatchewan, where they live in small families of six or seven individuals, and that they feed on grass, on the young shoots of willows and poplars, and are very fond of the hips of the *rosa blanda*, which forms much of the underwood in the districts which they frequent.

Description.—Height at the shoulders $4\frac{1}{2}$ feet, more than a foot exceeding that of the common stag. All the upper parts and the lower jaw of a somewhat lively yellowish-brown; a black mark from the angle of the mouth along the side of the lower jaw; a brown circle round the eye. The first antlers depressed in the direction of the facial line. Neck, mixed red and black, with coarse black hairs descending from it like a dewlap, deeper in colour than the sides. From the shoulders to the hips French grey; a pale yellowish patch on the buttocks, bounded on the thighs by a black line; tail yellowish, $2\frac{1}{2}$ inches long, whereas it is nearly seven in the European stag. The hair of a mean length on the shoulders, the back, the flanks, the thighs, and the under part of the head; that on the sides and limbs shorter, but the hair is very long on the sides of the head posteriorly and on the neck, particularly below, where they form the kind of dewlap above alluded to. On the posterior and outer aspect of the hind leg there is a brush of tawny hair which surrounds a narrow long horny substance. Ears white within and clothed with tufted hair, externally of the same colour as the neighbouring parts. A naked triangular space round the larger lachrymal sinus near the inner angle of the orbit. Hoofs small. Like the common stag, the wapiti has a muzzle, upper canine teeth, and a soft tongue. The quality of the hair is brittle, and there is a short wool beneath it. Dr. Richardson thinks that the Crees give it the name of 'Stinking Head' on account of the large suborbital opening.

Habits.—Hearne gives them a character for stupidity surpassing that of all the deer kind. He says that they frequently make a shrill whistling and quivering noise, not very unlike the braying of an ass. Mr. Drummond, who saw many in his journeys through the plains of the Saskatchewan, informed Dr. Richardson that it does not bell like the English deer. F. Cuvier describes the cry as prolonged and acute, consisting of the successive sounds *a, o, u*, (French), uttered with so much strength as to offend the ear.

Utility to Man.—Dr. Richardson describes the flesh of the wapiti as coarse, and little prized by the natives, principally on account of the fat being hard like suet. It seemed to Dr. Richardson to want the juiciness of venison, and to resemble dry but small grained beef. Its hide, when made into leather after the Indian fashion, is said not to turn hard in drying after being wet, and in that respect to excel moose or rein-deer leather.

The velvety covering of the horns, according to the same author, shrivels and is rubbed off in the month of October, at the commencement of the rutting season, but the horns themselves do not fall until the month of March or April.

The pair shed by 'Monkey,' (one of the wapiti kept by the Zoological Society of London in the Regent's Park) on the 4th March, 1837, weighed 26½ lbs.

[Wapiti]

That the wapiti will live and thrive well and propagate in Great Britain, there is now no doubt; but grand as the appearance of the animal is, it is not probable that it will be bred here to any great extent on account of the inferior quality of its venison.

δ.

Horns sessile, branched, with a solitary basilar antler, without median antlers, and the upper antler ordinarily simple.

THE AXIS DEER.

Spotted Species.

Example.—*The spotted Axis*, "Αξίς, of the antients (Ctesias); *Cervus Axis*, of authors; *Axis maculatus*, of Smith.

Description.—Size and general form nearly resembling that of the common fallow-deer. The skin is at all times of a rich fawn colour spotted with white; but, as Mr. Bennett observes, it is only during the summer that any similarity exists in the colours of the two species, for the fallow-deer changes in winter to a uniform brown, while the axis retains its spotted livery throughout the year. Height at the shoulder two feet six or seven inches. The distribution of the spots varies in different individuals. The ground colour changes to nearly black along the back; the under parts are snow white. Flanks, sides, shoulders, hind quarters, and part of the neck, spotted as above mentioned. There is a broad dusky spot on the forehead, and a line of the same colour extends along the middle of the nose. The male has no canine teeth, nor has the female any horns; she is generally less in size than the male, and resembles him much in colour, but may be distinguished, it is said, by a white longitudinal line on the flanks. The young resemble the parents.

Geographical Distribution.—India and the larger islands of the Indian Archipelago; very abundant in Bengal and on the banks of the Ganges.

Habits, &c.—The axis haunts the thick jungles in the vicinity of water, and the British sportsmen hunt it under the name of the *Spotted Hog Deer*. It feeds in the night, and is timid, indolent, and mild, excepting when the females have young, and then the male is bold and fierce.

[*Cervus (Axis) Maculatus*.]

The axis is easily domesticated, and in England has propagated freely in captivity. The species has been kept with success both in menageries and open parks, to both of which its form and colour make it an elegant ornament.

* *

Spotless species.

Example.—*Cervus Hippelaphus*, of Cuvier; *Cerf noir du Bengale, ou Hippelaphe*, of F. Cuvier; *Cerf d'eau, ou Mejanganbanjoe*, of the Malays of Java, according to Duvaucel; *Rusa* or *Roussaitan* (Black Stag), of the Javanese and Sumatrans; *Rusa Hippelaphus*, *The Great Rusa*, of Smith.

Description.—Size and proportions about those of the common stag, but its hair is rougher and harder, and when adult, that of the upper part of the neck, of the cheeks and of the throat is long, and forms a sort of beard and mane.

In winter its colour is of a greyish brown more or less deep; in summer it is of a brighter and more golden brown. The croup is a pale yellow, and the tail is brown terminated by rather long hair.

Locality.—Supposed to be Bengal and Sumatra; probably the islands of the Indian Archipelago.

This is supposed to be the *Hippelaphus* of Aristotle; but G. Cuvier who once was of that opinion, seems in the last edition of his 'Règne Animal' to consider that another species, *Cervus Aristotelis*, Cuv., living in the north of India, is the animal alluded to by the Greek Zoologist.

[*Cervus (Rusa) Hippelaphus*.]

[Skull of *Cervus Hippelaphus*.]

ε.

Horns sessile, branched, with a median but no basilar antler.

N. B. A white line bordered with black cutting the end of the muzzle obliquely.

*

Of the Old Continent.

Example.—*The Roe*, or *Roebuck*, probably the *Δορκάς*, of Aristotle; *Iorcas* and *Dorcas*, of Oppian; *Caprea*, of Pliny (Book xi. c. 37); *Caprea*, *Capreolus*, *Dorcas*, of Gesner; *Capreolus*, of Ray and of Sibbald; *Cervus Capreolus*, of Linnaeus; *Cervus minimus*, of Klein; *Iurich* (male), *Iuricheli* (female), of the antient British; *Le Chevreuil*, of the French; *Capriolo*, of the Italians; *Zorlito*, *Cabronzillo montes*, of the Spanish; *Cabra montes*, of the Portuguese; *Rehbock* (male) *Rehgees*, of the Germans; *Radiur*, *Rabock*, of the Swedes; *Raedijs* *Raebuk*, of the Danes.

Description.—Length about 3 feet 9 inches; height before, about 2 feet 3 inches; behind, 2 feet 7 inches. Weight from about 50 to 60lbs. Length of horns from 8 to 9 inches; they are erect, round, and divided into three branches above; their lower part is deeply furrowed longitudinally. Those of a young buck in its second year are simple; in the third year a branch appears; the head is complete in the fourth year. In the winter the hair on the body is long, the lower part of each hair is ash-coloured, there is a narrow bar of black near the end, and the tip is yellow. On the face the hair is black tipped with yellow. The ears are

long, of a pale yellow on the inside, and covered with long hair. In summer the coat is short and smooth, and of a bright reddish colour. The chest, belly, legs, and inside of the thighs, are yellowish white; the rump is pure white, and the tail very short. On the outside of the hind leg, below the joint, is a tuft of long hair.

Geographical Description.—The Roebuck was formerly very common in Wales, in the north of England, and in Scotland, but at present the species no longer exists in any part of Great Britain, except in the Scottish Highlands. Such is the locality given by Pennant when he wrote; and he adds, that, according to Dr. Mouffet, it was found in Wales as late as the reign of queen Elizabeth, and in great plenty in the Cheviot hills, according to Leland, in that of Henry the Eighth. That, at one time, the Roe inhabited the southern parts of the kingdom is clear, if the information given to the Editor of the last edition of the *British Zoology* is correct, for that states the discovery of seven or eight horns of the Roe in the peat beds near Romsey, in Hampshire, together with the complete head of a beaver, with the teeth entire. In Ireland, the animal is not known. They are frequent in France, and are found in Italy, Sweden and Norway, and Siberia. Pennant, who gives these localities, says that the first that are met with in Great Britain are in the woods on the south side of Loch Rannoch, in Perthshire; the last in those of Langwal, in Caithness; but that they are most numerous in the beautiful forests of Invercauld, in the midst of the Grampians. They are still comparatively plentiful in Scotland. Sir James Carnegie not long ago had a battue, in which forty were killed. Sir William Jardine states, that, south of the Forth, it is now very rare, one or two wilder parks only possessing a few; but frequent traces of its former abundance are found in the border counties, remains and skeletons being almost yearly disinterred from most of the larger peat mosses: in the rugged woods of Westmoreland and Cumberland it still abounds. The same author speaks of its frequency in many European countries, Germany, Silesia, &c. (*Naturalist's Library*, Mammalia, vol. iii.)

Habits, &c. The Roe does not keep in herds, but only congregates in families in the lower coverts and less wild woods. The female goes with young five months, and produces two fawns at a birth, and these she conceals from the buck. They are said to live twelve or fifteen years, and to be able to reproduce the species at the age of eighteen months. Pennant observes, that it is a tender animal, and quotes Buffon, who says, that in the hard winter of 1709 the breed was almost extinguished in Burgundy, and many years passed before it was restored again. It is generally killed, either in the covert, or by the sportsman, who waits outside while the copse or wood is driven, with shot. It falls very readily, and often without being apparently severely struck: we have heard instances of their being knocked over with comparatively small shot. As soon as it is down the throat is cut, and the animal is hung up by the hind legs on the fork of some tree to bleed.

[*Capreolus Dorcas*.]

Food.—Herbage and tender shoots of underwood in the summer. They are said to be very fond of the *rubus saxatilis*, called in the Highlands the roebuck berry. In

winter, when the ground is covered with snow, they browse on the tender branches of the fir and the birch.—(Pennant.)

Utility to Man.—The flesh is delicate food when well-killed, and the horns are used for handles of couteaux, &c.

Pennant states that in the old Welsh laws a roebuck was valued at the same price as a she-goat.

**

New Continent.

Examples, the *Guazapuco* deer, *Mazama paludosa* of Smith, *Cervus paludosus* of Desmarest and Lichtenstein, *Guazú-pucú* of D'Azara: and the *Guazuti* of D'Azara, *Mazama campestris* of Smith, *Cervus campestris* of F. Cuvier and Desmarest, *Cervus leucogaster* ? of Schreber. The former is nearly as large as the common stag of Europe, and of a reddish-bay, excepting the inside of the ears, the lower part of the breast, and the inside of the limbs, which are white. A dark-brown stripe runs irregularly down the face on each side of the lips; the eyebrows and cheeks are paler, and the muzzle is large. Locality, the lower districts of Paraguay. The horns of the latter are more slender than those of the former, generally with two snags only, and the animal is much less than the *Guazapuco*, being hardly more than two feet six inches at the shoulder. It frequents the open plains, and is so swift, that D'Azara says that a horse cannot overtake it. He adds, that the venison of the young deer is delicate, but that the flesh of the old is strong. There is a legend that if the flesh be applied to a wound inflicted by the bite of a poisonous serpent it will cure it. There is nothing remarkable about the colours, which are distributed as in the majority of the *Cervidæ*; but it is said sometimes to vary almost to white.

ζ

Horns sessile, simple, and in form of a stiletto.

THE BROCKETS* (*Les Daguet*s) of the French, subgenus

Subulo of Smith.

Example.—The *Guazu-pita* of D'Azara, *Coassou* ? *Subulo rufus* (Pita Brochet) of Smith, *Cervus rufus* of F. Cuvier and Desmarest.

Description.—Height about twenty-nine inches; general colour reddish-brown; inside of ears (hairs short), space round the lips, lower part of head and tail, hind part of belly, buttocks, and inside of fore-legs to knees, whitish. Females without horns, nearly of the same reddish tint, with a white spot above the nose and on the upper lip.

Locality.—The low moist woods of South America, where it lives in large herds, and as ten females are seen for one male, it is supposed that their appearance gave currency to the report of a form of deer on the New Continent without horns. They are very fleet only for the first burst, for they are soon run down by dogs, and are sometimes captured by the lasso and balls.

[*Subulo rufus*.]

The *Guazu-bira*, *Cervus nemorivagus* of Lichtenstein, *Bira Roe* of Smith, is another example of this form. D'Azara seems to be the first who noticed it. This delicate little

* Bocket, Brochet, and Pricket are the terms applied to a young male deer with its first or simple horns.

deer is only twenty-six inches in length, and its aspect is said to approach that of the sheep, and to be less deer-like than that of the *Pita Brochet*. The ears are not so pointed at the extremity as those of the latter, and the lacrymal sinus is said to be nearly imperceptible.

Description. Lower part of head and lips whitish. Space round the eyes, inside of fore-legs, and from lower part of breast to buttocks, whitish-cinnamon. Neck and all the other parts brownish, approaching to greyish, each hair being tipped with white. Horns short. *Locality* the same as that of the *Guazu-pita*.

[*Subulo nemorivagus*.]

η

Horns supported on a long osseous pedicle rising from the os frontis.

THE CERVULES (*Cervules* of the French, *Styllocerus* of Smith.)

[Skull of Muntjak.]

Example.—*The Muntjak, Chevreuil des Indes* of Allamand. (Buffon, Dutch edition.)

Dr. Horsfield gives the following as the synonyms of this species. *Cervus Muntjak*, *der Muntjak*, Zimmerman, *Geographische Geschichte des Menschen und der vierfüßigen Thiere*, Leipzig, 1780. (From the communication of Pennant). *Cervus Muntjak*, *Cervus vaginalis*, Boddaert, 'Elen. Anim.' Rotterdam, 1785. *Cervus Muntjac*, Schreb., *Säugethiere*, Gmel., Fischer, *Zoognos.*, Shaw, *Gen. Zool.*; *Cervus moschatus*, *Cervus subcornutus*, Blainv., 1816, 1822; *Cervus Muntjak*? Raffles's Cat. Linn. Trans.; *Cervus Muntjac*, *Cervus Moschus*, Desm.

Description.—About one-fifth larger than the roebuck. Height at shoulders about two feet two inches; head pointed; eyes large, with lacrymal sinuses; ears rather large; tail short and flattened.

In the living animal there are on the face two rough folds of the skin, considerably distended and elevated, about an inch and a half apart above; and, following the direction of the prominent part of the forehead, they unite below, so as to mark the face with the letter V. In the dried subject the folds are contracted, and three distinct ribs appear,

which, observes Dr. Horsfield, suggested to Pennant the name of rib-faced deer. General colour reddish-brown above; belly and front of the thighs pure white. The male has large canines in the upper jaw; the female has none, nor has she horns.

Locality, Habits, Chase, &c.—Dr. Horsfield states that 'the Muntjak selects for its retreat certain districts, to which it forms a peculiar attachment, and which it never voluntarily deserts. Many of these are known as the favourite resort of our animal for several generations. They consist of moderately-elevated grounds, diversified by ridges and valleys, tending towards the acclivities of the more considerable mountains, or approaching the confines of extensive forests. Such districts are by no means uncommon in Java: they are covered with long grass, and shrubs and trees of moderate size, growing in groups or small thickets, and they generally intervene between cultivated tracts and the deep forests. Their vegetation is peculiarly adapted to afford to our animal a very abundant supply of nourishment: their surface is covered with long grass, *Saccharum spicatum*, well known to persons who have visited the interior of Java by the name of *Allang-Allang*, and the groves and thickets abound with *Phyllanthus Emblica*, Linn.: these two plants constitute its principal food. They also produce many species of *Hibiscus*, *Grewia*, *Urena*, and other malvaceous plants, all which are greedily eaten by the *Kidang*. About the middle of the dry season, in the Javanese winter, just before the foliage is renewed, the shrubs and herbaceous plants covering the plains and small woods are, according to an old and universal custom in Java, set on fire; and thus these tracts are prepared for a new vegetation, which appears shortly before the annual rains, in a period that may be compared with an European spring. After the lapse of a few weeks, the ground and shrubs are covered with fresh verdure, and a most abundant supply of food is ready for the *Kidang*. These districts, being in most cases sparingly supplied with water, do not invite an extensive population: the *Kidang* is not molested by a few solitary hamlets, but the leaves of the *Convolvulus Batatas*, and of many leguminous and cucurbitaceous plants, which always surround the dwellings of the natives, afford it an occasional repast. Many of these hamlets might be enumerated, which would afford a pleasant recollection to those persons who have visited the native courts, or the eastern capitals. Jebres, Kayu-urib, and Pring-ombo near Surakarta, and Kaliwungu near Samarang, are among the most favourite. The native inhabitants of the hamlets dispersed through the districts in which the *Kidang* is found, do not possess means to undertake the chase; but it affords amusement both to Europeans and natives of rank, who engage in it in different modes with great ardour. The *Cervus Muntjak* has a strong scent, and is easily tracked by dogs. When pursued, it does not go off, like the stag, in any accidental direction: its flight indeed is very swift at first, but it soon relaxes, and taking a circular course, returns to the spot from which it was started. The natives, acquainted with the character of our animal, describe it as possessing a great portion of craftiness, combined with much indolence. After several circular returns, if the pursuit be continued, the kidang thrusts its head into a thicket, and in this situation remains fixed and motionless, as in a place of security, and regardless of the approach of the sportsmen. If it remains unobserved, it is still unwilling to quit its haunts; and experienced hunters, acquainted with its natural disposition, after an unsuccessful pursuit, return the following day, and in many cases find the kidang near the same spot. The chase of the kidang, by means of dogs, affords occasionally a favourite amusement to the natives of rank in Java. Many of these, especially in the more distant provinces, keep large packs for this purpose, which are regularly trained. The dogs, vulgarly denominated pariahs, are the indigenous breed of the island, in a state of imperfect domestication: there are several varieties: one of these greatly resembles the Sumatran dog, of which a description, accompanied by a figure, is given by General Hardwicke, in the 13th volume of the Transactions of the Linnean Society: the body is lank, and the ears erect: they are ferocious in their disposition, and rarely show any attachment to their masters. The natives of Java, like other Mahomedans, entertain prejudices unfavourable to dogs: they rarely treat them with kindness, or allow them to approach their persons; and it is only in extraordinary instances, or when they contribute to their amusement, that they feed or care

for them: generally they are ill-treated, and left to provide for themselves, so that their famishing condition is disgusting to Europeans. Many of these dogs are extremely ardent and courageous in the pursuit of the kidang: when the chase commences, they are led with a line by an attendant to the spot: the peculiar exhalations soon discover the kidang; the dogs are discharged, and commence the pursuit with great ardour, while the sportsman follows more deliberately, and generally finds the dogs at bay with the kidang. The male animal possesses a great share of courage, and with its tusks makes a most vigorous defence: many dogs are wounded in the attack. The sportsmen uniformly are provided with remedies and applications, and by a simple suture attempt to unite those wounds which are not immediately fatal. In this operation they frequently succeed, and preserve their most valuable dogs; but in many cases the kidang makes fatal lacerations in the neck and breast, or lays open the abdomen. But although possessed of great courage, the life of the kidang is not tenacious, and the sportsman, on arriving at the spot, generally despatches it with small shot. The natives of the most distant districts are in the habit of bringing their best dogs to the capitals, on occasion of their half-yearly attendance, to perform the feudal services to the sovereigns, when their sports afford an occasional amusement to the European inhabitants. Other modes of chase are also employed by the natives of rank. One in particular is common in the western parts of the island: a district is surrounded by a line of hunters, and the kidang is driven in towards a central spot: forty or fifty animals are in this manner often obtained at a single pursuit. Many of the hunters are mounted, and the horses are trained to the chase. The sportsman endeavours to overtake the animal, and to kill it by a stroke with a sword. The inhabitants of Pugar and Blambangan, two provinces at the eastern extremity of Java, possessing a small population, but abounding in extensive plains and acclivities, which afford an ample range and abundant pasture to the kidang, are particularly skilled in this sport. The best horses are trained for it: the sportsman, without a saddle, mounts on the naked back, and carries on the pursuit with a frantic impetuosity at the risk of his limbs and neck. During my visit to these districts, I was frequently entertained by aged natives with narratives of their favourite sport, and of the dangers and accidents they had encountered on many occasions; but these had not diminished their ardour for this amusement. The native stag of Java is pursued in the same manner. In Banka a less arduous, but more destructive method is employed to take the kidang: a long rope of rattan is suspended, at a proper height above the ground, between two trees; numerous nooses, of the same material, hang from this, in a close and continued series, and the kidang, driven towards it, pursued by dogs and blinded by fear, does not perceive the slender rattan, and thrusting his head into a noose, is strangled on the spot. The kidang has other enemies and pursuers besides man: the tiger and leopard also approach its retreat, and many are annually destroyed by them. But in a mild cli-

mate a constant and regular supply of food abounds, and no great variation or decrease is observed in their number. The kidang is impatient of confinement, and is not fitted for the same degree of domestication as the stag. It is however occasionally found in the enclosures of natives and Europeans, but requires a considerable range to live comfortably: it is cleanly in its habits, and delicate in its choice of food. The flesh affords an excellent venison, which is often found on the tables of Europeans. The natives eat the males, and always present them in a conspicuous place in their feasts; but in consequence of some peculiarities in the habits of the females, they have an aversion to them as food.'

FOSSIL DEER.

The remains of deer are sufficiently numerous in beds of the third period of the tertiary series, and in caverns. Thus in the cave at Kirkdale Dr. Buckland found evidences of at least three species, the smallest being very nearly of the size and form of a fallow-deer, the largest agreeing in size with, but differing in form from, the elk, and a third of intermediate size, approaching that of a large stag or red-deer. The skeletons of animals found in the recent shell-marls of Scotland, according to Mr. Lyell, all belong to species which now inhabit or are known to have been indigenous in Scotland. Several hundred, he observes, have been procured within the last century from five or six small lakes in Forfarshire, where shell-marl has been worked. Those of the stag (*Cervus Elaphus*) are stated to be the most numerous; and if the others be arranged in the order of their relative abundance, they will follow, according to Mr. Lyell, nearly thus:—Ox, boar, horse, dog, hare, fox, wolf, and cat. The beaver, he adds, seems very rare; but it has been found in the shell-marl of Loch Marlie in Perthshire, and in the parish of Edrom in Berwickshire.

Remains of deer occur in other ossiferous caverns besides Kirkdale, as in Banwell cave, in the Muggendorf caverns, the Grotte d'Echenoz, and that on the banks of the Meuse, at Chockier; as well as in the osseous breccias of Gibraltar, Certe, Nice, Corsica, and Antibes. M. Bertrand de Doue found among the bones entombed in and beneath volcanic matter near St. Privat d'Allier (Velay) a large proportion of remains, referable to at least four undetermined species of *Cervi*, in company with *Rhinoceros leptorhinus* and *Hyaena spelæa*; and M. Robert extracted from the ferruginous beds at Cussac (Haute Loire) the bones of seven species of deer (to two of which he assigns the names of *Cervus Solihacus*, and *C. Dama Polignacus*), accompanied by the bones of the antelope, *Bos Urus* and *Bos Velaunus*, two species of horse, *Elephas primigenius*, *Rhinoceros leptorhinus* and *Tapir Arvernensis*. Among the fossil species enumerated we find, under section α , *Cervus giganteus*, *Cervus Euryceros*, and *Cervus Americanus*; under section β^* , *Cervus Guettardi*; and under β^{**} , *Cervus Hibernus*, and *Cervus Somonensis*.

Our limits will only allow us to draw the attention of our readers to this subject, and to the subjoined illustrations of the gigantic fossil elk, or rather stag. The skeleton is taken from that in the collection at Edinburgh, communicated by Professor Jameson to Cuvier. It was found in the Isle of Man, in a marl full of fresh-water shells, at the depth of eighteen feet. The dimensions are 'six feet high, nine feet long, and in height, to the top of the right horn, nine feet seven inches and a half.'

The skull and horns are taken from Cuvier's figure of the noble specimen deposited in the Paris Museum by Colonel Thornton.

Captain Proby Cautley, F.G.S., in his paper 'On the Remains of Mammalia found in the Sewalik Mountains, at the southern foot of the Himalayas, between the Sutluj and the Ganges,' enumerates, among the fine collection of bones found by him, those of the elk, and several varieties of deer. In the district between the Jumna and the Ganges he obtained the remains of more species of deer than one in the marl or clay conglomerate, described as consisting of fragments of indurated clay, cemented by clay, sand, and carbonate of lime. Professor Kaup discovered the bones of the following deer, *Cervi anocerus*, *trigonocerus*, *dicranocerus*, and *curtocerus*, in the sand resting upon the calcaire grossier in Rhenish Hesse, in company with *Dinotherium*, &c. &c. Deer therefore may be considered to have existed in the second and third tertiary periods, viz. the Miocene and Pliocene periods of Lyell.

[Mammalia]

Gigantic fossil Deer.]

[Skull and horns of the same.]

a, front view of the whole head; b, the skull seen from below; c, profile of the same; d, horn, on a less scale, seen perpendicularly to its posterior surface.

The remains of this extinct animal have been found in peat and marl in various parts of England and Ireland, in France, on the Rhine, in Silesia, and in Lombardy.

We have confined ourselves to a mere outline of this interesting and extensive family, and the student should consult for the species the works of G. and F. Cuvier, especially the 'Ossemens fossiles' of the former; of Mr. Hamilton Smith, in Griffith's Cuvier; of Lichtenstein (Saugethiere); and of Richardson (*Fauna Boreali-Americana*). He should also refer to the Proceedings of the Zoological Society of London; for, numerous as the species already are, new ones are daily occurring. Other works will occur to the learned, and we ought not to forget the Ruminantia, by Sir William Jardine (*Naturalist's Library*, 'Mammalia,' vol. iii., 1835), where much valuable information, ably illustrated, will be found.

DEFAMATION; the speaking slanderous words of another. The injured party may bring an action to recover damages, but to enable him to succeed, it is absolutely necessary that the words should contain an express imputation of some crime or misdemeanor which would make him liable to punishment; or, if the words are not actionable in themselves, some special damage should be proved to have resulted from them to the plaintiff. There are certain cases, however, where words are spoken of a tradesman or professional person in the way of his trade or profession, as that a tradesman is insolvent, or that an attorney deserves to be struck off the roll, in which the plaintiff, by reason of the character he fills, may recover damages. Of the first class a recent case affords an illustration. A churchwarden was accused by the defendant of having stolen one of the church bell-ropes: it was held that, as the property of the bell-ropes was vested in the churchwarden, the words did not impute a crime to the plaintiff for which he was punishable, and consequently that the action could not be maintained. In former times, actions for slander were very rare; and though it has been frequently said that actions for words spoken in heat or anger, suddenly and without deliberation, ought not to be encouraged, yet it has been truly observed (by Wray, Ch. Just.) that unless the party injured by false and malicious scandal had a remedy at law, it would lead to personal violence, and the consequences might be fatal. In most cases, malice in law may be inferred, but in actions for slander *prima facie* excusable on account of the cause of publishing the slanderous matter, malice in fact must be proved; it is scarcely necessary to observe, that where special damage is proved, the existence of malice is immaterial. Defamation is also punishable in certain cases by indictment and criminal information. Where the slanderous matter is spoken of a peer, the offence is termed scandalum magnatum, and is made punishable by various statutes: this mode of proceeding however may be said to have become obsolete.

The ecclesiastical courts have power to punish for defamation relating simply to spiritual affairs; as an imputation that the complainant is a heretic: but these courts can only inflict punishment by way of penance; they cannot award damages. An action may also be maintained for slander of title to an estate or property; but in this case the plaintiff must prove malice express or implied: it is not sufficient that the defendant should allege title in himself, or make objections to the title of the plaintiff if he had reasonable grounds for so doing. (Cowel; M'Culloch; Selwyn, *N. P.*) [**LIBEL**; **SLANDER**.]

DEFEAZANCE (from the French verb *défaire*, to make void), is an instrument which defeats the force or operation of some other deed, estate, or interest, upon the performance of certain prescribed conditions. Defeazances are of two kinds, the one applicable to freehold estates; the other, to terms of years and executory estates, and to recognizances, bonds, and other executory interests. The former must be a collateral deed made at the same time with that to be defeated, and forming part of the same transaction. In this manner mortgages were formerly made, the mortgagor enfeoffing the mortgagee, and at the same time executing a deed of defeazance. Defeazances have been discountenanced by the courts, as affording opportunities for fraud, and they are now rarely used as applicable to titles, it being far better to make the conditions apparent on the deed itself. (See lord Talbot's *Remarks in Ca. Temp. Talb.*, p. 64.)

The latter kind of defeazances may be made either at the time of the original transaction, or at any subsequent period:

it has been said that every defeazance must be made by deed; but other authorities have laid down that it need only be by means as high and solemn as the instrument to be defeated.

By the stat. 3 Geo. IV., cap. 39, defeazances to warrants of attorney and cognovits must be written upon the same paper or parchment as the instruments themselves. (*Bl. Com.*; Sheppard's *Touchstone*; *Co. Litt.*)

DEFERENT, a circle or oval curve on which the centre of another oval moves, while a planet is supposed to move round the latter. The term is one of the **PTOLEMAIC HYPOTHESIS**. Thus the earth's orbit, to choose an example out of the modern system, is a deferent on which the moon's orbit is carried. But to make this example perfectly represent the sense in which the word was used by Ptolemy, we must suppose the system of Tycho Brahé to be the real one, and a spectator in the sun assuming the Copernican system.

DEFFAND, MARIE DE VICHY, MARQUISE DU, daughter of Gaspard de Vichy, Count of Champ Rond, was born in 1696. She was brought up to figure in the world, according to the received expression; that is to say, to shine in the saloons of the capital. She had natural parts, wit, playfulness, and taste, which her education tended to stimulate, rather than to form her heart. In 1718 she married the Marquis du Deffand, a colonel, and afterwards general, in the French service. Having some time after separated from her husband, she had her own establishment, her parties, her admirers, and her petits soupers. She lived like many other ladies of rank and fashion of the times of the Regency and of Louis XV., and her correspondence throws much light on the manners of that age. She numbered among her friends and correspondents some of the most distinguished men of France, such as President Hénault, Montesquieu, Marmontel, D'Alembert, Voltaire, &c. After the death of her husband, in 1750, in order to accommodate herself to her reduced income, she gave up her establishment, and took apartments in the external or extra-claustral part of the Convent of St. Joseph, in the Rue St. Dominique, where she spent the remaining thirty years of her life. She continued, however, her evening parties, which were in great repute for wit, pleasantry, and bon ton, and to which most foreigners of distinction who resorted to Paris were introduced. Being afflicted with blindness, she took as a companion and reader an unprotected young person, Mlle. de l'Espinasse; but she afterwards became jealous of her, and they parted; on which occasion Madame du Deffand quarrelled with D'Alembert also. She continued, though blind, to correspond with her friends, and especially with Voltaire and Horace Walpole, to a very advanced age. She died at St. Joseph, in September, 1780, in her 84th year. Madame du Deffand possessed some very valuable qualities: she had real wit and taste without affectation, and much tact and sound judgment whenever caprice or prejudice did not lead her astray. She had a quick perception of merit of every kind, and her house was always open to it: she had a horror of dogmatism, exaggeration, and pedantry: although a free-thinker, she never partook of that absurd fanaticism against religion which characterized some of the philosophic writers of the eighteenth century. Her judgment was too calm and sober not to perceive the inconsistency of philosophical intolerance; she even gave some good advice to Voltaire on this subject, and was one of the very few who spoke frankly to him. In her correspondence with Walpole she judges Voltaire rather severely. 'Correspondance de Madame du Deffand avec M. Walpole de 1766 à 1780, suivie de ses Lettres à M. de Voltaire de 1759 à 1775,' 4 vols. 8vo., Paris, 1810; and also 'Correspondance inédite de Madame du Deffand avec D'Alembert, Montesquieu, le Président Hénault, &c., suivie des Lettres de M. de Voltaire à Madame du Deffand,' 2 vols. 8vo., Paris, 1809, with a biographical notice.

DEFILADING, is that part of fortification the object of which is to determine (when the intended work would be commanded by eminences within the range of fire-arms), the directions or heights of the lines of rampart or parapet, so that the interior of the work may not be incommoded by a fire directed to it from such eminences.

If it be required, with a given height of parapet, to approach obliquely as near as possible to an eminence, the following process is adopted, the situation of the rampart or parapet at that extremity of the intended line which is farthest from the eminence being also given. A line is sup-

posed to be drawn from the commanding eminence, or rather from a point about eight feet above it, through another point which represents the crest or summit of the intended parapet at the given place, and to be continued till it intersects the natural ground in rear of that part of the line of parapet. This crest is considered as the vertex of a cone whose base is a circle, on the ground, having for its radius a line equal to the distance from the parapet to the rear extremity of the ground to be protected (which distance, however, must always be less than that of the intersection above mentioned). Then a line being drawn on the plan, from the point vertically under the given crest, parallel to a line drawn from the said intersection and touching the circle, will be the direction of the intended rampart or parapet, whose height must be everywhere equal to that which was given. By this construction all the lines of fire from the commanding eminence, and passing closely over the crest of the parapet, will be in a plane meeting the ground on that eminence, and touching the convex surface of the cone.

Again, if it be required, when the plan of the work is determined, to ascertain the heights of a rampart or parapet in different places, so that the interior may be protected from the fire of the enemy on a commanding eminence beyond, the relative heights of the principal inequalities of the ground with respect to some horizontal plane, technically called the plane of comparison, (which generally passes through the highest or the lowest point) must be found by the spirit level. An oblique plane, technically called the plane of site, must be imagined to touch the summit of the eminence in front, to pass above all the intermediate ground, and to meet that in rear of the work; then the relative heights, with respect to the plane of comparison, of the several points in the plane of site which are vertically above the inequalities before mentioned of the natural ground, must be computed, and the differences (which express the heights of the plane of site above the natural ground in such places) being added to the given height which the rampart or parapet is to have above the plane of site, the sums will express the heights to which the works are to be raised above the natural ground at the same places.

When the work is of small importance, the elevations of the parapets above the ground are generally determined by the eye—thus:—Pickets are planted in convenient places, chiefly at the angles of the intended work (the plan of which has been already traced on the ground,) and on the summit of the commanding eminence, the picket in this place being about eight feet high. The visual rays being supposed to proceed from the top of this picket to two or more points, which must be also eight feet above the ground, in rear of the work, the intersections of these rays with the pickets planted on the magistral or ground line of the work, will show the heights to which the parapet is to be raised at those places in order that the interior may be effectually protected.

A similar process is employed when it is required to protect the defenders of any parapet from the fire of the enemy on a commanding eminence in their rear; in which case it is frequently necessary to raise, in the interior of the work, a mass of earth, which is called a traverse or a parados, according to its situation.

DEFILE, in military writings, is a name given to any narrow way. Every piece of ground which, in consequence of local impediments, can be passed by a column only on a narrow front, is called a defile. Such are roads along valleys, between walls or hedges, or over dykes raised across marshes. Sometimes also the term is applied to a street in a village, and to the path over a small bridge.

DEFINITION (*definire*, to mark out a boundary,) is the process of stating the exact meaning of a word, by means of other words. From so boundless a subject, we can only select a very few points, such as have reference to the most common uses of the term. In the first place, it is evident that all definition contains a species of fallacy, if considered as an absolute determination of the meaning of words. *Quis custodiet ipsos custodes?* who shall determine the meaning of the words which make up the definition? The process of definition can never appear satisfactory unless it be considered as a transition from many words to the single term which it is agreed shall stand for their meaning, be that what it may. All attempts at absolute definition must end in confusion of ideas.

But at least, perhaps it may be said, the mathematical sciences are founded upon exactness of definition. Nothing is more common than this assertion coupled with another, namely, that these sciences depend entirely upon definitions. In a certain sense both are true, but that sense is not the most frequent meaning of them. The exactness of mathematical definition is not of arbitrary construction, but a consequence of the exactness of the notions which all men have, or may be made to have, upon the things which the words represent. There is no exactness in the fundamental definitions of mathematics, verbally considered, but only much confusion arising from the attempt to introduce conventional accuracy. The words 'straight line' carry with them their own meaning, and even explain the attempt which is made to explain them; for no one would easily guess what sort of line it is which 'lies evenly between its extreme points,' unless he were aware that it is a 'straight' line which these words attempt to describe.

Definition may be purely nominal, or it may be such a description of the thing defined as amounts to a statement of some one of its fundamental properties. The first we see in the words 'isosceles triangle,' the definition of which is a simple annunciation that we intend to use a Greek term. The second may be seen in the article CONCAVE AND CONVEX, in which the definition is made by means of an absolute mathematical property of the thing defined: the relative position of the spectator, the curve in question, and a straight line, do not enter into the notion which the words immediately suggest. The method of Euclid is to supply a rough and descriptive definition addressed to the common notion of the word, followed by an assumption of a mathematical property under the shape of an axiom. Thus a straight line is 'that which lies evenly between its extreme points;' while the real definition, or distinction between straightness and the contrary is contained in the axiom 'two straight lines cannot enclose a space.' Every attempt at mathematical definition, which does not rest upon the selection of a substantive property of the thing defined, to be the test of its existence, is either the mere substitution of words for words, or an attempt to make that mere substitution effect something more than lies in it to perform.

The conditions of a good definition are, 1, perfect axiomatic evidence that the property which is made the distinguishing test belongs to the object intended to be defined, and to nothing else; 2, entire separation of the part of the property, if any, which admits of being demonstrably connected with the notion defined, from that which contains the assumption; 3, the introduction of the definition in the proper place, namely, when the necessity for a new verbal representation has begun to appear.

DEFLAGRATION is a term employed to denote the sparkling combustion of substances without violent explosion: thus when nitre and sulphuret of antimony are mixed and ignited or thrown into a hot crucible, the combustion which occurs is of the kind termed deflagration.

DEFLECTION. A term applied to the distance by which a curve departs from another curve, or from a straight line; and also to any effect either of curvature or of discontinuous change of direction. It is used where any 'bending off' takes place, which is in fact the etymological meaning of the word.

DE FOE, DANIEL, the son of James Foe, a butcher in the parish of St. Giles, was born in London, in 1661. Of his youthful years we have nothing particular to relate. His father, who was a dissenter, sent him to a dissenting academy at Newington Green, where he remained four years. As the only education he received was at this time, we may conclude that he applied with considerable advantage. Different reasons have been assigned for his prefixing 'De' to the family name of Foe: the true cause of his doing so was probably a desire to conceal the lowness of his origin, and a belief that this addition would effect the object. De Foe first appeared as an author in 1683, when he published a political pamphlet on the war that was then carried on between the Austrians and the Turks. Two years afterwards, his aversion to James the Second and his government and his zeal for the maintenance of Protestantism induced him to enlist under the duke of Monmouth, whose rash and ill-concerted conspiracy was the cause of so many executions. Our author had the good fortune to escape the fate that numbers of his companions suffered. De Foe had for some years been engaged in

trade, first as a hose-factor and wool-dealer (in the prosecution of which latter branch of his business he is said by Wilson, in his 'Life and Times of De Foe,' to have made more than one voyage to Spain); he afterwards established, on the banks of the Thames, in the neighbourhood of Tilbury Fort, a manufactory of brick and pan-tiles, which, until then, had always been imported from Holland. The introduction of this manufacture was doubtless a considerable benefit to this country. De Foe, however, did not profit by it: his lively imagination, his ardent temper, his eager interest in politics, and fondness for literature, disqualified him for commercial matters. His circumstances became involved, and a commission of bankruptcy was taken out against him: his creditors, however, for whose payment he made the most honourable exertions, were all ultimately satisfied.

In January, 1687-8, he was admitted a freeman of the city of London; and in 1695 was appointed accountant to the commissioners for managing the duties on glass; a short-lived occupation, which he unfortunately lost in 1699, when the tax was suppressed. In the beginning of 1700 he published the 'True-born Englishman,' a pamphlet in answer to a libel on King William, which had been written by Tutchin. This defence pleased the king, who not only admitted the author to an audience, but bestowed on him the more substantial reward of a present of money. From the good-will that the king appeared to bear him, he had hopes of again obtaining some public employment; but these expectations were soon destroyed by the death of the king and the accession of Queen Anne. In the new reign he could expect no favours from the government; he had always been obnoxious to the house of Stuart and its adherents. This source of profit then being dried up, without much chance of its re-opening, he betook himself diligently to his pen, to which alone he could safely trust for his subsistence. He wrote with unwearied assiduity; but the loss of his patron, the king, was soon severely felt. By an ironical pamphlet, called 'The shortest Way with the Dissenters,' he gave bitter offence to many powerful bodies in the state. The high-church party resented it as a libel, and offered a reward for the apprehension of the author. The House of Commons (February 25, 1702-3) angrily resolved that this scandalous book should be burnt by the common hangman; and the secretary of state issued the following proclamation:—'Whereas Daniel De Foe, alias De Fooe, is charged with writing a scandalous and seditious pamphlet, entitled "The shortest Way with the Dissenters." He is a middle-sized spare man, about forty years old, of a brown complexion, and dark-brown coloured hair, but wears a wig: a hooked nose, a sharp chin, grey eyes, and a large mole near his mouth. Whoever shall discover the said Daniel De Foe to one of her Majesty's principal secretaries of state, or any of her Majesty's justices of peace, so as he may be apprehended, shall have a reward of 50*l*.: to be paid upon such discovery.' He was shortly after caught, fined, pilloried, and imprisoned. 'Thus,' says he, 'was I a second time ruined; for by this affair I lost above 3500*l*.' (Ballantyne's Mem. of De Foe, in Sir W. Scott's *Prose Works*, vol. iv.) During the time that he was confined in Newgate he wrote an ode to the pillory, and matured a scheme for 'The Review,' a paper exclusively written by himself, which for more than nine years he continued to publish twice or three times a week. After he had been a prisoner for more than a year, Harley, who was then secretary of state, interceded with the queen for his release, who at once sent money to his wife, who was in great distress, and, after some delay, paid his fine and set him at liberty. De Foe, once more free, took a house at Bury St. Edmunds, whither he removed with his wife and children, and recommenced his literary labours. The renewal of his former pursuits was attentively watched by his numerous enemies. It is stated that fictitious suits were now commenced against him, and that a scheme was projected to apprehend him as a vagabond while he was on a journey to Exeter, and to kidnap him for a soldier. In 1706 De Foe was recommended by Lord Godolphin to the queen as a fit and proper person to send to Scotland to promote the Union. This business being entrusted to him, he resided in Edinburgh until the end of 1707, when, returning to London, he wrote an account of the subject with which he had been engaged. For his services during this mission the queen granted him a pension, which political changes not long permitting him to enjoy, he was again compelled to gain his livelihood by

writing. The attacks in his political pamphlets now, a second time, got him into difficulties; for two papers, one entitled 'What if the Queen should die?' the other called 'What if the Pretender should come?' he was fined 800*l*., and, in default of payment, again committed to Newgate. His second was not so long as his first imprisonment; he was liberated by the queen in November, 1713.

After the death of Anne in 1714, his enemies so assailed him from every quarter, that he was compelled in self-defence to draw up an account of his political conduct, and of the sufferings he had endured. The continual attacks of his opponents so weighed upon his mind and depressed his spirits, that his health gave way, and an illness was brought on which terminated in an apoplectic fit. When he recovered, he continued to write, but thought it prudent to desert his old field of political satire and invective, and to enter upon a new one. To afford entertainment by tales of fiction was his present task, and he now put forth the first part of his inimitable 'Adventures of Robinson Crusoe,' which no story has ever exceeded in popularity. The merits of this work have been disparaged on account of its want of originality: 'but really the story of Selkirk, which had been published a few years before, appears to have furnished our author with so little beyond the bare idea of a man living on an uninhabited island, that it seems quite immaterial whether he took his hint from that or any other similar story.' (Walter Scott, *Prose Works*, vol. iv., p. 245.) The great success and profits arising from the first induced him to write a second and third part, each of which had less merit than its predecessor, the last being a mere book-making job. We have not space to enumerate the multitude of pamphlets and books which our author published. 'The Adventures of Captain Singleton,' 'The Fortunes of Moll Flanders,' 'The History of Colonel Jack,' 'The Fortunate Mistress,' 'The Memoirs of a Cavalier,' and 'The History of the Plague,' which were among the most popular of his works that succeeded 'Robinson Crusoe,' form only a small portion of his writings. His biographers, Chalmers and Wilson, have published catalogues of the writings of De Foe, but it is very probable that they are incomplete, and that many of his works which were only of a temporary interest have been lost.

De Foe died at the age of seventy, on the 24th of April, 1731 in the parish of St. Giles's, Cripplegate. He left a widow and several children, among whom was Norton De Foe, the author of 'Memoirs of the Princes of the House of Orange,' who is thus satirised in Pope's *Dunciad*:—

'Norton from Daniel and Ostræa sprung,
Bless'd with his father's front and mother's tongue.'

Sophia, the youngest daughter of Daniel De Foe, published two treatises on the Microscope. She married Henry Baker, a man of considerable learning.

De Foe's powers as a writer are of no ordinary stamp: we speak of his prose works; for his poetry, which scarcely deserves the name, is as such of no value whatsoever.

If he had been in affluent circumstances we have every reason to suppose that he would have written less, and that necessity alone made him a book-maker, and drove him continually to the printing-press. The disputes of the time afforded an inexhaustible fund of topics, and the violence of party spirit was displayed by all factions in pamphlets, which were the weapons of political warfare. To this style of writing De Foe had two reasons for applying himself; first, because it was the surest to meet with a ready sale, and to bring him in a pecuniary return; and secondly, because he was himself an eager politician. As a Whig, he opposed the House of Stuart; as a Protestant, he wrote against Catholicism; and as a dissenter, against the church. His attention, however, was not confined to the hackneyed topics of the succession and the church: he treated of finance, trade, and bankruptcy, as well as of the union with Scotland; and all this, independently of his *Review*, which contained articles on foreign and domestic intelligence, politics, and commerce. 'The fertility of De Foe,' says Sir Walter Scott, 'was astonishing. He wrote on all occasions, and on all subjects, and seemingly had little time for preparation on the subject in hand, but treated it from the stores which his memory retained of early reading, and such hints as he had caught up in society, not one of which seems to have been lost upon him.' (*Prose Works*, vol. iv., p. 247.) Of his *Review*, we believe no complete copy is in existence: however great was the interest that it excited during the time of its publication, it did not long survive its

author. But it is not for the class of writings that we have been speaking of, although they were of undoubted ability, that De Foe chiefly is and will continue to be celebrated; it is by his popular narratives that his great fame has been obtained. Of these we may reckon three kinds:—1st. The account of remarkable occurrences, as the *Journal of the Plague Year*, and the *Memoirs of a Cavalier*; 2nd. The account of mariners, privateers, thieves, swindlers, and robbers, as *Robinson Crusoe*, the piracies of Captain Singleton, the histories of Colonel Jack, Moll Flanders, and Roxana; 3rd. The descriptions of supernatural appearances, as the *Life of Duncan Campbell*, a *Treatise on Spirits and Apparitions*, the very degenerate third part of *Robinson Crusoe*, and the *Apparition of Mrs. Veal*.* The accuracy of De Foe's nautical knowledge may be attributed both to his residence in Limehouse, a district frequented by sailors, and to his intimacy with Dampier. His acquaintance with low life and the tricks of swindlers and prostitutes must have been gained during his imprisonments. His style is inelegant, but simple and expressive. The remarkable quality of his writings is, the appearance of reality that is given to fiction. By a particularity and minuteness of description which his skill prevents from being tedious, he increases the probability of his story, adds to its interest, and carries forward his reader. No author of imaginary tales has impressed so many persons with the belief that they have been reading a true rather than a fictitious narrative.

DEGREE OF LATITUDE, LONGITUDE, &c., and DEGREE OF THE MERIDIAN. [GEODESY.]

DEGREE OF ANGULAR MEASURE. [ANGLE.]

DEGREE OF AN EQUATION. The degree of an algebraical term is the number of letters which enter into it as factors. Thus x^2y^3 is absolutely of the fifth degree, but of the second degree with respect to x , and of the third with respect to y . The degree of an equation is the degree of its highest term.

DEGREE. [ARTS; UNIVERSITY.]

DEIFICATION. [APOTHEOSIS; CONSECRATION.]

DEIOTARUS, a tetrarch or prince of Galatia, or Gallo-Græcia, was the ally of Rome in the wars against Mithridates, for which he was rewarded by the grant of part of Pontus and Little Armenia, with the title of king given to him by the Roman senate. Cicero, during his government of Cilicia, became acquainted with him, and received assistance from him against the Parthians. In the civil war between Cæsar and Pompey, Deiotarus took part with the latter, and was in consequence deprived by Cæsar of part of his dominions. After Cæsar's return from Spain, Deiotarus was accused by his own grandson, Castor, of having attempted to assassinate Cæsar, while the latter was in Asia. Cicero pleaded before Cæsar in favour of his old friend ('*Oratio pro Rege Deiotaro*.') After Cæsar's death, Deiotarus recovered possession of his territories; he took part with Brutus against the triumvirs, but afterwards made his peace with the latter, and subsequently favoured Octavius against Anthony in his final struggle for the empire. Deiotarus was then very old, but the precise time of his death is not known. According to Dion (lib. 48), his grandson, Castor, succeeded to his dominions in Gallo-Græcia; according to others, he was succeeded by Amyntas.

[Coin of Deiotarus.]

British Museum. Actual Size. Copper. Weight, 170 grains.

DEIRA, one of the two kingdoms into which that of Northumberland was divided in the infancy of the Saxon government. Deira, whose capital was York, comprehended the country between the Humber and the Tyne. Bernicia, the other division of the kingdom of Northumberland, had its capital at Bamburgh, and comprehended the territory between the Tyne and the Forth. But historians differ greatly in their accounts of the precise limits of these two

* For an account of this very ingenious composition and its complete success, we refer our readers to Sir Walter Scott's interesting biography of De Foe, with which the whole history of the Apparition has been reprinted.

divisions. Archbishop Usher, in his *Britannicarum Ecclesiarum Antiquitates*, fol., Lond., 1687, p. 212, discusses the different statements of Alured of Beverley, Malmesbury, and other writers, concerning them. The kings of Deira were Alla, or Ælla, 559; Osric, 633; Oswin, 644; Adelwald, or Ethelwald, 652; Alfred, about 660. The two kingdoms of Deira and Bernicia were united and separated several times during the period comprehended within these dates. Under Edfrid, in 670, they were again and finally united as the kingdom of Northumberland, and so continued till Andred, or Eanred, in 810, submitted to the dominion of Egbert, king of Wessex, by whom the Saxon heptarchy is considered to have been extinguished. (Camd., *Brit. edit.* Gough, 1789, iii., 1, 68, 75; Henry, *Hist. Brit.*, 4to., Edinb., 1774, ii., 221; Rapin, *Hist. Eng.*, fol., 1732, i., 47 and seq.)

DEISM properly means belief in the existence of a God, but is generally applied to all such belief as goes no farther, that is to say, to disbelief of revelation. It is always applied dyslogistically, and frequently merely as a term of reproach. But the identical word, in its Greek form, *theist*, is not a word of disapprobation, and, consistently with established usage, may be appropriately applied as opposed to atheist, when the latter term is correctly used. For it must be observed that the term atheist has been not unfrequently employed in the sense of an unbeliever in Christianity, though at the same time professing theism.

DELAMBRE, JEAN BAPTISTE JOSEPH, was born at Amiens, Sept. 19, 1749. His course of study was at the gymnasium of his native town. His excellent disposition, great perseverance, and extraordinary memory, early attracted the notice of his teacher in the college, the poet l'Abbé Delisle; and the friendship commenced between Delisle and Delambre, while they stood in the relation of preceptor and pupil, was continued unabated during the remaining part of the poet's life; and Delambre used to express his obligations to that eminent man with great feeling to the latest period of his life.

Delambre was desirous of pursuing his studies in Paris, but his pecuniary means were inadequate to the expenses in which he would be necessarily involved by such a course. The influence of Delisle however procured for him an exhibition to one of the colleges which was in the gift of his native town, and which it has been commonly said was first founded by one of Delambre's own family. The time during which he was entitled to hold it having expired, and his family being unable to furnish him the requisite assistance to prolong the period of his studies, he was compelled to adopt some means of supporting himself. After more than a year of disappointment, indecision, and privation, he undertook the occupation of translating foreign works into French; and many such translations from the Latin, Greek, Italian, and English writers were executed by him during the first fifteen years after he left college. In addition to this employment, he gave lessons in languages to private pupils; and, by the combined emoluments of these labours, he was not only able to supply his small personal wants, but to make an excellent collection of the best authors in the several languages which he studied.

The parsimonious views of parents on the subject of education have been witnessed by every one whose life has been devoted to instruction, under circumstances similar to those of Delambre. Their continual importunity to men eminent in some one pursuit, whom they have employed, to undertake others with which they have little or no acquaintance, and this for the sake of diminishing the expense of education, is proverbial. It was this continual application to Delambre, who was distinguished both in the philological and philosophical departments of language, to teach mathematics, which induced him, at the age of twenty-five, to enter upon the study of the exact sciences. Most men would have been soon wearied of a pursuit so undertaken; and this would have been the case with Delambre, had his mental discipline been merely that of exercising the memory, which is unfortunately too much the tendency of the exclusive study of languages. Order and perseverance were distinguishing characters of Delambre's mind; and having, from professional motives, entered on the study of mathematics, and thereby become attached to their pursuit, he determined to pursue a regular course of study in these sciences. He entered the astronomical class of the College of France under Lalande, but not till he had carefully read the works of his master, and made many notes upon them, amounting almost to a commentary.

On one occasion, shortly after he joined the class, a passage from Aratus was required, which Delambre instantly supplied from memory. Lalande, ever alive to the importance of astronomical history, was immediately interested in Delambre; and it is probable that to this circumstance much of the future fame and labours of Delambre are to be attributed, as Lalande became immediately his friend, and henceforth considered Delambre as his fellow-labourer. Many of the most complicated calculations of Lalande were actually performed by Delambre; but though our author probably entered upon much of this drudgery for pecuniary considerations, he has given ample proof that the labour was far from a disagreeable one to him, by the tables which he himself subsequently published in later life.

During a short residence at Compiègne, which he made while he was a professed teacher of languages, he appears to have paid some attention to plane astronomy; and when he formed a friendship with Lalande, M. Dassy, in whose family Delambre was domiciled as tutor to his sons, was prevailed on by the astronomer to fit up a small observatory for his use. In this Delambre acquired some skill in the manipulation of his instruments, and also in the management of the formulæ which are used in the particular classes of data that the structure of instruments enables us to obtain. He then determined to devote his life to astronomy, and its history. The learning requisite for the history of astronomy he had already obtained, though he had probably at this time read comparatively few of the books, and none of the manuscripts, which so arduous a task entailed upon him; whilst of the incessant labour required by the study of astronomy as a science he had possibly little idea, and of the skill which his future practice gave him his share was also very small. His ardour and perseverance, however, surmounted all the obstacles that opposed his progress; and never did any man more completely illustrate the trite proverb, *labor omnia vincit*, than Delambre.

When in 1781 the discovery of the planet Herschel was exciting the deep attention of astronomers, Delambre undertook the formation of tables of its motion, being probably urged to this by the Academy of Sciences having proposed the determination of its orbit as the prize of the year. That prize was awarded to Delambre. He then undertook the construction of his solar tables, as well as tables of the motions of Jupiter and Saturn. Shortly afterwards he commenced his tables of the eclipses of Jupiter, which occupied him some years. When, at a sitting of the Academy, Laplace communicated to that body the results of his researches on the inequalities of Jupiter and Saturn, he determined on constructing complete tables of the motions of those two planets, founded on those results, but more especially of those of Jupiter. The utility of such tables to the navigator was a strong inducement to this undertaking, which he entered upon with great ardour, and completed in an almost incredibly short period, when we consider the great labour which they involved. His eclipical tables were presented to the Academy in 1792, as a competing paper for the prize on that subject which had been offered the preceding year; but he had been for several years engaged in their calculation. It is indeed very probable that the prize was offered to induce him to complete them, as it was well known that he was engaged in the preparation of such tables. Such, indeed, is well known to be the general practice of that body; and though it has occasionally done good, in bringing to a completion researches that might not so soon have been completed, it does this mischief,—that it almost cuts off all competition, and inevitably gives the prize to a single candidate, by allowing him the advantage of a long previous preparation for it. We cannot disapprove of the adjudication on this occasion, as Delambre's labours well merited the distinction; but we do not think the general practice calculated on the whole to do other than give *éclat* to the members of the Institute themselves or their immediate friends.

When the project of fixing a standard of length was acceded to by the governments of France and England, Delambre and Méchain were appointed to carry it into execution on the part of the former government, by measuring the arc from Dunkirk to Barcelona. This laborious undertaking was carried on during the horrors of the French Revolution, amidst almost every variety of difficulty and personal danger that can be conceived. Méchain dying during the progress of the work, the completion of it devolved wholly on Delambre. His perseverance, prudence,

and zeal, however, eventually overcame all obstacles; and after eight years of unceasing labour and anxiety, he obtained the measurements which constitute the data of the three volumes (1806-10) of his elaborate and invaluable work, *Base du Système Métrique Décimal*. The Institute of France, who had watched over its progress, decreed him the prize for the most valuable work on physical science which had appeared within the preceding ten years; and it is difficult to conceive that a single objection could possibly arise to the propriety of that decision.

Of the continuation of Delambre's arc by Biot and Arago from Barcelona to Formentera, this is not the place to speak at length; but it may be necessary to state that discrepancies which had long been observed in this latter arc have been recently found by Puissant to arise out of actual errors committed by these observers.

Delambre was chosen an associate of almost every learned body in Europe, and was appointed by the French government a member of the Bureau des Longitudes, and Secrétaire Perpetuel de l'Institut de France, and one of the directors of the University of France. During the twenty years that he filled this latter important and responsible post, his attention to its duties was unwavering, and his decisions remarkable for their justice and impartiality. His *éloges* of the deceased savans were indeed at the time considered somewhat strained as to praise; but they were at least kindly meant to the friends of the deceased, and were gratifying to the vanity of the nation. They were remarkable for purity of style and for the researches into the history of the subjects to which the eulogized member had devoted himself.

In 1814 Delambre was appointed a member of the council of Public Instruction, but was deprived of it in the following year. He was in Paris when it was taken by the allied armies; and shortly afterwards, writing to one of his friends, he says he worked with perfect tranquillity from eight in the morning till midnight in the continued hearing of the cannonade. Such self-possession for study under that tremendous attack, and such absence of interest in the result of the great struggle, to say nothing of indifference to personal danger, is what we confess ourselves unable to understand. In the midst of active exertion we may be fearless of personal danger; but Delambre was in his study, and professes to have felt not only perfectly calm, but to have been able to pursue his scientific labours for sixteen hours in the very midst of the cannonade. He escaped uninjured.

On the creation of the Legion of Honour, Delambre was constituted a member of that body; and soon after an hereditary chevalier, with a pension, as a reward for his scientific services; and finally, in 1821, he was created an officer of that body. In 1817 he was created a chevalier of the order of St. Michael.

The death of Delambre occurred in 1822, at the age of seventy-two. It was preceded by a total loss of strength and frequent and long-continued fainting fits, with the other symptoms of a constitution worn out by hard mental and bodily labour. He died as he had lived, calmly, and though not without great suffering, yet without a single complaint.

The writings of Delambre are exceedingly numerous. The following is a list of his separate works in the order of their publication:—

1. Tables de Jupiter et de Saturne, 1789.
2. Tables du Soleil, de Jupiter, de Saturne, d'Uranus, et des Satellites de Jupiter, pour servir à la 3me édition de l'Astronomie de Lalande, 1792.
3. Méthodes Analytiques pour la détermination d'un Arc du Méridien, 1799.
4. Tables Trigonométriques Décimales, par Borda, revues, augmentées, et publiées par M. Delambre, 1801.
5. Tables du Soleil, publiées par le Bureau des Longitudes, 1806.
6. Base du Système Métrique Décimal, 3 vols., 1806-10.
7. Rapport Historique sur les Progrès des Sciences Mathématiques depuis 1789. 1810.
8. Abrégé d'Astronomie, ou Leçons Élémentaires d'Astronomie Théorique et Pratique.
9. Astronomie Théorique et Pratique, 4to., 3 vols., 1814.
10. Tables Ecliptiques des Satellites de Jupiter, 1817.
11. Histoire de l'Astronomie Ancienne, 2 vols., 4to., 1817.
12. Histoire de l'Astronomie du Moyen Age, 1 vol., 4to., 1819.

13. *Histoire de l'Astronomie Moderne*, 2 vols., 4to., 1821.

14. *Histoire de l'Astronomie au Dix-huitième Siècle*, 1 vol. 4to., 1827, published under the care of Matthieu, and another promised, but not yet, that we are aware, published.

Besides these separate works, Delambre published a considerable number of memoirs in the collections of Petersburg, Turin, Stockholm, and Berlin, independently of those which appeared in the *Mémoires de l'Institut de France*. Also twenty-eight memoirs on different subjects, astronomy, geodesy, and astronomical history, in the *Connaissance des Temps* from 1788 to 1820. A list of these may be seen in Coste's indexes to that work for 1807 and 1822.

Any attempt to analyze the writings of Delambre would far exceed the limits which can be allowed in this Cyclopædia. It is sufficient to say they are well worthy of the praise which has been bestowed upon them, as they are not only all excellent in their kind, but throughout marked with an original mind, indicate the most devoted enthusiasm to their several subjects, and prove that their author combined the spirit of scientific inquiry with the feelings and habits of literature in a degree that the history of a single individual has hardly ever before or since exhibited.

DELAWARE, a river in the United States, rises in the State of New York, between 42° and $42^{\circ} 30'$ N. lat., and afterwards forms the boundary-line between New York and New Jersey on one side, and Pennsylvania and Delaware on the other side. It terminates its course of 305 miles about five miles below Newcastle in Delaware, about $39^{\circ} 30'$ N. lat., and $75^{\circ} 40'$ W. long.

The Delaware is formed by two branches, the northern, called the Oquago, the southern, the Papachton, both rising on the western declivity of the Catskill Mountains, at an elevation of at least 1500 feet above the sea, and hardly 30 miles from the tide-water in the Hudson river. Both branches flow in a west-south-west direction for about 50 miles, and unite on the boundary of Pennsylvania, the Oquago turning suddenly to the south-east. In the same direction the river, which is now called Delaware, continues about 60 miles to the junction of the Neversink river. Hence it runs in a south-western and southern direction to the junction of the Lehigh at Easton, 65 miles, where it again turns to the south-east. After a course of 35 miles in that direction to Bordentown, it resumes its south-western course to the place where it enters Delaware Bay, five miles below Newcastle. The tide ascends in this river 120 miles from its mouth to the rapids at Trenton. The frequent changes in its course are caused by four ridges of the Appalachian Mountains, through which the river breaks in an oblique line. Though in its course above Trenton it forms numerous rapids, no cataracts, in the true sense of that term, interrupt the navigation of this river, which at seasons of high water extends by both branches into the State of New York. Ships of the line may ascend to Philadelphia, where the tide rises five or six feet, and sloops as far as Trenton.

The importance of this river has of late been greatly increased by the discovery of extensive coal-beds near the sources of its two largest tributaries, the Lehigh and Schuylkill. The Lehigh joins the Delaware at Easton, and the Schuylkill five miles below Philadelphia. Though both these rivers, whose sources are between 1400 and 1500 feet above the sea, and whose course does not exceed 100 miles, are extremely rapid, a great portion of their course has been rendered navigable by dams and locks, so that the produce of the coal-mines can be brought down to Philadelphia.

The navigation of the Delaware river is united to that of Chesapeake Bay by the Chesapeake and Delaware Canal, which traverses the north-eastern angle of Maryland and the northern district of Delaware, and connects the Elk river with the Delaware, 45 miles below Philadelphia. This canal, which is fourteen miles long, is navigable for small sea vessels. Its profits have never been sufficient to repay the heavy expense of its construction, and have been further diminished by the rail-road from Newcastle in the State of Delaware to Frenchtown in Maryland. By the Union Canal the Schuylkill navigation is connected with that of the Susquehanna. On the east a canal unites the Delaware at Trenton with Amboy Bay, and consequently with the city of New York; another canal is to begin opposite the mouth of the Lehigh, to traverse the northern districts of New Jersey, and to terminate near the city of New York;

and the Lehigh canal connects the Delaware with the coal mines of Mauch Chunk on the Lehigh. (Darby; *Maps of the Society for promoting Useful Knowledge*.)

DELAWARE BAY extends in a north-west direction, between 39° and $39^{\circ} 30'$ N. lat., and $74^{\circ} 50'$ and $75^{\circ} 40'$ W. long. Its entrance between Cape May in New Jersey and Cape Henlopen in Delaware is from 15 to 16 miles wide. It afterwards grows wider, forming on the east a wide open bay between Cape May and Egg Island: it then gradually narrows, and is considered to terminate five miles below Newcastle, at the embouchure of the river Delaware. Its whole length is about 56 miles. Its low and sandy shores are without harbours even for small vessels.

DELAWARE, the second smallest state of the United States of North America, extends from $38^{\circ} 27'$ to $39^{\circ} 50'$ N. lat., between $75^{\circ} 10'$ and $75^{\circ} 40'$ W. long. It comprehends the north-eastern portion of the peninsula which lies to the east of Chesapeake Bay, and more than one-third of its surface, having an area of 2100 square miles, or somewhat more than the county of Norfolk.

The watershed of the peninsula runs nearly through its middle, along the western boundary-line of Delaware, but rather within it. In its northern portion Delaware is undulating, but perhaps it nowhere rises more than 100 feet above high-water mark; it gradually becomes more flat towards the Atlantic Ocean. Farther south it is an extensive flat, from which the small rivers ooze rather than flow to the Chesapeake Bay and the Atlantic. Some districts of the country towards the sea are marshy, and subject to inundations. At the southern extremity is the Cypress Swamp, six miles from east to west, and twelve miles from north to south, covered with trees, and containing about 50,000 acres: a part of it belongs to Maryland. The coast is low and sandy, and has no harbour except at the northern extremity along the banks of the river Delaware. Rehoboth Bay, formed by a long and narrow strip of sand, is too shallow to admit even small vessels. A breakwater is now constructing by the general government within Cape Henlopen, which is expected to form a good harbour. It is two-thirds of a mile in length, and twenty-two feet wide at the top. A dike half the length of the breakwater, and parallel to it, will protect it against the ice brought down the river.

The soil is in some places excellent, especially in the northern districts, but it is generally thin and sandy, though everywhere carefully cultivated. The principal articles of export are corn and flour. The forests are not extensive, but the Cypress Swamp and those in the northern district produce lumber. Bog-iron is found not far from the small river Brandywine. Fruits are produced in abundance.

The climate is in general healthy and mild, but much severer in the northern than in the southern district, though the two are hardly more than a degree from one another.

The population amounted according to the census of 1820 to 73,000, and in 1830 to 76,739, of whom 3305 were slaves. On Christiana Creek, towards the northern boundary, and on Brandywine Creek, are several mills for grinding corn, and on the latter river also iron founderies. Vessels are built at Wilmington.

Dover, the capital of the state, has hardly more than 800 inhabitants. Wilmington, at the junction of Christiana Creek and the Brandywine, has a population of 6628, and carries on a considerable trade in corn, flour, and timber. Newcastle has a harbour and 2463 inhabitants.

Delaware is divided into three counties, and sends two senators and one representative to Congress. The State legislature consists of a senate of nine, and of a house of representatives of twenty-one members; the members of the former are chosen for three years, and those of the latter annually, by those inhabitants who pay state taxes. The executive power is in the hands of a governor, who is chosen by the people for three years, but can hold the office only three years in six.

There is a college recently established at Newark; the State has also a school-fund, which produces an annual income of 9000 dollars.

This country was first settled by the Swedes, whom Gustavus Adolphus sent there in 1627. In 1655 it passed into the hands of the Dutch, who ceded it in 1664 to the English. Its name is derived from Lord Delaware, the governor of Virginia. (Darby; Warden, &c.)

DELEGATES, COURT OF, was the great court of appeal in ecclesiastical causes, and from the decisions of the Admiralty Court. It was so called because the judges were

delegated or appointed by the king's commission under the great seal; they usually consisted of judges of the courts at Westminster and doctors of the civil law, but lords spiritual and temporal might be joined. This court was established by the statute 25 Henry VIII., c. 19, which was passed in consequence of the practice which still prevailed of appealing to the pope at Rome from the decisions of the English courts in the above-mentioned matters.

By the constitutions made at Clarendon, 11 Henry II., this practice had been condemned; but though frequently checked, it was never thoroughly broken off until the final rupture with the court of Rome, in the reign of Henry VIII. Appeals lay to the court of delegates in three cases—1, where sentence was given in any ecclesiastical cause by the archbishop or his official; 2, where any sentence was given in an ecclesiastical cause in place exempt; 3, where sentence was given in the admiralty, in suits civil and marine, according to the course of the civil law. After sentence by the delegates, the king might grant a commission of review; but the power was rarely exercised, except upon the ground of error in fact or in law, and it was usual to refer the memorial praying for a commission of review to the chancellor, before whom the expediency of granting the prayer was argued.

By statute 2 and 3, William IV., c. 92, the Court of Delegates was abolished, and its powers and functions were transferred to the king in council [PRIVY COUNCIL]; and by the same statute, it is enacted that the decision of the king in council shall be final, and that no commission of review shall in future be granted. (Cowell's *Interpreter*; Bl. *Com.*)

DELFT, a large town in the province of South Holland, on the high road between Rotterdam, the Hague, and Leyden, and about nine miles from Rotterdam. The canal of Schie skirts the road for the greater part of the distance from Rotterdam to the Hague. Delft is an antient and gloomy town; many of the streets are divided by narrow stagnant canals, which are cleaned out by means of sluices: in the centre of the town are two handsome streets with broad canals and shaded with trees. The greater part of the country-houses inhabited by the wealthy merchants of Rotterdam are situated on the banks of the canal near to Delft; the population of the town amounts to 15,000.

Delft was formerly a place of some importance as the seat of the manufacture of a species of pottery, to which it gave its name. The improvements introduced into this manufacture by Wedgwood gave so much advantage to English potteries that those of Holland soon ceased to be of any importance, and in this respect Delft is no longer a place of note. The learned Grotius was born in this town, and his remains are deposited in the new church, a large building which contains one of the most splendid mausoleums in Europe, that of William the First, Prince of Orange, who was assassinated in his palace in Delft in 1584. The mausoleum consists of a sarcophagus, on which is a recumbent statue, in white marble, of the prince, with his faithful dog at his feet. At the four corners are bronze statues representing Liberty, Fortitude, Justice, and Religion. Under an arch at the head of the tomb is another statue, in bronze, of the prince in a sitting posture and in full armour; and at the opposite end is a figure representing Fame, with expanded wings. Over the whole is an exquisitely-wrought canopy supported by four buttresses of white marble, and twenty-two columns of black Italian marble. The town-house stands on one side of a large market-place, and opposite to the new church. It is a very antient building of two stories, with pointed windows, each of which has gilded ornaments beneath it; the walls are painted of a brownish yellow colour. The old church is in another part of the town, and is remarkable only for containing the tombs of Leuvenhoeck and Van Tromp.

At the establishment of the confederation of the United Provinces, Delft was an important town, being one of the six places which first sent deputies to the Assembly of the States. Manufactures of woollen cloths and tobacco-pipes are carried on, as well as a considerable trade in butter, the canal by which it is connected with Rotterdam giving to the town the advantage of a sea-port.

DELHI, a province of Hindustan, lying between 28° and 31° N. lat., bounded on the north by Lahore, on the east by Oude and northern Hindustan, on the south by Ajmeer and Agra, and on the west by Ajmeer and Lahore. It extends east to west from the hilly countries to the cen-

tral desert, a distance of 240 miles, and in breadth, from north to south, about 200 miles. The province is generally level. To the north of the city of Delhi is a ridge of low hills, that joins the mountains between the Sutledge and the Jumna. Except on the banks of the rivers by which it is traversed, the soil of the province is in a high degree arid and unproductive, but great pains have been taken to remedy this disadvantage by means of irrigation. The province is watered by the Ganges, the Jumna, the Caggur, the Chittung, and the Seraswati, which last was formerly of some magnitude, but is now an inconsiderable stream. In addition to these rivers several artificial canals of great extent have been made. The canal of Ali Merdan Khan extends between the city of Delhi and the upper part of the Jumna, which river it joins opposite to Kurnal, 100 miles higher up than the spot upon which the city of Delhi stands. This canal had long been choked up, but was cleared out and repaired by the English at an expense of 35,000*l.*: the work was undertaken in 1817, and finished in 1820. This canal supplies the inhabitants of Delhi with water for domestic purposes, that of the Jumna, below Kurnal, being much impregnated with earthy salts, owing to which circumstance the overflowing of this river is not followed by the same improvement of the soil which results from the deposits left by the waters of the Ganges and other rivers of Hindustan. Before the restoration of Ali Merdan Khan's canal, the country around the city of Delhi had become scarcely habitable through the deleterious effects of the water. The canal of Sultan Feroze Shah commences from Ali Merdan Khan's canal a little below Kurnal, and is carried to the westward through Hurriana to the frontiers of Bikaner. The object of this canal was the irrigation of the country through which it has been carried, and which was before dependent upon the periodical rains. This work, which was undertaken in the thirteenth century, had become useless from neglect, when, in 1823, its restoration was undertaken by the English. The Great Dooab canal joins the Jumna a few miles below the place where it issues from the northern mountains, and is carried to the same river nearly opposite to Delhi, a distance of 150 miles. The original constructor of this canal is not known: it is called Zabeta Khan's canal, because a Rohilla chief of that name attempted to restore it, but at that time it was an antient work. It passes through Saharunpore, Rampore, Shamlee, and some other towns, and gives fertility to an extensive tract of country. It is matter of tradition, that Sultan Feroze III. constructed various other canals, water-courses, and conduits, which having been neglected in after years, have been completely choked up, and every trace of them lost. Wheat, barley, gram, and other grains are produced in that portion of the province which lies between the Jumna and the Sutledge, but the long-continued droughts in the western part of Delhi are unfavourable to husbandry. During the rainy season, when the rivers overflow their banks, the pasturage is good, but there are large tracts of country which exhibit only a naked sterility, without cultivation and without trees. The Rohilla district, lying between the east bank of the Ganges and the kingdom of Oude, has a fertile soil and a genial climate. The country is there traversed by numerous streams, which rise in the hills of Kumaon, and whose waters are collected in reservoirs. This district produces sugar and wheat abundantly. The many wars which occurred in the last quarter of the eighteenth century caused the land to be in a great degree neglected, and it has been computed that not more than one-half of the surface of the province is at present under cultivation.

The principal subdivisions of the province are the districts of Bareilly, Hurriana, Moradabad, Shahjehanpore, Rampore, Merut, Saharunpore, Sirhind, and the principality of Pattiallah.

The city of Delhi was taken by Mahmood about the year 1011, and laid under contribution. This province was afterwards the seat of empire under the Guarian or Afghaun monarchs. The Mogul dynasty was founded by Baber in 1525, when the last of the Afghaun monarchs having been slain by him in battle, he ascended the vacant throne, less as a conqueror than as the deliverer of the people, his army having been principally composed of deserters from Ibrahim the Afghaun sovereign. The throne continued in the possession of this monarch and his descendants until the establishment of the English in India. In the reign of Mahomed Shah III., who died in 1749, the kingdom was invaded by Nadir Shah, and the royal trea-

sury was plundered of vast sums in money and jewels; the vice-roys of the different provinces revolted, and gained their independence one after the other, so that the successors of Mahomed Shah possessed only the actual sovereignty of the city of Delhi and a small district around it. Between 1749 and 1760 three monarchs were successively dethroned: in the latter year Shah Allum II. commenced his reign by an attack upon the English in Bengal, but, being defeated, surrendered himself unconditionally. Upon this, Meer Caussim, a creature of the English, was invested by the Mogul with the government, as Soubahdar of Bengal, Bahar, and Orissa, and engaged to pay out of the revenues of those provinces twenty-four lacs of rupees (240,000*l.*) annually to the mogul. This payment was allowed to fall into arrear, and in 1765 the Mogul was induced by his necessities, and in order to secure payment of the annuity in future, to issue a phirmaun granting to the East India Company what is known in history as the Dewannee, empowering them to collect and appropriate the revenues of Bengal, Bahar, and Orissa. In the following year, under a little gentle compulsion, the Mogul was induced, 'by way of inauum, or free gift,' to assign to the English the Northern Circars. From this time the Mogul retained only a nominal sovereignty; he was attacked first by the Maharattas, and next by the Rohillas, who became masters of the imperial city in 1788, and put out his eyes. After this Shah Allum transferred the small remains of his territory to some French officers in the service of the Maha Rajah, and became a prisoner in the hands of the Maharattas. This state of things continued until 1803, when Lord Lake, after defeating Dowlut Rao Scindiah, took possession of the city and territory of Delhi, and assigned lands for the support of the Mogul, thenceforth entitled King of Delhi. These lands are managed by British officers, and out of the revenue which they yield provision is made for the support of the numerous members of the royal family. These payments, including the sum appropriated for the expenses of the king, amount to upwards of thirteen lacs of rupees (130,000*l.*) a year.

The consequences of the immediate administration of the government by the British have been highly favourable to the inhabitants. Owing to the weakness of the former rulers, many of the villages had found it necessary to unite for their mutual protection, and by this means the more powerful were able to set the government at defiance as regarded the payment of taxes, while the burthen fell the more heavily upon the small and less powerful villages. When the English first took possession of the territory there were about 600 villages that had been deserted, the greater part of which were speedily re-peopled, and chiefly by the old inhabitants or their descendants. The restoration of some of the antient canals, as already mentioned, has been of signal benefit to the people. When, in consequence of the clearing out of Ali Merdan Khan's canal, the water was known to be approaching the city of Delhi, the people went out in swarms to hail it, calling down blessings upon those by whose exertions they were thus benefited. The appearance of the inhabitants indicates that their circumstances are easy; the whole population is well clad, which, in a climate where clothing is not of prime necessity as a protection from the elements, is alone evidence of prosperity. The tenure of the land has never been interfered with by the English, as in other provinces of India. Settlements are made with the village proprietors according to immemorial usage, and no sales of land have been rendered necessary by the possessors falling into arrears. The holders of land are divided into five classes, viz. 1. biswadars, or freeholders, generally descendants of the original settlers of villages; 2. hereditary occupants not liable to ejection, answering to copyholders in England—this class pays certain fixed dues to the biswadar; 3. tenants at will residing in the villages; 4. tenants at will not residing in any village; 5. mortgagees. The rates paid by each of the other classes to the biswadar have not been ascertained, but it is understood that they are not liable to fluctuation. The land-revenue of the province collected by the Company's government in 1829-30 amounted to 70,54,948 rupees (705,495*l.*).

DELHI, the capital of the province, is situated on the west bank of the Jumna, in 28° 41' N. lat., and 77° 5' E. long. According to tradition this city was founded 300 years before the Christian æra by Delu. It formerly stood on the left or eastern bank of the Jumna, and is said to

have covered a space of twenty square miles. Bernier, whose account was written in 1663, four years after the accession of Aurengzebe, estimated the circumference at no more than three leagues; but this included only the part within the fortifications, and there were several suburbs, which probably were not very thickly covered with buildings. It is known that this capital was greatly extended in the course of the reign of Aurengzebe, and Major Rennell mentions two millions as the number of inhabitants which it was said to contain at the end of the seventeenth century. The extent of the ruins seems to justify in a great degree this estimate. The Emperor Shah Jehan built a new city in 1631 on the right bank of the Jumna, and gave to it the name of Shahjehanabad, which it has not retained. This is the modern Delhi, which is about seven miles in circumference, and surrounded by walls constructed of large blocks of grey granite: several towers and bastions occur in the walls at intervals. The city has seven gates of freestone, and contains the remains of several fine palaces, the former dwellings of the chief omrahs of the empire. These palaces are each of considerable extent, and surrounded by high walls, containing baths, stabling, and numerous out-buildings. There are several beautiful mosques in good preservation; the largest of these, the Jumma Musjeed, was built by Shah Jehan, and completed in six years. It is built of white marble and red sandstone. There are two fine streets, one 90 feet broad and 1500 yards long, the other 120 feet wide and a mile in length. Down the middle of the first of these streets is an aqueduct, supplied with water from Ali Merdan Khan's canal. The other streets are narrow, but contain many good brick houses. The Mogul's palace, built by Shah Jehan, on the west bank of the Jumna, is surrounded on three sides by a wall thirty feet high, and more than a mile in circumference. It is now used as a bazaar. The chief hall of audience is an open quadrangular terrace of white marble, richly ornamented with mosaic work and sculptures in relievo; and the chapel of Aurengzebe, also of white marble, although small, is of beautiful workmanship: altogether the building, even in its present neglected state, attests the magnificence of its former occupants. The gardens, which were formed by Shah Jehan, are said to have cost a crore of rupees—one million sterling. Their original character has long been completely lost, and they now present the appearance of a small neat park, with some charming groves of orange-trees. Among the ruins of the antient city on the eastern side of the river are some splendid mausoleums in good preservation: those of the Emperors Humaïoun and Mahomed Shah, and of Jehanara Begum, daughter of Shah Jehan, are the most remarkable. One of the most generally useful works of the Emperor Shah Jehan in this city is the well, excavated by great labour out of the solid rock upon which the Jumma Musjeed is built. The water is raised from a great depth by complicated machinery to a succession of reservoirs, and fills a pond, from which the inhabitants obtain a supply. The principal wheels having been broken, and the whole machinery out of repair, it was restored by the English a few years after they obtained possession of the city.

This city has at various times undergone great vicissitudes, having frequently been taken by hostile powers, and once, as already mentioned, wholly depopulated through the whim of the Sultan Mahomed, who removed the whole of the inhabitants forcibly to Dowlatabad, near the middle of the fourteenth century. At the close of the same century Delhi was captured and plundered by Timur, during the reign of Nassir Ed Din, whence it would appear that its population had returned. In 1739 the city was again taken and plundered, and part of the suburbs burned, by Nadir Shah. Between that period and the occupation by the British, Delhi was taken by the Abdallees, by the Vizir Gazee Ed Din, and twice by the Maharattas.

No census of the inhabitants has been taken, but it is estimated that the city contains a population of 200,000. This place is well situated for carrying forward the trade between the peninsula of India and the countries to the north and west; the inhabitants consequently exhibit a considerable degree of industry and commercial activity. Cotton-cloths and shawls, for which last the wool is brought from Cashmere, are manufactured in the city, and much indigo is produced in the surrounding country. A considerable trade is also carried on in precious stones, and in large black and red carnelians.

From time to time many endowments had been made by benevolent natives for providing instruction for poor children; these endowments had nearly all been diverted from their intended object, and nothing could be more unsatisfactory than the state of education among the poorer, and indeed among all except the most wealthy, inhabitants of Delhi, at the time of the appointment by the English government in India of a General Committee of Public Instruction, which was planned and brought into operation between 1823 and 1825. A college or madrisa was established by this committee, and funds were assigned for its support by the central government, in addition to which a sum equal to 17,000*l.* was presented to the college by Nawab Islamaid-ood-Dowlah, late minister of the king of Oude. In addition to this establishment, it appears that in June, 1827, there had been opened 247 schools in Delhi and its immediate vicinity for the instruction of poor children. The number of pupils at the college, which in 1829 was 152, had increased in the following year to 257. More recently another school has been instituted, at which the children of the native gentry are taught the English language, and as many as 68 scholars attended in the first year of its establishment.

Delhi is distant from Calcutta, by the Birbhoom road, 956 miles; from Bombay, by Ahmedabad and Ajmeer, 880 miles; from Madras, by Ellichpore, 1275 miles; from Agra, 117 miles; from Benares, 496 miles; from Lahore, 386 miles; from Oude, 364 miles; and from Seringapatam, 1321 miles; all travelling distances.

(Rennell's *Memoir of a Map of Hindustan*; Mill's *History of British India*; *Reports of Committees of Lords and Commons on the Affairs of India*, 1830, 1831, and 1832.)

DELIAN PROBLEM. [DUPLICATION.]

DELILLE, JACQUES, was born at Auvergne in the year 1738, and educated at Paris at the College de Lisieux. Poverty compelled him to accept the office of subordinate teacher at the Collège de Beauvais; but he was soon raised to the rank of professor of humanity in the college of Amiens. While holding this office he commenced a translation of Virgil's *Georgics*. On his return to Paris he was appointed professor at the Collège de la Marche. He now began to be known as a poet, and several of his pieces attained celebrity, particularly an epistle to M. Laurent. But it was the publication of his *Georgics* that raised him to distinction, a work to which he was urged by Racine. The public read this translation with enthusiasm, and thought that the French language was capable of representing all the beauties of antiquity. Envy, notwithstanding, appeared here and there; and old forgotten poets were dragged from oblivion, that their works might be lauded at the expense of M. Delille's reputation. In 1774 the author was elected a member of the Académie, and soon after published his celebrated poem 'Les Jardins.' The popularity of this work does not seem to have been equal to that of the *Georgics*.

Delille accompanied M. de Choiseul Gouffier on his embassy to Constantinople, and took the opportunity of visiting Athens. It was on this tour that he composed his poem 'L'Imagination.' On his return to Paris he became professor of Belles-lettres at the university, and of Latin poetry at the Collège de France. He was unfortunate enough to lose all his property by the Revolution. At the celebration of the Fête de l'Être Suprême, which took place during the Reign of Terror, Robespierre demanded of Delille an ode for the occasion. The poet, finding refusal was of no use, astonished Robespierre by writing a dithyrambic poem on the immortality of the soul, wherein he warmly supported that doctrine. The troubles of the capital induced him, in 1794, to leave Paris for St. Diez, and subsequently to retire to Switzerland, where the government of Berne made him a citizen. Here he finished his 'Homme des Champs' and 'Les Trois Règnes de la Nature.' He afterwards visited London, where he translated Milton's 'Paradise Lost.' In 1801 he returned to Paris, and died, universally regretted, in 1813.

Delille is one of those poets who will always be honoured by posterity; he reformed the language, and wrote verse with an ease and elegance before unknown. Those who feel pleasure in hearing the Alexandrine verse must be pleased (as far as structure goes) with the didactic poems of Delille. Nothing can be conceived more smooth and easy than the flowing of his lines; and even when he writes in a measure more irregular, as in 'La Conversa-

tion,' the same correctness is so carefully attended to, that a person of the slightest ear may read him aloud without once hesitating as to the place where the cæsura lies. To say he was a poet of great imagination would be going too far; but he is entitled to higher praise than that of a mere verse-maker. His images, as well as his lines, are often exceedingly elegant: we may instance an expression in 'Les Jardins,' where, after observing that the beauty of his subject ought to inspire him, he says—

— 'Comme un rayon pur colore un beau image,
Des couleurs du sujet je teindrai mon langage.'

His 'Conversation' is an amusing poem; it is a kind of Theophrastus in verse, portraying the different sorts of persons who figure in conversation. It has, however, the fault of most works that treat of characteristics—the persons who appear in it are personified abstractions, instead of individuals as they appear in nature.

DELIQUESCENCE, the change of form which certain bodies undergo from solid to fluid by exposure to the air, and absorbing moisture from it.

There are many substances which partake of this property: among the more remarkable are potash, carbonate of potash, chloride of calcium, and nitrate of copper; all these will in a short time attract sufficient water from the air to become fluid in it. Other saline bodies are deliquescent only in moist air, such as common salt and nitrate of ammonia.

Certain deliquescent salts, and more especially chloride of calcium, are employed for the purpose of drying gaseous bodies which are the subject of experiment.

DELISLE, WILLIAM, a French geographer of great celebrity in his own day, was born at Paris, in 1675. His inclination for the pursuit in which he afterwards became so eminent, was displayed at an early age, and he made considerable proficiency in the art of constructing maps before he was nine years old. This taste was induced and carefully cultivated by his father, who appears to have been also much devoted to geographical and astronomical pursuits.

In 1699 he published a map of the world, which, with other maps and dissertations on geography, led to his election as a member of the Academy of Sciences in 1702; and a little afterwards he was appointed geographer to the king, with a pension. Indeed several of his works were written for the use of his royal pupil, in the course of instruction which he condescended to receive from Delisle.

Delisle's celebrity was not only so great in his own country that no work of history or travel was considered complete without his maps, but it extended all over Europe. He had several flattering invitations from the monarchs of other countries to remove to their capitals; and Peter the Great paid him a personal visit at Paris, to attempt to induce him to go to Russia. All these offers he rejected, but he gave Peter an excellent series of maps of his immense dominions. Fontenelle, in his 'Eloge,' says that the geographer knew their limits better than their owner did himself; and it was probably the respect entertained for him by the Czar that led to his brother Joseph being appointed to take charge of the observatory at Petersburg, with a very considerable salary.

In 1726, Delisle died of apoplexy, aged 51. The most valuable of his writings may be seen in the *Memoirs of the French Academy*; but any list of them is unnecessary here.

DELISLE, JOSEPH NICOLAS, a younger brother of the preceding geographer, was trained in the same school, and became very eminent in the same pursuits. He was born in 1688.

His published labours commenced with an excellent observation of the great total eclipse of the sun in 1706, when he was only 18 years of age; and in 1714 he was admitted a member of the Academy, in the section of astronomy. In 1724 he visited England, and at the recommendation of Newton and Halley, by both of whom he was greatly esteemed, he was elected a Fellow of the Royal Society, on the foreign list. In 1726, the year in which his brother died, he was appointed astronomer to the Czar Peter, a situation which he retained 21 years, when he returned to Paris on account of his health. He was then appointed professor of astronomy in the Royal College of France, which he held many years. Amongst his pupils were Lalande and Messier.

He died in 1768, at the age of 80; having published, besides his 'History of Astronomy' (2 vols. 4to, 1738), no

less than 44 papers in the 'Memoirs of the Academy,' and several other dissertations elsewhere.

DELOS (Δῆλος), a small island of the Archipelago, one of the group called Cyclades, lies in the strait between Mycone and Rhenea. According to the poetic tradition, it was originally a floating island. (Strabo, p. 485.) It had several antient names, as Ortygia, Cynthia, and Asteria. It was celebrated from the earliest times as a seat of the worship of Apollo, who was said to have been born there. His temple and that of his mother, Latona, were in the town, which was built on a little plain on the west side of the island, at the foot of a lofty mountain, called Cynthus. (Strabo, p. 485.) The river Inopus ran into the sea to the south of the town; and in the sacred inclosure was a diminutive circular lake, called the τροχοειδὲς λίμνη. (Herod. ii., 170; Tournefort, Voyage du Levant, tom. i., p. 290, fol.) Delos was a place of meeting for the Ionians in the time of Homer; and athletic sports, with dancing and singing, were carried on there in honour of Apollo. (Thucyd. iii., 104.) Polycrates, of Samos, consecrated the adjoining island, Rhenea, to the Delian God, and joined it to Delos by a chain. Delos fell into the power of the Athenians in the time of Peisistratus, and then a partial purification of the island took place by the removal of the tombs which were within sight of the temple. In the year 426 B. C. a complete purification of Delos was made by the Athenians; all the tombs there were removed, and it was proclaimed that no one should thenceforth die or be born in the island, but that all persons likely to die or bring forth should be sent over to Rhenea. (Thucyd. i. 8, iii. 104.) The Athenians instituted at Delos a festival, which returned at the beginning of every fifth year, called the Delia, and sent thither annually a sacred vessel, called the Theoris, in commemoration of the delivery of Athens by Theseus from the Cretan tribute. (Plat. *Phædo*, p. 58, A.) The Persians regarded Delos with so much veneration, that when they were sailing to Eubœa, in 490 B. C., they would not land there, but sent to offer a most sumptuous sacrifice to the Delian Apollo. (Herod. vi., 97.) It was probably on account of the respect which all parties paid to this temple that the Athenians selected it as the depository of the tribute which they collected from their allies after the Persian war. (Thucyd. i., 96.) In 422 B. C. the Athenians removed the whole population of Delos to Adramyttium, where they were allowed to settle by the satrap Pharnaces (Thucyd. v., 1), and where many of them were afterwards treacherously massacred by the Persians. (Thucyd. viii., 108.) When Corinth was destroyed by Mummius, Delos succeeded to the commerce of that city, and was for a time very flourishing; but the generals of Mithridates having landed there in the war between that monarch and the Romans, the island was laid waste by them, and remained in a state of great desolation. (Strabo, p. 486.) In the days of their prosperity the Delians carried on a very extensive slave-trade with Cilicia, and thousands of slaves were landed and sold in a single day. (Strabo, p. 668.) The modern names of this little island are Delo, Deli, Dili, and Sdilli. It is little more than a mass of bare rock.

DELPHI, now called CASTRI, the name of a people and a town of Phocis, celebrated for the oracle of Apollo. Its original name was Pytho; and Homer does not call it by its more modern appellation, which seems to have been derived from the cavern whence the prophetic vapour issued, or from the serpent which Apollo slew there. (Hesych., Δελφός-μήτρα, καὶ ὁ ἐν Δελφοῖς ὄρακόν.) From the description which Strabo gives of the cavern (p. 419, ἀντρον κοῖλον κατὰ βάθος οὐ μαλὰ εὐρύστομον), and from the fact that Delphi was called the navel of the earth, it should seem that the former derivation is preferable. There was a legend that two eagles, sent by Jupiter from the east and west, met at Delphi; and in the temple was a stone adorned with two golden eagles, and other devices, which was called the navel-stone: representations of this may be seen on many antient monuments; as, for instance, in the

bas-relief representing the combat between Apollo and Hercules for the Delphic tripod. (Bekker's *Augusteum*, t. i., pl. 5.) The oracles were delivered by a priestess, who sat upon a tripod placed over the mouth of the cavern, and who, having exhaled the vapour, pronounced some prophecy in verse or prose: if in prose, it was afterwards set to verse by the poets attached to the temple. The oracle is said to have been suggested by the effects produced by the vapour upon some goats and the man who attended them. (Pausan. *Phoc.* 5.) The great reputation of the Delphian oracle made it the richest shrine in Greece, as every person who was satisfied with the response he obtained made a point of offering some costly donation to the temple. The first stone temple at Delphi was built by Trophonius and Agamemes: this having been destroyed by fire B. C. 548, a new one was built by the Amphictyons from the proceeds of a voluntary subscription, to which even Amasis, the king of Egypt, largely contributed. The Alcmaeonidæ, who contracted to build it, very liberally substituted Parian marble in the front of the building for the common stone of which they had undertaken to construct the edifice. (Herod. ii., 180, v. 62.) The wealth of Delphi naturally attracted plunderers. The Persians under Xerxes made an unsuccessful attempt to get possession of the treasures accumulated there. (Herod. viii., 37.) The Phocian leaders in the sacred war did not hesitate to appropriate them as a fund for the payment of their mercenaries (Strabo, p. 421); and Brennus, the Gallic king, subsequently carried off the greater part of the offerings which remained. (Strabo, p. 188.) [BRENNUS.] There were however still some objects for the rapacity of Nero, who carried off 500 bronze statues at once. (Pausan. *Phoc.* 5.) The city of Delphi, which was the largest in Phocis (Pausan. *Phoc.* 34), was situated on an elevation, sixteen stadia in circumference, at the foot of the south side of Parnassus (Strabo, p. 418); and as the focus of the Dorian religion, and the seat of the most celebrated oracle in Greece, it naturally became populous and wealthy. The population consisted of Dorians, who formed the privileged class, and of the descendants of the bondsmen of the temple. The constitution was originally monarchical (Müller, *Dor.* iii., 6, § 10); the kings were also called Prytanes. (Müller, iii., 8, § 3.) The Dorian families made an oligarchy, from which the priests, the Pythian court of justice, and a limited senate, were chosen. (Müller, iii., 9, § 17.) Delphi was, from very early times, the rendezvous of an important federal union, or amphictyony, the organization of which is attributed by Strabo, p. 420, to Acrisius. (Thirlwall, *Hist. Greece*, vol. i., p. 376.)

[Coin of Delphi.]

British Museum. Actual Size. Silver. Weight, 22½ grains.

DELPHIA, a vegetable alkali, which exists combined with malic acid, forming malate of delphia in the seeds of the *delphinium staphisagria*, or stavesacre.

The properties of delphia are that it is a crystalline powder, which becomes opaque by drying. It is nearly insoluble in water, but communicates its peculiar taste to it. It dissolves readily in alcohol and æther, and, on the cooling of the solutions, the delphia is deposited in flocks. It is soluble also in the volatile and fixed oils.

With acids it forms neutral salts, which are crystallizable, and have a bitter and acrid taste; they are however but little known, and delphia itself has not been analysed. Like the other alkalis of this class, there can however be no doubt of its being composed of hydrogen, carbon, oxygen, and azote.

DELPHINA'PIERUS. [WHALES.]

DELPHI'NIUM, an extensive genus of the Ranunculaceæ order, consisting of annual or perennial herbaceous plants, with irregular spurred flowers, the colours of which are often of the most vivid blue. They are very nearly allied to Aconites, from which they differ merely in their upper sepal being lengthened at the base into a spur instead of at the back into a helmet, and in the petals having no spur at all, but being deformed stalked bodies altogether different in form, and often in colour, from the sepals.

The species abound in the temperate parts of the northern hemisphere, and are often cultivated in gardens under the name of Larkspurs. Among the most showy kinds are

Delphinium Consolida, a hardy annual, of which many varieties are known as Rocket Larkspurs, *D. Barlowii*, a magnificent double-flowered perennial hybrid, and the Bee Larkspurs, consisting of *D. grandiflorum*, *Sibiricum*, *Chinense*, *mesoleucum*, and many more. These latter derive their name from a striking resemblance on the part of the petals to the black body of a humble bee covered with yellow hairs; the head and legs of the insect being supposed to be immersed in the cup of the flower.

The only species that has been applied to any useful purpose is stavesacre, *D. Staphisagria*, an annual inhabiting the warmer countries of the South of Europe. It has an upright branched stem, about two feet high, covered all over with close velvety down, and generally of a greenish purple colour. Its lower leaves are round, on long stalks, heart-shaped at the base, and divided into five, seven, or nine deep lobes of an oval or lanceolate figure; they are sharp-pointed, and either undivided or cut into a few lateral incisions; on the upper side they are deep green and almost smooth; on the under, they are paler and velvety. The flowers are a dull greyish green, arranged in a lax spike at the extremity of the ramifications of the stem; their stalk is short and velvety, and has three linear short bracts. The sepals are green and velvety externally, with a short spur curved downwards. The four petals are separate from each other and smooth; the two upper are oval, and rather long; the two lower have short stalks, and a rounded, irregular, toothletted limb. The fruit is composed of three woolly capsules filled with greyish irregularly-triangular compressed very acrid bitter seeds.

DELPHINIUM STAPHISAGRIA, a biennial plant. Stavesacre seeds are not now used internally: when introduced into the stomach they cause vomiting, purging, and local ulceration of the intestines, and they may even produce serious general effects. When powdered, they are employed externally for the destruction of lice, or they are dissolved in vinegar and made into an ointment, which is employed for the cure of scabies, which it is said to effect in seven or eight days, and which has found favour in the eyes of some persons, as it does not stain the linen, nor has the unpleasant smell of sulphur. Its external application to abraded surfaces is not free from danger. The only case in which its employment is justifiable is, not to remove, but cause revulsion of, the cutaneous eruption, when, by its sudden drying up, the internal organs are oppressed, as, like most ranunculaceous plants, it causes acute inflammation and pustulation of the skin. It contains an alkaloid, *delphia*, which is soluble in alcohol and æther, and which forms salts with acids.

DELPHINORHYNCHUS. [WHALES.]

DELPHINUS. [WHALES.]

DELPHINUS (the Dolphin), one of the old Greek constellations, referred to the fable of Amphitrite and to that of Arion. It succeeds *Aquila* in the heavens, and its principal cluster comes on the meridian about three quarters of an hour later than the principal star (α) of the latter, and nearly in the same declination.

DELTA, the name of the fourth letter of the Greek alphabet. It was originally given by the Greeks to that part of Lower Egypt which, being comprised between the two main branches of the Nile and the sea, had a triangular form, somewhat resembling the Greek letter Δ . The same name has since been extended to all those alluvial tracts at the mouths of great rivers which, like the Nile, empty themselves into the sea by two or more diverging branches, though the spaces circumscribed by these branches and the sea-line have, in many cases, very little of the triangular form.

Of the different circumstances which contribute to the formation of deltas two are essential: first, the river, in the lower part of its course, must open out or spread sufficiently to have the motion of its waters considerably retarded; and secondly, it must either be habitually or periodically charged with fine detrital matter, which it deposits when its motion is diminished or its progress checked.

The operative process of formation varies in different cases: we shall confine ourselves to the more general.

Whenever, in consequence of heavy rains in tropical countries, or sudden thaws in more northern climes, rivers become greatly and rapidly swelled, their channels can no longer contain them, and they therefore overflow the lowlands at their embouchures to a greater or less extent. The waters thus spread out have their velocity diminished, and hence let fall the fine detrital matter with which they are charged. This detritus, though it covers the whole of the inundated surface, does not form in all parts a stratum of equal thickness. Every deviation from horizontality in the inundated land produces a particular and corresponding current in the moving mass of waters. Every tree, hillock, stone, or other obstruction, causes an eddy, and the natural result of these various currents and eddies is to distribute the sediment unequally over the bottom. When the waters begin to subside, some portions of the land are uncovered before the rest, forming, as it were, a number of islands. The water continuing to run off between these, deepens the hollows still more, so that when the inundation has all run off, the whole space is more uneven than it was before, and intersected by numerous incipient channels. The floods of the succeeding years increase the effect, until, in course of time, the highest parts are so raised, and the intervening channels so deeply excavated, that the latter constitute permanent branches of the river, and a delta is formed.

An inundation however is not always necessary to the formation of a delta. If the mouth of a river be large, a delta may be formed by another process. Thus, when the river is charged with mud or sand, it is found that the middle of the stream is the most loaded, because its rapidity is there greatest; hence, when that rapidity is diminished, as it is of necessity on reaching the wide mouth, or æstuary, a central deposit is formed, which in time rises above the surface and becomes an island, dividing the stream into two branches. Every succeeding flood brings a fresh tribute to the island, which increases seaward; for while the upper end is abraded by the impinging of the main stream, there is a dead water immediately in front of the lower part where fresh detritus continually subsides. Nor does the island increase merely in length: it also acquires breadth, the two branches of the streams diverging more as they advance. Hence the alluvial island acquires something of a triangular form. If the river be large, the lateral branches will be disposed each to form a minor delta upon the same principle as the main stream did. Thus new branches are formed, some of which converge towards the prolongation of the line of the main trunk. The sinuosities of the deltoid branches also drive their currents, in some places, back upon the island, in which, from its loose texture being favourable to abrasion, indentations are easily made, and finally channels cut through, dividing it into two or more. From these operations, simply or combined, the alluvial tract is frequently intersected by a great many deltoidal branches, dividing the whole into what, for the sake of distinction, may be termed *deltoid islands*. Such deltas, however, can hardly be formed upon coasts subject to tides; they almost exclusively occur at the mouths of rivers dis-emboguing into lakes or tideless seas. The numerous banks at the mouth of the Thames would soon rise into islands, and a delta would be formed, were it not for the effect of the tides.

In some cases, deltas owe their formation almost wholly to the nature and direction of the currents of the ocean, the

form and nature of its bed in the neighbourhood of the mouths of rivers, the prevalent winds and tides, &c. In almost all cases these circumstances greatly modify their form and extent and nature. Some deltas are very extensive; some are sterile, while others are highly fertile, such as the delta of the Nile; some are thickly wooded, such as the delta of the Ganges; some are swampy, as the delta of the Mississippi, &c. With regard to the branches which inclose or intersect them, there is also much variety, both as to their total number, and the number and situation of such among them as are navigable. Sometimes the two outer or deltoid branches of the river are the largest; sometimes one only is navigable, and that may be in the middle or on either side, and sometimes many are navigable; thus the delta of the Wolga has sixty-five channels, eight of which are navigable; the Orinoco fifty, of which seven are navigable. The Danube has five navigable mouths, and the Nile at present only two.

Deltas are formed not only at the mouths of rivers which disembogue into the sea, but sometimes at the confluence of tributary streams, with their recipients, as is seen in many rivers of America; such as the Rio Branco and the Rio Jupura, which respectively enter by a great number of branches into the Rio Negro and the Marañon, or river of Amazons. Rivers entering lakes also, as we have already hinted, form deltas at their mouths.

Some deltas are still in progress of formation; others have been obliterated by various causes, and all are, more or less, undergoing different modifications.

The principal deltas of Europe are those of the Rhone, the Danube, and the Po. Many other rivers, however, form deltas, such as the Ebro, the Vistula, the Neva, the Dwina, the Don, &c. The delta of the Rhine has been, as it were, obliterated by the irruption of the Zuydersee, though the whole of Holland is a formation of deltoid islands, created by the anastomosing branches of the Rhine, the Meuse, and the Scheldt. The deltoid form of the mouths of the Petchora is no longer recognizable in the group of islands at its embouchure.

In Asia, the principal deltas are those of the Ganges, the Indus, the Irrawaddy, the Cavery, the Euphrates, the Oural, the Lena, and the Kolima.

The Wolga, before entering the Caspian, is split, as we have said, into innumerable branches; but the space which they inclose, in strictness, bears little resemblance to a delta.

In Africa, the Nile and the Niger; and

In America, the Mississippi and the Orinoco form the principal deltas.

DELU'C, JEAN ANDRE', was born at Geneva, 1727. His father, François Deluc, was a watch manufacturer, not only skilful in his trade but conversant with other branches of knowledge, and a writer upon religious and political matters. His son also took part in the disputes between the négatifs and the représentans, or aristocratic and democratic parties, of his native republic, to the latter of which he belonged, and he was sent, in 1768, by his fellow representatives to Paris to plead their cause with the Duke of Choiseul, the prime minister in France. On his return in 1770 he was made a member of the legislative council, but not long afterwards he left Geneva and its politics for England, to devote himself entirely to scientific pursuits. He had, from an early age, applied to the study of geology, and had made excursions in the Alps, while his brother investigated the mountains of Italy for the same object. His own words best explain his purpose: 'My brother and I entered together upon our geological career, while I yet lived at Geneva, and after a certain period we came to a first conclusion, which from that time has been our guide, namely, that an essential distinction was to be made among the various phenomena which the surface of the earth exhibits, with respect to their causes, by determining as to each of them whether the causes which have produced it are still in action, or have, at some epoch, ceased to act. . . . Continuing our observations, we came at length to a conviction that the formation of our continents, with regard both to their composition and general form, as well as their existence above the level of the sea, should be ascribed to causes no longer in action on our globe, and that the whole of the effects of the still-existing causes have been limited to a modification of that original state. After having quitted Geneva, I continued my observations in various countries, and more particularly on the sea coast; my brother like-

wise pursued his, and we communicated our remarks to each other. I saw the possibility of determining, by the action of actual causes, what had been the state of our continents at their birth, and also the possibility of determining the time elapsed since that period. I then wrote my first geological work, "Lettres Physiques et Morales sur l'Histoire de la Terre et de l'Homme," 8vo. La Haye, 1778.' These letters were addressed to Queen Charlotte, consort of George III., who appointed Deluc her reader; they relate only to the Alps of Switzerland; but in the following year appeared a continuation of the work, under the same title, including Deluc's travels through Rhenish Germany, Hanover, Friesland, Holland, Belgium, &c., in 5 thick vols. 8vo. These letters are not merely scientific treatises; they are also descriptive of scenery, of the inhabitants, and their manners; they contain statistical and moral observations, and many of them are full of interest even to the general reader. One great conclusion which Deluc came to from all his observations was, that the present continents were left dry by a great and sudden revolution of comparatively recent occurrence, not more than four or five thousand years since, which revolution buried under the sea the countries previously inhabited. This opinion has been also maintained by Saussure, Dolomieu, and Cuvier. Deluc agreed with Saussure in considering that the materials which form our mountains were first deposited in horizontal and continuous strata, and that their present broken and dislocated state is the effect of subsequent catastrophes, which however were previous to that which left them dry. Deluc's whole system concerning the various epochs of the creation corresponding to the six days or rather periods of Genesis, appears in several of his numerous works, and especially in his 'Lettres Géologiques sur l'Histoire de la Terre, addressed to Blumenbach, 1798; in his 'Traité élémentaire de Géologie,' 1808, which was also published in English; and in his 'Geological Travels in the North of Europe and in England,' 3 vols. 8vo., London, 1810. Deluc made also many observations on the atmosphere, and the phenomena of air, heat, and light. He wrote 'Recherches sur les Modifications de l'Atmosphère, contenant l'Histoire critique du Baromètre et du Thermomètre, un traité sur la construction de ces instrumens, des expériences relatives à leurs usages, et principalement à la mesure des hauteurs, et à la correction des réfractions moyennes; avec figures,' 2 vol. 4to., Geneva, 1772. It is perhaps in this branch of experimental philosophy that Deluc rendered the most positive services to science. He made great improvements in the barometer, especially as applied to the measurement of heights. [BAROMETER.] He also wrote 'Mémoire sur un Hygromètre comparable présenté à la Société Royale de Londres.' Among his other works may be mentioned, 'Idées sur la Météorologie,' 1786; 'Introduction à la Physique Terrestre par les Fluides expansibles,' 1803; 'Traité Élémentaire sur le Fluide Electro-Galvanique,' 1804.

Deluc's earnestness in availing himself of his geological observations to prove the veracity of the Mosaic narrative involved him in controversial correspondence with several of his contemporaries, and particularly with Dr. Teller of Berlin: 'Lettres sur le Christianisme, adressées au Dr. Teller,' 1801; 'Correspondance particulière entre le Docteur Teller et J. A. Deluc,' in French and German, 1803-4; and also with Professor Reimarus of Hamburg, 'Annonce d'un Ouvrage de M. J. A. Reimarus sur la Formation du Globe, par J. A. Deluc,' Hanover, 1803. But though Deluc was earnest in his religious conviction, and in supporting it by arguments, his spirit was far from being intolerant, as he shows in numerous passages of his works, and especially in his 'Discours sur la Tolérance,' in the 1st vol. of the 'Histoire de la Terre et de l'Homme.' He was a great admirer of Bacon, and wrote 'Précis de la Philosophie de Bacon, et des Progrès qu'ont fait les Sciences Naturelles par ses Preceptes et son Exemple,' 2 vol. 8vo., Paris, 1802. He wrote also on education: 'Lettres sur l'Education Religieuse de l'Enfance, précédées et suivies de détails historiques,' 8vo., 1799; besides many other memoirs, treatises, &c., which appeared in the *Journal des Sçavans*, *Transactions Philosophiques*, and other scientific journals, French, English, and German. He was a member of the Royal Societies of London, Dublin, and Göttingen, and correspondent of the academies of Paris, Montpellier, &c. He was appointed in 1798 Professor of philosophy and geology in the University of Göttingen. He passed several years in Germany, at Berlin, Hanover, Brunswick, &c. After the battle of Jena he re-

turned to England, where he passed the remainder of his life, chiefly at Windsor, where his situation of reader to the queen gave him a free access to the royal family, by the members of which he was much respected. He died at Windsor, November, 1817, in his 91st year. His brother and fellow observer Guillaume Antoine Deluc died at Geneva in 1812, and left a rich collection of mineralogy, which has been increased by his son André Deluc, who is the author of an 'Histoire du Passage des Alpes par Annibal,' Geneva, 1818.

DELVI'NO, a livas, or inferior pashalik, of European Turkey, occupying the greater part of the coast of antient Epirus, and especially of the districts of Chaonia and Thesprotia, from the Khimára mountains on the north-west to the river Acheron on the south-east, a length of about 70 miles. It extends inland between 20 and 25 miles. A ridge of mountains divides it to the north-east from the valley of the Voiussa, the antient Aous, in the pashalik of Avlona, and several other groups, among which are the mountains of Paramithia and of Souli, divide it to the south and south-east from the pashalik of Joannina. The river Kalamas, descending from the high lands near Joannina, flows through the country of Delvino, and enters the Adriatic north of the bay of Gomenizza. A great part of the coast of Delvino faces the island of Corfu. Delvino, the head town of the pashalik, said to have about 8,000 inhabitants, is situated inland, about 15 miles north-east of Butrinto, the antient Buthrotum. Farther north, among the mountains, is Gardiki, the population of which was exterminated by Ali Pasha. Parga, formerly a Venetian possession, lies on the south coast of the pashalik of Delvino. Philates, near the banks of the Kalamas, is inhabited by a tribe of warlike Epirotes. There are no other places of any importance in the pashalik.

DELVI'NO, a town in the interior of Albania (Turkey in Europe), in a rich plain at the foot of the south-western slope of the mountain range of Khimára. In the map prefixed to 'Hobhouse's Travels in Albania' it is placed on a rivulet, the Pistrizza, which flows into the sea at Butrinto or Bucintro, (the antient Buthrotum,) opposite Corfu; but in those prefixed to the Rev. T. S. Hughes's and Dr. Holland's Travels it is not so; and such is the present uncertain state of Albanian geography, that even the site of an important town cannot be exactly laid down. Delvino has a population, according to Mr. Hobhouse, of 8000 persons. Upon the conquest of Albania by the Turks, it was made the residence of a Turkish governor, whose sway extended over the accessible part of the surrounding territory. The governor (whom Mr. Hobhouse describes as a pasha of two tails) was one of those reduced to subjection by Ali Pasha. There is a strong castle at Delvino.

DEMADES, an Athenian orator and demagogue, contemporary with Demosthenes. According to Suidas he was originally a sailor, according to Proclus a fishmonger. He took the part of Philip in the Olynthian affair, and was liberally rewarded by that prince, who received him well when he fell into his hands after the battle of Chæronea. He was mainly instrumental to bringing about the peace between Macedon and Athens, which followed that victory. (Demosth. *de Corona*, p. 320.) When Alexander, in 335 B. C., demanded that the Athenian orators who were opposed to him should be delivered into his hands, Demades induced him to relinquish his claim. (Diod. xvii. 15; Plut. *Dem.*, c. xxiii.) Demades seems to have yielded to the bribery of Harpalus. (Dinarch. c.; Demosth., p. 101.) It appears that he was concerned with Phocion in delivering up Athens to Antipater. (Corn. Nepos, *Phoc. II.*) In 318 B. C. he went on an embassy to Antipater to induce him to remove the garrison from Munychia, and took his son Demeas with him. Unfortunately, a letter which he had written to Perdicas fell into the hands of Cassander, and in revenge for the offensive terms in which Antipater was alluded to in it, that prince put to death the orator and his son. Cicero (*Brut.* 9) and Quintilian (ii. 17, § 13, xii. 10, § 49) assert that he did not write anything; but a fragment of his speech in defence of his twelve years' administration (*ὕπερ τῆς δωδεκαετίας*) is still extant, and Suidas attributes to him a history of Delos, and of the birth of the children of Latona. Pytheas (*in Athen.*, p. 44 F.) describes him as a profligate drunken fellow. He was a great wit, and many of his sallies are recorded.

DEMBEA. [ABYSSINIA; NILE.]

DEMERARA. [GUIANA, BRITISH.]

DEME'TER, CERES, the oldest, and, with a view to the formation of a systematic mythology, by far the most important personage in the Greek polytheism. Her name Demeter (*γῆ, earth, μήτηρ, mother*), or Deo, points to her as a representative of the earth and its productions in the old elementary worship of Greece; and she is invoked by Orpheus (apud Diod. Sic. i. 12) as Mother Earth, the giver of all sorts of riches (*γῆ μήτηρ πάντων Δημήτηρ πλουτοδότειρα*). The title Father is in the same manner given to the air by Lucretius (i. 25),

Postremo pereunt imbres ubi eos pater *Æther*
In gremium matris Terræ præcipitavit;

and the Greeks considered all vegetable productions as the offspring of a union between these two elements. (See the fragment of the *Danaides* of Æschylus in Hermann's *Opuscula*, vol. ii., p. 334.) The mystic union of these two principles, from which all the other deities sprung up, is an invention of the later philosophers. The most remarkable feature which the worship of this deity presents in Greek mythology is her intimate connexion with Bacchus. [BACCHUS.] Without entering into any of the questions agitated with respect to the origin or nature of the Bacchic rites, it may be as well to offer here a brief explanation of this connexion of the two deities, a connexion which seems to have belonged to all the different modifications of the two worships. In the first place, we may remark, that, in the Roman mythology, as well as in the Greek, we continually find duplicate divinities, male and female, and sometimes deities of a doubtful sex. (Niebuhr's *Rome*, vol. ii., p. 100-101, Eng. Tr.; and *Philolog. Mus.*, vol. i., p. 116-117.) Thus the sun-god and the moon-goddess have always been paired together. Now Demeter is not merely the goddess of the earth, in which form she is the wife of *Æther*; she is also the moon (Creuzer, *Symbolik*, iv., 188), as the wife of Bacchus, the sun-god, or wine producer (for the terms were convertible), as in the passage of Virgil referred to under BACCHUS; and she is the queen of the lower world as the wife of the same Bacchus considered as the god of Hell in the mystic worship of the Cabiri, where, according to the scholiast on Apollon. Rhod. i. 917, Axiokersa (who was the same as Demeter or Proserpine) is the wife of Axiokersos or Pluto. (See the passage of Herodotus, quoted under BACCHUS, and compare CABIRI.) At Eleusis these two deities were worshipped with peculiar solemnities; the mysterious secrets which were communicated to the initiated have not been divulged to us; and the many ingenious attempts which have been made to explain their purport have, it is to be feared, been attended with very little success; all that can be said of them with any degree of certainty is, that they were probably a slightly modified adaptation of the Samothracian rites, for the deities appear to have been nearly the same. It does not seem right to infer from the similar relation subsisting between Osiris and Isis in Egypt, and Bacchus and Demeter in Greece (Macrob., *Saturnal.*, i. 2, p. 210; Herod. ii. 144; Plutarch *de Iside*, p. 354 F.), that the worship of these deities was derived from Egypt in particular; still less can we adopt Creuzer's theory of the Indian origin of this religion. It seems more reasonable to conclude that the same causes which might contribute to produce such an elementary worship in the East would have the same effect in Greece; for the constitution of the human mind is much the same in all parts of the world.

Demeter is represented in antient monuments with a basket (*κάλαθος*) on her head, with some ears of corn in her hand, and as seated in a chariot drawn by lions, panthers, or elephants. (Winckelmann's Works, vol. ii. 515, iv. 119.) A collection of her names and epithets is given by Creuzer. (*Symbolik*, vol. iv., p. 301, fol.) The meaning of her Roman name, Ceres, by which she is generally mentioned in English books on mythology, is not known; it may be derived from *c(e)reare, creare*, to produce (Creuzer, *Symbolik*, iv., p. 313); or it is connected with her Cabiric name, Axiokersa, in which case it also signifies the producer; for according to Hesych., *κέρσαι = γαμῆσαι, κέρσης = γάμος* and *μῆξαι = κέρσαι*. On the mysteries of this goddess the reader may consult, in addition to Ouvaroff and Sainte-Croix, the elaborate work of Lobeck, *Aglaophamus; Regiom.* 1830.

DEME'TRIUS PHALE'REUS, an Athenian, the son of Phanostratus, and a scholar of Theophrastus. His earlier years were devoted to the study of philosophy: he first began to take a part in public affairs about 320 B. C. (Diog.

Laert., v. 5—75.) He was condemned to death at the same time with Phocion (317 B. C.) for espousing the Macedonian party, but had the good fortune to escape by flight (Plut. *Phoc.* cxxxv.), and was shortly after made governor of Athens by Cassander. He maintained his authority for ten years, and, according to Strabo (p. 398), Athens was never more happy than under his government. In his administration of affairs he was so popular that 360 statues were erected in his honour; but when Demetrius Poliorcetes came to Athens (307 B. C.) and proclaimed the old democracy, he was obliged to fly a second time, and would hardly have escaped had not his enemy ensured him a safe retreat to Thebes. (Diodor. Sic. xx., 45, 46.) After the death of Cassander (296 B. C.) Demetrius retired to the court of Ptolemy Soter, king of Egypt, where he was received with great distinction, and where he probably wrote most of the numerous works attributed to him by Diogenes. (v. 5—80.) Unfortunately, however, he made an unsuccessful attempt to dissuade his patron from altering the succession to his crown in favour of his children by Berenice. When Ptolemy Philadelphus came to the throne in 283 B. C. he had not forgotten the counsel which would, had it been listened to, have deprived him of his father's preference, and banished the author of it to Busiris, where he soon after died from the bite of an asp. A treatise on rhetoric, ascribed to him, has come down to us, and has been edited separately by Schneider, Altenburg, 1779.

DEMETRIUS POLIORCETES (the city-taker) was the son of Antigonus (one of the successors of Alexander the Great) and Stratonice. He appears to have been born about the year 334, for Plutarch tells us (*Dem.* v.) he was 22 when he was defeated by Ptolemy and Seleucus at Gaza (312 B. C.). Demetrius soon wiped out the disgrace which had attended his first feat of arms by a brilliant victory which he gained over Ciltes, one of the generals of Ptolemy. (Plut., *Dem.* vi.) In the division of Alexander's empire, which shortly followed, it was determined that Greece should be freed from the dominion of Cassander, and this duty Demetrius willingly took upon himself. Demetrius Phalereus then governed Athens as Cassander's deputy, and had obtained great popularity; but when Demetrius Poliorcetes took Munychia and offered a democratical form of government to the Athenians (307 B. C.), the disciple of Theophrastus was glad to owe a safe retreat to Thebes to the generosity of his namesake. In the following year Demetrius gained a great naval victory over Ptolemy, and conquered the isle of Cyprus, in consequence of which his father Antigonus assumed the title of king. (Plut. *Dem.* xvii., xviii.) In 304 Demetrius laid siege to Rhodes, but, although he showed all the resources of his genius in inventing new and extraordinary machines for taking the city, he was unable to make himself master of it, and, after a year's siege, he formed an alliance with the Rhodians against all persons, with the exception of Ptolemy. (Plut. *Dem.* xxi.) Demetrius then returned to Greece, forced Cassander to raise the siege of Athens, and pursued him to Thermopylæ: after this he took Sicyon by surprise, and then Corinth and Argos, where he married Deidamia, sister of Pyrrhus, king of Epirus. Cassander was willing to make peace, but Antigonus showed so little moderation that the other successors of Alexander were induced, through fear of the consequences of his ambition, to form a coalition against him. Antigonus met his enemies at Ipsus, in Phrygia, and fell in the battle. (Diod. xxi.; Plut. *Dem.* xxviii.—xxx.) Demetrius escaped from the defeat with 9000 men to Ephesus, whence he passed over to the Cyclades, and, being excluded from Athens, sailed for the Chersonese. While he was there engaged in laying waste the lands of Lysimachus, Seleucus sent to him to demand his daughter Stratonice in marriage, a proposal to which he readily agreed. In 299 B. C. he laid siege to Athens, which was under the dominion of the tyrant Lachares. The city soon surrendered, and was treated with great kindness by the conqueror. (Plut. *Dem.* xxxiv.) The quarrel of Alexander and Antipater, the two sons of Cassander, gave him an opportunity of getting possession of Macedon, which he easily accomplished after having put to death Alexander, who had called him in to assist him against his brother. (294 B. C.) Although master of the greater part of Greece, he was eager to get possession of the whole, and attacked and took Thebes. But his popularity was now on the wane, and he was easily driven from the throne of Macedon by Pyrrhus the Epirote, in 287 B. C., whose good qualities had

become known to the subjects of Demetrius. (Plut. *Dem.* xlv.) Shortly afterwards he fell into the hands of Seleucus, whose kingdom he had invaded, and was detained by him in honourable confinement till his death in 283 B. C. This celebrated man was so eminently handsome in his person that sculptors and painters always fell short of his beauty. He was much given to debauchery, and is said to have shortened his life by his excesses.

[Coin of Demetrius Poliorcetes.]

British Museum. Actual Size. Silver. Weight $260\frac{8}{10}$ grains.

DEMETRIUS SOTER, king of Syria, the son of Seleucus Philopater, passed his youth at Rome as a hostage. He effected his escape, partly through the assistance afforded him by the historian Polybius, and mounted the throne of his ancestors about 161 B. C. He contended in vain with the Maccabees, who then ruled over Judea, and died valiantly fighting against Alexander Balas about B. C. 150.

[Coin of Demetrius Soter.]

British Museum. Actual Size. Silver. Weight $256\frac{3}{10}$ grains.

DEMETRIUS NICATOR was the son of Soter. Having been sent to Cnidos, towards the end of his father's reign, he did not fall into the hands of the successful usurper Bala, and with the assistance of the king of Egypt, whose daughter Cleopatra he had married, soon possessed himself of his father's throne. As, however, he gave himself up, after a while, to luxury and indolence, and did not attend to the duties of his station, his numerous enemies contrived to expel him from his kingdom, and he remained for some time in the hands of the Parthians, upon whom he had

[Coin of Demetrius Nicator.]

British Museum. Actual Size. Silver. Weight $260\frac{2}{10}$ grains.

ventured to make war. While still in captivity he married a daughter of Mithridates, the Parthian king; and his former wife Cleopatra formed a union with his brother Antiochus, who became king of Syria in his absence, and fell in battle with the Parthians. Phraates, before this event happened, had released Demetrius, in order that he might divide his brother's party, and he consequently regained his kingdom after the death of Antiochus. But Demetrius governed Syria no better than before his captivity. He was again expelled by another usurper, and was assassinated by the orders of his wife Cleopatra in a temple at Tyre, where he had taken refuge, B. C. 126.

DEMETRIUS of Bactria. [BACTRIA.]

DEMI-LUNE. [RAVELIN.]

DEMOCRACY (*δημοκρατία*) a word taken from the Greek language, like aristocracy, oligarchy, monarchy, and other political terms.

The third book of Herodotus (chap. 80—82) contains what we may consider as the views of the oldest extant Greek historian on the merits and defects of the three respective forms of government as they are called, democracy, oligarchy, and monarchy. It would be difficult to extract from the chapters referred to an exact definition of democracy, but still we learn from them what were considered to be essentials; first, complete political equality (*ισονομία*); secondly, the election of magistrates by lot (*πάλω*) (which, coupled with the first condition, implies that public offices must be accessible to all); thirdly, responsibility or accountability in public functionaries (*ἀρχὴ ὑπεύθυνος*), which implies a short term of office and liability to be ejected from it; fourthly, the decision by the community at large of all public matters (*τὸ βουλευόμενα πάντα ἐς τὸ κοινὸν ἀναφέρειν*).

It is unnecessary to mention the merits and defects of a democracy as pointed out in the above chapters, the defects being only certain consequences supposed to flow from, and the merits certain advantages incident to, a democratical institution, and neither being essentially parts of the fundamental notion of a democracy.

In forming a notion of a democracy as conceived by the Greeks, and indeed in forming any exact notion of a pure democracy, it is necessary to consider a small community, such as a single town with a little territory, and to view such a community as an independent sovereignty. The institutions which in modern times have approached most nearly to the form of a pure democracy are some of the Swiss cantons. The boroughs of England, as existing in their supposed original purity, and as partly restored to that supposed original purity by the late Municipal Corporation Act, may help to explain the notion of a democracy, though they are wanting in the necessary element of possessing sovereignty. Further, to conceive correctly of a Greek democracy and of some of the democracies of the North American Union, it must be remembered that the whole community in such States consisted and consists of two great divisions, freemen and slaves, of whom the latter form no part of the political system.

In most Greek communities we find two marked divisions of the freemen, the 'few' (*ὀλίγοι*) or 'rich' (*δυνατοί*, *πλούσιοι*), and the 'many' (*οἱ πολλοί*, *ὁ δῆμος*) or 'not rich' (*ἄποροι*), between whom a fierce contest for political superiority was maintained. This contest would often end in the expulsion of the 'few,' and the division of their lands and property among the many; sometimes in the expulsion of the leaders of the 'many,' and the political subjugation of the rest. Thus the same state would at one time be called a democracy; at another, an oligarchy, according as one or the other party possessed the political superiority; a circumstance which evidently tended to confuse all exact notions of the meaning of the respective terms used to denote the respective kinds of politics. Under the circumstances described, what was called an oligarchy might perhaps be appropriately so called; what was called a democracy was not appropriately so called, even according to the notions entertained by the Greeks themselves of a democracy; for such so-called democracy was only a fraction of the community that had obtained a victory over another fraction of the community, less numerous and individually more wealthy: for the 'few' and the 'rich' were necessarily united in idea; it being, as Aristotle remarks, incident to the 'rich' to be the 'few,' and the rest to be the 'many.'

Aristotle felt the difficulty of defining what a democracy is. He observes (*Politik.* iv. 4) that neither an oligarchy nor a democracy must be defined simply with reference to the number of those composing the respective bodies: if a considerable majority, he says, are rich, and exclude the remaining body of freemen, who are poor, from political rights, this is not a democracy. Nor, on the contrary, if the poor, being few, should exclude the rich, being more numerous, from all political power, would this be an oligarchy. Such a supposition as the latter is impossible in a sovereign community, except during a short period of revolutionary change; but it is not an impossible supposition in a case where a community, not being sovereign, is governed by a constitution or charter granted by the sovereign power. In

the borough of Malmsbury (*Report on Municipal Corporations*, vol. i., p. 77), at the time of the Report, a very small number of the population formed the ruling body: this body filled up vacancies in their own number, was irresponsible to the inhabitants, and chiefly composed of labourers without education, and of the least instructed class of retail tradesmen. The then alderman, the chief magistrate of the town, was a pig-killer, and scarcely able to write his name. Such an anomalous political constitution requires a new and appropriate name.

Aristotle, after some preliminary remarks, concludes by defining a democracy to be, when the freemen and those not the rich, being the majority, possess the sovereign power; and an oligarchy, when the rich and those of noble birth, being few, are in possession of the sovereign power. This definition of an oligarchy necessarily implies that the majority are excluded from participating in the sovereign power. It might be inferred, on the other hand, that in this definition of a democracy the few are excluded from the sovereign power; and such in this passage should be the meaning of the author, if he is consistent with himself. In another passage (iv., 4), where he is speaking of the different kinds of democracy, he speaks of the first kind as characterized by *equality* (*κατὰ τὸ ἴσον*): and by this equality he understands 'the not rich having no more political power than the rich, neither body being supreme, but both equal, and all participating equally in political power.' Such in fact approaches very near the exact notion of a pure democracy, or at least a democracy as pure as we have any example of; for women, persons of unsound mind, males not adult, and slaves, are excluded from political power even in democracies.

A pure democracy then is where every male citizen, with the exceptions above mentioned, forms an equal and integral part of the sovereign body; or, as Aristotle expresses it, the democracy is 'monarch, one compounded of many.' This is the fundamental notion of a democracy: every other institution incident to or existing in a democracy is either a necessary consequence from this notion or a positive law enacted by the universal sovereign.

Thus it is absolutely necessary, in order that a democracy should exist and continue to exist, that the whole body should recognize the principle that the will of the majority must always bind the minority. It seems also necessary for the whole body to admit the principle that every member of the sovereign power shall express his opinion without fear, control, or any influence, that is, secretly. Every freeman being an equal part of the sovereign, has no responsibility, such as some persons dream of: the many who compose the sovereign are no more responsible than when the sovereign is one, and the notion that the vote of those who possess sovereign power should be open and notorious, on the ground of their being responsible, is inconsistent with the notion of their possessing sovereign power. The only way in which the universal sovereign can be so made responsible to a positive morality (for there is nothing else that such sovereign can be made responsible to) must be by the universal sovereign making such open voting a constitutional rule, which rule the same body that made may repeal when it pleases. Such rule, however, being inconsistent with the free exercise by each individual of his share of sovereignty, would be an act of suicide in the body politic.

If the democracy consider a constitution [CONSTITUTION] to be useful for carrying into effect the will of the sovereign, such constitution, when made by the expressed will of the majority, whatever may be the terms of such constitution, does not affect the principle of the democracy. Such constitution can be altered or destroyed by the same power that made it. If a representative body is necessary for effecting the purposes of the sovereign, such body may be elected and invested with any powers by the sovereign body, always provided that the representative body is responsible to the sovereign whose creature it is. Whatever institutions are created, and whatever powers are delegated by the sovereign many, the principle of pure democracy still exists so long as every individual and every body of individuals who exercise delegated power are responsible to the sovereign body by whom the power is delegated. Hence if property be made a qualification for certain offices, as in one of the forms of democracy mentioned by Aristotle, by the universal sovereign, such requisite qualification does not in itself alter the nature of the democracy,

being only a rule or law fixed by the sovereign. It is however a rule or law of that class, the *tendency* of which, where the sovereign power is possessed by the many, is to undermine and ultimately destroy the power that made it.

Experience has shown that even where the universal people are sovereign, if the political community is large and spread over a great surface, every delegation of power, however necessary, is accompanied with danger to the existence of the sovereign power. The more complicated the machinery of administration becomes, and the more numerous are the administering bodies interposed between the sovereign and the accomplishment of the object for which the sovereign delegates part of his power, the greater is the risk of those who have had power delegated to them making themselves the masters of those who have conferred the power. In a democracy the great problem must be to preserve unimpaired and undisputed the vital principle of the sovereign power being in all and in every individual, and to combine with this such a system of delegated powers as shall in their operation always recognize that principle to which they owe their existence.

Of all the forms of government only two seem capable of exact definition, monarchy and democracy, and those two only seem to rest on any clear and intelligible principle. Forms of government which lie between these two have received the various names of aristocracies, oligarchies, &c., but no one has yet succeeded in explaining what an aristocracy is, or to what portion of a community political power must be limited in order to constitute an oligarchy.

DEMOCRITUS was born at Abdera in Thrace, or, according to some, as we learn from Diogenes Laertius (ix. 34), at Miletus, in the year 460 B.C. He was thus 40 years younger than Anaxagoras, and eight years younger than Socrates. He received his first lessons in astrology and theology from some Magi, who had been left with his father by Xerxes when passing through Abdera to the invasion of Greece; and he is said to have been afterwards a hearer of Leucippus and Anaxagoras. That he heard Anaxagoras is doubtful, but, if he did, it must have been while Anaxagoras was at Lampsacus; for when this philosopher was banished from Athens (450 B.C.) Democritus was only ten years old. Democritus appears to have been a great traveller. He is said to have visited Egypt, that he might learn geometry from the Egyptian priests; to have been in Persis, and with the Gymnosophists in India, and to have penetrated into Ethiopia. He sojourned for some time at Athens; but from contempt of notoriety, as it is said, was known to nobody in that city. It is for this reason that Demetrius Phalereus, as cited by Diogenes Laertius (ix. 37), contended that Democritus had never visited Athens. One result of his extensive travels was, that he expended all his patrimony, which is said to have exceeded 100 talents. Now, it was a law of his country, that any one who spent his whole patrimony should be refused burial in his native land; but Democritus, having read his chief work aloud to his fellow-citizens, so impressed them with an admiration of his learning, that he not merely obtained a special exemption from the above law, but was presented with 500 talents, and was, on his death, buried at the public expense. (Diog. Laert. ix. 39.) A story substantially the same, though varying somewhat in detail, is given in Athæneus (iv. p. 198). He is said to have continued travelling till he was 80 years old. He died in the year 357 B.C. at the age of 104. There is a story of his having protracted his life for three days after death seemed inevitable, by means of the smell of either bread or honey, and in order to gratify his sister, who, had he died when first he seemed likely to die, would have been prevented from attending a festival of Ceres. (Diog. Laert. ix. 43; Athæn. ii. 7.)

Democritus loved solitude, and was wholly wrapt up in study. There are several anecdotes illustrative of his devotion to knowledge, and his disregard of everything else. They conflict somewhat with one another in their details; but accuracy of detail is not to be looked for, and, tending all to the same point, they prove, which is all that we can expect to know, what character was traditionally assigned to Democritus. Cicero (*de Fin.* v. 29) speaks of him as, like Anaxagoras, leaving his lands uncultivated, in his undivided care for learning; while, as an instance of how these stories conflict, Diogenes Laertius represents him as having, on the division of the paternal estate with his two brothers, taken his own share entirely in money, as being more convenient

than land for a traveller. Valerius Maximus (viii. 7) makes him show his contempt for worldly things by giving almost the whole of his patrimony to his country. He is said too to have put out his eyes, that he might not be diverted from thought; but Plutarch (*de Curiositate*, p. 521, C) rejects this story, and explains how it might have arisen. It was Democritus who, struck with the ingenuity displayed by Protagoras in the tying up of a bundle, raised him from the humble condition of a porter, and gained him for philosophy.

Democritus followed Leucippus at a very short distance of time, and preceded Epicurus by somewhat less than a century, as an expounder of the atomic or corpuscular philosophy. [ATOM.] He viewed all matter as reducible to particles, which are themselves indivisible (hence called *atoms*), and which are similar in form. He included mind under the head of matter, recognizing only matter and empty space as composing the universe, and viewed mind as consisting of round atoms of fire. (Aristot. *de Anim.* 1, 2.) Arguing that nothing could arise out of nothing, and also that nothing could utterly perish and become nothing, he contended for the eternity of the universe, and thus dispensed with a creator. He further explained the difference in material substances (mind, as has been said, being one of them) by a difference in the nature and arrangement of their component atoms, and all material (including mental) phenomena by different motions, progressive or regressive, straight or circular, taking place among these atoms and taking place of *necessity*. Thus the cosmology of Democritus was essentially atheistic.

In psychology he explained sensation, as did Epicurus after him, by supposing particles, *εἰδωλα*, as he called them, or sensible images, to issue from bodies. He also thought to explain men's belief in gods by the supposed existence of large images of human form in the air. In moral philosophy he announced nothing more than that a cheerful state of mind (*εὐεστὴ, εὐθυμία*) was the one thing to be sought after. The manner in which the follies of men affected him, and from which he derived his name of the 'laughing philosopher,' is well known. (Juv. x. 33—55.)

A list of the very numerous writings of Democritus is contained in Diogenes Laertius (ix. 46—49). They are arranged under the five principal heads of ethics, physics, mathematics, general literature, and arts; and there are besides a few of miscellaneous character. The list, classified in the same manner, and enriched with critical remarks, is given in Fabricius (*Bibliotheca Græca*, ed. Harles. vol. ii., p. 634—641). The reader will see in this work a list of the writings wrongly attributed to Democritus, and statements of the grounds on which they are severally pronounced spurious; among them are the writings on magic which are spoken of by Pliny (*Hist. Nat.* xxx. 1), and considered by him as genuine.

For an account of the philosophy of Democritus the reader is referred to Hill, 'De Philosophia Epicurea, Democritea et Theophrastea,' Genev., 1669; Ploucquet, 'De Placitis Democriti Abderitæ,' Tübing. 1767; Cudworth's 'Intellectual System,' chap. i.; and to the common histories of philosophy; and for general information concerning his life to Bayle's 'Dictionary,' and Fabricius' 'Bibliotheca Græca,' ed. Harles. vol. ii. p. 628.

DEMOISELLE. (Zoology.) [GRUIDÆ.]

DEMOIVRE, ABRAHAM, was born at Vitry in Champagne, on the 26th of May, 1667, and was descended of an antient and honourable family of the French Protestant church. The revocation of the edict of Nantes in 1685 compelled him to leave his native country, and, like a great number of the refugees created by that revocation, he settled in England, choosing for the field of his efforts the metropolis.

He appears at the earliest period to which any account of him reaches to have devoted himself to teaching mathematics, as the surest means of obtaining a subsistence. He also, though he was not the first who adopted that plan, read lectures on natural philosophy: but it does not appear that his attempts in this way were very successful, he being neither fluent in the use of the English language, nor a good experimental manipulator.

The popularity, as a book to be talked about, of Newton's great work, compelled Demoivre to enter upon the study of it; and there is no doubt that he was one of the few who at that time were able to follow the illustrious Newton in the course of his investigations. Demoivre's

power, however, lay in pure mathematics of the kind now called analytical; for in all his writings there is scarcely a trace either of physical or geometrical investigation to be discerned. His writings on analysis abound with consummate contrivance and skill; and one at least of his investigations has had the effect of completely changing the whole character of trigonometrical science in its higher departments. [TRIGONOMETRY.]

At a comparatively early period of his residence in London he was admitted to the society of Newton and his immediate circle of personal friends; and many instances of the regard with which he was treated are current amongst the traditions which have reached our own time. This of course led to an intimacy with the leading mathematicians of that period; and his great talents soon obtained his election into the Royal Society, as well as, ultimately, those of Paris and Berlin. The estimate formed of his abilities, acquirements, and impartiality, is proved by his being nominated as a fit person to decide on the rival claims of Leibnitz and Newton to the invention of the method of fluxions.

Demoivre lived to the advanced age of more than eighty-seven; but as he outlived most of his early associates and friends, his circumstances became greatly reduced. He is said to have sunk into a state of almost total lethargy, the attacks of which often lasted for several days; and his subsistence was latterly dependent on the solution of questions relative to games of chance and other matters connected with the value of probabilities, which he was in the habit of giving at a tavern or coffee-house in St. Martin's Lane. He died on the 27th of November, 1754.

Demoivre's writings, we have already remarked, are distinguished by considerable originality of character. His separate publications are as follows:—

1. *Miscellanea Analytica, de Seriebus et Quadraturis*, 1730, 4to. This work contains several very elegant improvements in the then known methods of termination of series, as well as some new methods.

2. *The Doctrine of Chances, or the Method of Calculating the Probabilities of Events at Play*, 1718, 4to. This work was dedicated to Sir Isaac Newton: it was reprinted in 1738, with considerable alterations and additions. A third edition was afterwards published, differing little in anything of consequence from the second.

3. *Annuities on Lives*, 1724, 8vo. A work on the same subject, published by the distinguished Thomas Simpson, in 1742, in which some well-deserved compliments to Demoivre were introduced, led our author to publish a second edition of his work; and it is to be regretted that he was induced to insert some harsh reflections on Simpson's work, which were as unfounded as they were uncalled for by the manner in which Simpson had treated his predecessor's first edition. Simpson, however, replied to it in an appendix to his work in the following year, 'containing some remarks on a late book on the subject, with answers to some personal and malignant representations in the preface thereof.' The only excuse that can be urged for Demoivre in this matter is, that he was an old man, that he considered the domain his own, and Simpson as a mere poacher on it, and that he was under the influence of men who wished to crush the rising genius and talents of a man like Simpson, who had not been born to the advantages which enabled him to obtain a regular academical education. Demoivre, notwithstanding his age, had the good sense to see that he had attacked a man with whom he could not cope; but still pride prevented his making any apology to his younger competitor. In 1750 he published a third edition of his work, in which he merely omitted the offensive reflections of his former preface; and here the dispute seems to have terminated. Demoivre also published a considerable number of papers in the 'Philosophical Transactions.' There is not one of these which is not of sterling value on the subjects of which they treat.

DEMOIVRE'S HYPOTHESIS. An hypothesis on the duration of human life, formed by Demoivre, as he informs us in the preface of his *Treatise on Annuities*, some years after the publication of the first edition of his *Treatise on Chances*, on the inspection of Halley's Breslaw Tables. Observing that the decrements of life at the middle ages were very nearly uniform, Demoivre made an extension of this law to the whole of life, not thereby intending to assert that any such principle was correct for childhood and old

age, but simply that the effect of the error upon the value of annuities at the middle ages of life would be trivial. The hypothesis is as follows:—*of eighty-six persons born, one dies every year, till all are extinct.* The remainder of eighty-six years, at every age, Demoivre called the *complement of life*. The half of the complement of life is the average duration (commonly called the expectation); and the peculiarity of Demoivre's hypothesis is, that, according to it, every person has an even chance of living the average time of people of his age, which is not true of other tables. The Northampton Tables certainly do nearly coincide with this law at the middle periods of life, but the Carlisle and most other tables differ materially from it. Thus at twenty years of age, according to the Carlisle Tables, the *average duration* is to the age of sixty-one and a half, while each individual aged twenty *has an even chance* of living to be about sixty-five years of age.

The following table (left hand) shows the number of persons out of ten thousand who may be expected to die in the year next following their attaining the age marked in the first column, according to this hypothesis, the Northampton and Carlisle Tables, and the Belgian Tables of M. Quetelet:—

Age.	Hypo- the- sis.	North- amp- ton.	Car- lisle.	Bel- gian.	Age.	Hypo- the- sis.	North- amp- ton.	Car- lisle.
10	132	92	45	88	10	19.9	20.7	23.5
20	152	140	71	120	20	18.5	18.6	21.7
30	179	171	101	126	30	16.8	16.9	19.6
40	217	209	130	144	40	14.8	14.8	17.1
50	278	284	134	183	50	12.5	12.4	14.3
60	385	402	335	325	60	9.7	9.8	10.5
70	625	649	516	680	70	6.4	6.7	7.1
80	1667	1343	1217	1425	80	2.3	3.8	4.4

The second table shows the values of annuities on lives of the ages in the first column, at three per cent., in years' purchase. Practically speaking, then, the celebrated Northampton Tables agree with Demoivre's hypothesis in their money results, though by no means exhibiting the same physical law of life.

It must be observed of Demoivre's hypothesis, that any one which supposes uniform decrements throughout is entitled to the name, whether the limit of life be eighty-six years or not. Conformably to this view, the modification which best represents the Carlisle Tables would be, that, of 128 persons born, one dies every year; a supposition which would be as much in excess on one side, for old lives, as that of eighty-six is in defect, but which would represent the Carlisle Tables from twenty to fifty years of age as well as the use of eighty-six does the Northampton Tables.

DE'MONA, VAL DI, one of the three old divisions of Sicily, which comprised the north-east part of the island, is now divided into the two intendenza, or provinces of Catania and Messina. A great part of the Val di Demona is occupied by the mass of *Ætna*. Near the north coast, and parallel with it, is a continuation of mountains, of which Mount Madonia, the antient Nebrodes, near Cefalu, and Mount Dinamari, near Messina, are the highest summits. The Val di Demona is the most woody part of all Sicily. Besides the extensive forests which encircle *Ætna*, there is near the north coast a large forest, which, under the names of Bosco di Caronia, Bosco di Castro, and Bosco di Cutò, extends more than 20 miles in length from east to west. The boundaries of the Val di Demona were, to the south, the river Giarretta, which divided it from Val di Noto, and, to the west, the small river Della Rouella, which separated it from the Val di Mazzara. The district of Cefalu, which is the most western part of the Val di Demona, forms now part of the intendenza or province of Palermo. [ÆTNA.]

DEMONSTRATION. The old use of this word has been alluded to in the life of COPERNICUS. It meant any manner of *showing* either the connexion of a conclusion with its premises, or that of a phenomenon with the asserted cause. Thus we find it asserted by an early writer that the system of Copernicus, *though false*, gave *truer* demonstrations of the celestial motions than any other: meaning that those motions could be more easily shown to be a necessary consequence of the hypothesis cited than of any other. It is very important, in reading the old English writers, to remember this use of the term.

Demonstration now means only that process by which a result is shown to be a necessary consequence of the premises from which it is asserted to follow, on the supposition that those premises are admitted, either as matter of fact, or of intuitive evidence, or of previous demonstration. Thus the 47th proposition of the first book of Euclid demonstrates a certain property of a right-angled triangle, on the supposition—1, that all the preceding propositions are true; 2, that the axioms used in geometry, whether expressed or implied, are true also. It makes the consequence as certain as the premises, by means of the indubitable character of the connecting process. This strict use of the term demonstration belongs to the science of logic, which is the art of demonstrating from premises, without reference to the truth or falsehood of the premises themselves.

But in common life the word demonstration means any sort of reasoning which the party using the term chooses to call proof. 'I consider it as demonstrated,' means the same thing as 'evidence has been offered which makes it so probable to me that I am willing to act upon that evidence.' Most minds have no idea of a middle state; they either absolutely receive or absolutely reject: so that in fact demonstration comes with any degree of balance of evidence on one side or the other. It is easy to admit that in common life high probability is the ground of assent, and that it never can be otherwise: but there is mischief in the use of the same term both for logical inference and for its mixture with matters of guess or feeling, or unassisted perception. The logician might consent to abandon the word demonstration for popular use, and to adopt another: but it would result, that the new word, whatever it might be, would immediately be seized by those who confound what is commonly called argument with what is actually demonstration. Whatever may be the strongest term in use, it will be adopted by strong assertors: nor will he who has shown probable reason, however great, for the adoption of a result of argument, be satisfied unless his conclusion be received as *certain*. What we have here said refers entirely to the use of the word demonstration: the fallacy to be feared is the placing in the result of it, in one sense, the degree of confidence which is only obtained by confounding that sense with another. Two parties, both convinced that a conclusion has a high degree of evidence, dispute whether the evidence *amounts to demonstration*. To settle this point, they sift the evidence most minutely, and perhaps entirely forget to inquire whether they mean the same thing by the word demonstration.

DEMONSTRATIONS, in military affairs, are operations of any kind which may be performed for the purpose of deceiving the enemy respecting the measures which it is intended to employ against him.

They consist in displaying an apparent activity in forming or repairing a road, or in sending provisions or stores to a particular place, as if preparatory to a march of troops in that direction; in marking out ground as if for an encampment; and in detaching bodies of troops to make false attacks. Such demonstrations are made chiefly with a view of inducing an enemy to divide his forces, and thus weaken his line at points against which the real movement or attack is intended to be directed.

In order to succeed, however, in these demonstrations, they should be made with great precaution, that they may have every appearance of indicating a serious enterprise: even the troops who are to execute them should be unacquainted with the object in view, lest a deficiency of energy should betray the secret to the enemy, who must be supposed to be on his guard against such attempts, and who may consequently take measures to render them useless.

DEMOSTHENES was born probably about B.C. 384, Ol. 99. 1. He was the son of Demosthenes, an Athenian citizen of the demus Pæania, who carried on the trades of cutler and cabinet-maker, and of Cleobule, the daughter of Gylon. This Gylon, who had been governor of Nymphæum, an Athenian settlement in the Tauric Chersonesus, betrayed it to the Scythians, and, afterwards taking refuge with their chief, married a Scythian woman, who was the maternal grandmother of Demosthenes. This impurity of blood and the misconduct of Gylon, his maternal grandfather, formed a theme for the taunts of Æschines. (*Oration against Ctesiphon*.) There is a well-known allusion in Juvenal to the trade of Demosthenes the elder (x. 130):

Quem pater ardentis massæ fuligine lippus,
A carbone et forcipibus gladiosque parante
Incude et luteo Vulcano ad rhetora misit.

The point of the satirist is however somewhat lost, when we remember that Plutarch applies to the father a term (*καλοκαγάρτος*) which expresses all that can be said to the advantage of a man, and that he had two manufactories (*ἐργαστήρια*) containing on the whole more than 50 slaves. (Creuzer, *View of Slavery in Rome*, note 40, and the *Orations of Demosthenes against Aphobus*.)

Demosthenes the elder died when his son was seven years old, leaving him and a sister, younger than himself, to the care of three guardians, Aphobus and Demophon, his first cousins, and Therippides, a friend. The property left by him amounted to 15 talents, above 3000*l.* in specie, taking silver as the standard. The guardians, however, as we learn from Demosthenes himself, disregarded all his father's injunctions, and, while they neglected to improve the property of which they were trustees, embezzled nearly the whole of it. (*Orations against Aphobus*.) Plutarch states that they also deprived Demosthenes of proper masters. He himself, however, in a passage where it is his object to magnify all that concerns his own history, boasts of the fitting education which he had received. (*Orat. on the Crown*, p. 312.) He is said to have studied philosophy under Plato, and to have been a pupil of Eubulides of Miletus.

Having heard Callistratus plead on one occasion, he was fired by that orator's success with ambition to become an orator himself, and he accordingly received instructions in the rhetorical art from Isæus. Cicero (*De Oratore* ii. 94) mentions Demosthenes as one of those who came forth from the school of Isocrates: Plutarch, on the other hand, expressly states that he was not a pupil of Isocrates, and goes out of his way to invent reasons why Demosthenes should have preferred the instructions of Isæus. We assume however that Isæus was his principal instructor, in accordance with the testimony of the various biographers. (Libanius, Zosimus.) We are told that many suspected the speeches against his guardians to have been written, while others said that they were corrected, by Isæus, partly because Demosthenes was so young when they were delivered, and partly because they bore marks of the style of Isæus. He is said to have taken lessons in action from Aristonicus, a player.

The physical disadvantages under which Demosthenes laboured are well known, and the manner in which he surmounted them is often quoted as an example to encourage others to persevere. It should be observed, however, that the authority for some of these stories is but small, and that they rest on the assertions of writers of late date. He was naturally of a weak constitution: he had a feeble voice, an indistinct articulation, and a shortness of breath. Finding that these defects impaired the effect of his speeches, he set resolutely to work to overcome them. The means which he is said to have taken to remedy these defects look very like the inventions of some writer of the rhetorical school, though Plutarch (*Demosth.* x.) quotes Demetrius the Phalerian as saying that he had from the orator's own mouth what Plutarch has stated in the chapter just referred to. Among these means we hear of climbing up hills with pebbles in his mouth, declaiming on the sea shore, or with a sword hung so as to strike his shoulder when he made an uncouth gesture. He is also said to have shut himself up at times in a cave under ground for study's sake, and this for months together.

Having been emancipated from his guardians, after a minority of ten years, he commenced a prosecution against them to recover his property. Estimating his losses at 30 talents (inclusive of ten years' interest), he sued Aphobus for one-third part, and gained his cause, without however succeeding in obtaining more than a small part of his money. This took place B.C. 364, when he was in his 20th year, or, as he says himself (*Mid.* 539, § 23), when he was quite a boy; but the extant orations against his guardians are evidently not the work of a youth of that age, as a careful perusal of these orations will clearly show. He subsequently adopted the profession of writing and delivering, as a hired advocate, speeches for persons engaged in private and public causes—a practice which was now generally adopted by the Greek orators, and was attended with considerable profit. His first speech on a public occasion was made in 355 B.C., in which year he wrote the speech

against Androtion, and wrote and delivered that against Leptines.

Of his speeches relating to public concerns, there are three which have a direct bearing on his personal history: the speech against Midias, that concerning Malversation in the Embassy, and that in behalf of Ctesiphon, or, as it is commonly called, the 'Oration on the Crown.' The two last are briefly noticed under the article *Æschines*. [*ÆSCHINES*.] With reference to the first, it should be premised that, in the year 351 B.C., Demosthenes voluntarily undertook the expensive office of Choragus, and that, during the performances at the Dionysia, when discharging his duties, he was insulted and struck by Midias. Demosthenes brought an action against Midias for assaulting him in the performance of what was regarded as a religious duty, and thus Midias was involved in a prosecution for sacrilege. Demosthenes obtained a verdict. The extant oration against Midias was written three years afterwards.

The first speech on a public affair that remains, and probably the first which Demosthenes published, is that on the *Symmoriz*, which was delivered B.C. 354. A few words will be necessary to explain the state of parties at the time.

About ten years previous to this oration the power of Sparta had been broken by Thebes, who in her turn sank into inactivity after the death of her great general Epaminondas in the battle of Mantinea, B.C. 362; three years after this time Philip of Macedon began his reign. His first step, after defeating two other claimants to the throne and compelling the Pæonians and Illyrians to submission, was to possess himself of several Greek colonies to the south of Macedonia, and to interfere in a war of succession then going on in Thessaly. Athens, not yet recovered from the effects of the Peloponnesian war, had been engaged from 357 to 355 B.C. in a war with her allies, Rhodes, Chios, Cos, and Byzantium, which ended in their throwing off the yoke under which she had held them, about a year before the delivery of the oration on the *Symmoriz*. There were, as usual, two parties in Athens. With one of these, which was headed by Phocion, Philip had an intimate connexion, and this party was not unfavourable to his designs, either through want of energy, or from believing that they would do Greece no injury. The other party, called by Mitford 'the War Party,' was headed by a profligate general named Chares, and was that to which Demosthenes was afterwards attached.

Perhaps the most important event of the time was the war occasioned by the seizure of the temple of Apollo at Delphi by the Phocians. There had been a dispute as to the sacred land, which had long belonged to Phocis, and the Amphictyonic council asserting their claim, Philomelus the Phocian seized the temple, and its treasures were freely used in the war, which continued till 346. It was through this war that Philip contrived to identify his interests with that of the Amphictyons at large, and at last to be elected their leader, and hence we must generally consider the leading parties in the struggle between Philip and Demosthenes to have been the Amphictyonic states and Macedon on the one side, against Athens and occasionally Persia on the other; while we must remember that in Thebes, the principal Amphictyonic state, there was a strong party against Philip, as in Athens there was one equally strong for him.

Under these circumstances, Demosthenes made his oration on the *Symmoriz*, which in part relates to a question of finance, but more particularly to a scheme then on foot for sending Chares with an armament into Asia against the Persians; a project utterly preposterous, as Athens had enough to do to hold her ground against the refractory colonies and subject states, without engaging in other undertakings. Against this measure Demosthenes directed his eloquence with success, and this may be considered the beginning of his struggle with Philip, for the Macedonian cause would have gained by any loss which Athens might sustain. About a year after, Philip began to take an active part in the affairs of the Sacred War, as that in Phocis is usually called. He defeated the Phocian alliance, and only retired, as it should seem, to avoid any rupture with Athens, such as might preclude all hope of adding her to the number of his auxiliaries. At this juncture Demosthenes, who had been opposed to the former war, joined Chares, and delivered his first Philippic.

The motive of this apparent change of opinion is evident: on the former occasion, he saw that war would have been the dispersion of strength which was needful for a nearer struggle; now, he saw that the time for that struggle was come, and knew that, to be effectual, Athens must direct it. (*Oration on the Crown*, p. 249.) But Athens, however powerful when roused, had lost much of that spirit of individual bravery which characterized her in the best times of her history. The exhortations of Demosthenes failed in producing the desired effect; nor was it till Philip had defeated Kersobleptes the Thracian, whom it was the interest of the Athenians to support as his rival, that they considered themselves compelled to commence military operations against him.

This was at last done by sending successive expeditions to Olynthus, a maritime town near the isthmus of Pallene, and by an inroad into Eubœa, under the direction of Phocion, by means of which the Macedonian influence was lessened in that island. The former step was however the more important, as Olynthus was a place of strength, and was looked on with great jealousy by Philip.

Olynthus had made alliance with Athens contrary to a compact with Philip, and although well enough supplied with arms and men, it required the assistance of Athenian soldiers. To provide for these expeditions, Demosthenes, in his Olynthiac orations, advised the application of the money appropriated to the public festivals, and in so doing was opposed by Phocion: this has been made a subject of petty attack by Mitford, who believing the oration *περὶ Συντάξεως* to be genuine, accuses Demosthenes of inconsistency, as in that oration the speaker opposes a similar measure. And yet taking Mitford's own ground, we should rather admire the steadiness of purpose which made him oppose his own friends when he thought it for the public good, and the discrimination which told him that the time and opportunity for effort were now come.

In spite however of the exertions of Demosthenes, Olynthus was taken by Philip in the spring of 347 B.C., and we may here remark, that the frequency of failure in action against an enemy who was constantly outdone in negotiation, is only to be accounted for by the fact, which Mitford notices, of the decline in personal bravery in a nation long used to conquest.

Early in the succeeding year Demosthenes, with *Æschines* and eight or nine others, went on an embassy to Philip, to treat of peace. According to *Æschines*, he exhibited great want of self-possession on this occasion. If this were the case, it is surely not too much to attribute it to a consciousness that he had departed through fear of present danger from his one great object of opposition to Philip, who, even during the settlement of preliminaries, seized on several Thracian towns. The motive which urged Demosthenes to agree to a peace is probably that assigned by Schaumann (see also Demosth. *Orat. on the Peace*), that the means of resistance were too small to allow any hope that Athens alone could use them effectually. Be that as it may, Demosthenes never slackened his efforts, and in 343 B.C. we find him accusing *Æschines* of malversation in the former embassy, and acting as one in a second to counteract Philip's influence in Ambracia and Peloponnesus. Since the cessation of the Phocian war in 346 B.C., this influence appears to have increased, as well by the weakening of Sparta and Thebes, as by his acquisition of two votes in the Amphictyonic council; hence the renewed energy of Demosthenes and the expedition of Diopeithes to the Hellespont, for the purpose of protecting the Athenian corn trade. (*Orat. on the Crown*, p. 254.)

About this time too Demosthenes became in a more decided sense the leader of his party, in the room of Chares, and for the next two years employed himself in supporting and strengthening the anti-Macedonian party in Greece. His principal measures were an embassy to the Persians; the strengthening of the alliance with Byzantium and Perinthus for the purpose of forming alliances; and the relinquishment by Athens of all claim on Eubœa, in which Phocion concurred.

The struggle now began. Philip laid siege to Perinthus, to Selymbria, and afterwards to Byzantium, and fitted out a fleet. At this juncture, Demosthenes delivered his fourth Philippic, in which, among other things, he recommended the restoration of the festival-money to its

original use, alleging the scruples felt by some concerning its application to military purposes, and the increase in revenue which rendered that application no longer necessary. In 339 B. C. the siege of Byzantium and Perinthus was raised, and a short peace ensued; but in the succeeding spring Philip was chosen Amphictyonic general. The object of Demosthenes was now somewhat changed. Before, he had to oppose a foreign influence which sought to insinuate itself into the affairs of the Grecian States; now that wish had been gained, and his business became that of arranging party against party in the different sections of the same nation.

From this time to the battle of Chæronea he was engaged in negotiations to detach different states from the Amphictyonic alliance. At Thebes he was completely successful: a strict alliance was concluded between Thebes and Athens, and Demosthenes became almost as much the minister of the one state as of the other. He defeated all the counter efforts of Python, Philip's agent, and procured the preparation of an army and fleet to act against Philip, who had seized and fortified Elatea, a principal town in Phocis. But his hopes were again destroyed at the battle of Chæronea, in the summer of 338 B. C., and Philip remained apparently master of the destinies of Greece; perhaps not unaided in the conflict by a superstition which considered his cause as in some sort identified with that of Apollo, the Delphian god. Under these circumstances, the party of Phocion made some faint attempt at action; but Philip, with his usual remarkable policy, forestalled them by releasing his Athenian prisoners and using his victory with the greatest moderation.

Demosthenes joined in the flight from Chæronea, not without some disgrace, and does not again appear till the funeral ceremony for those who fell, when he pronounced the customary oration (which, however, has been decided not to be that which goes under this name), and resumed his place at the head of the government. He became victual-provider for the city, superintended the repairs of the fortifications, and was proceeding with his usual vigour in prosecuting his political schemes, when news came that Philip had been assassinated, July, 336 B. C. The conduct of Demosthenes on this occasion, as reported by Plutarch and Æschines, has sometimes furnished a subject for strong animadversion. He is said to have appeared in a white robe, although his daughter was just dead; and he or his friends proposed honours to the memory of the assassin of Philip. As to the first of these charges, it may be said in his defence, that it only indicates how completely devoted he was to the cause of his country, even to the exclusion, in a great degree, of private affections.

Mitford has devoted a section to anecdotes of his favourite character, Philip, whose merits no admirer of Demosthenes would wish to depreciate, the chief glory of the great Athenian orator and statesman being, that he made head so successfully against such an opponent. It is the habit of party writers to ascribe unbounded virtues or to withhold all kind of praise, with equal want of reason. The history of the times of Philip and Demosthenes, by Mitford is one of the strongest examples of this habit that we can refer to.

On the accession of Alexander, Demosthenes persevered in his decided opposition to Macedon. Alexander's first employment, after his election as stateholder by the Amphictyonic league, was to quell an insurrection in the northern and western provinces of Macedonia. While he was absent, a report of his death was spread at Thebes, which revolted from the confederacy. Demosthenes (Plutarch) fanned the flame of this insurrection, and, on Alexander's sudden appearance before Thebes, Demosthenes was appointed to confer with him; but he went only to the borders of Attica. As Alexander demanded his person immediately after the destruction of Thebes, together with nine other Athenians, on the pretext of trying them as traitors, it is most probable that, when he was sent on the mission to Thebes, he had reason to fear some act of violence if he put himself in the power of Macedon. Demades, a man as high in point of intellect as he was debased in morals, was the negotiator in his place, and by some means or other contrived to save Demosthenes. If, as Plutarch relates (*Life of Phocion*), a bribe was given to Demades to persuade him to exertion in behalf of Demosthenes, it only reflects shame on the receiver, and does

not seem to implicate Demosthenes in any such charge of meanness as Mitford has made against him. (xliv., § 3.)

During Alexander's Persian expedition, Demosthenes had to sustain an attack from his old rival Æschines. He defended himself from the charges brought against him [ÆSCHINES] in the oration called that 'On the Crown.' But we hear little of him as a public man. He probably considered that, at a time when the chief enemy of the liberties of Greece was employed in schemes most likely to conduce to her welfare, from the ruinous effect they promised to produce on the strength of Macedonia, any measures likely to recall Alexander from Asia would only be the means of binding still faster those chains which it had been his own constant aim to loosen.

The only affair of moment in which Demosthenes was at this time engaged was occasioned by the treachery of Harpalus, one of Alexander's generals, who had been left governor of Babylon when Alexander proceeded on his Indian expedition. Harpalus, having grossly abused his trust, fled to Europe on the return of Alexander, accompanied by 6000 Greek soldiers. He came to Athens as a suppliant, and engaged the orators to support him. All but Demosthenes espoused his cause with readiness, and he at last concurred, not without suspicion of bribery. (Plutarch.) The Athenians, however, refused to listen to his proposal of organizing a movement against Alexander, and prosecuted Demosthenes for recommending measures not for the good of the state. He was fined 50 talents by the Areopagus, and, being unable or unwilling to pay this sum, retired to Ægina and Trœzene, where he remained from 324 B. C. till the death of Alexander, which occurred in the following year. Immediately on the news of that event, he renewed his opposition to Macedon, even before his recall, which Plutarch says was owing to this conduct.

During the Lamian war he presided at Athens, and when Antipater defeated the confederate Greeks, and marched upon the city, Demosthenes, as the prime mover of the confederacy, judged it prudent to withdraw to Calauria, a little island opposite Trœzene, where he took refuge in a temple of Poseidon. Macedonian messengers were sent to persuade him to accompany them to Antipater, but he resisted all their entreaties. Plutarch, from whom this account is taken, says, that he retired into the inner part of the temple under pretence of writing a letter, and while there took poison, and died before he could get out of the temple. Another and much more probable account, which Plutarch also gives as coming from one of Demosthenes' friends, is, that 'by the singular favour and providence of the gods he was thus rescued from the barbarous cruelty of the Macedonians;' in other words, that he died of some sudden attack brought on by the anxiety and disappointments of the last few weeks of his life.

Demosthenes seems to have been actuated all through his political life by the strongest passion to promote the interests of his native state; and if he only delayed the fate of his country, he did what no one else seems to have attempted. It is the highest praise of his prudence and foresight that all his political predictions were verified; as he distinctly foresaw, it was the influence of Macedon, and not internal dissension, which destroyed the sovereign and independent political communities of Greece. Those who expect to find in his style of oratory the fervid and impassioned language of a man carried away by his feelings to the prejudice of his judgment, will be disappointed. He is said not to have been a ready speaker, and to have required preparation. All his orations bear the marks of an effort to convince the understanding rather than to work on the passions of his hearers. And this is the highest praise. Men may be *persuaded* by splendid imagery, well-chosen words, and appeals to their passions; but to *convince* by a calm and clear address, when the speaker has no unfair advantages of person or of manner, and calls to his aid none of the tricks of rhetoric,—this is what Cicero calls the oratory of Demosthenes, the ideal model of true eloquence. (*Orat.* c. 7.) Most of the speeches of Demosthenes on political affairs, as we now possess them, are laboured compositions, which have evidently been frequently corrected by the author before he brought them into that state in which they now appear. Notwithstanding the easy flow of the language, the art and industry of the orator are visible in almost every line; and in nothing are they more apparent than in the admirable skill by which he makes

almost every period produce its effect, and in the well-judged antithesis which gives such force and precision to his expression, that it seems as if no other words and no other order of words could be so appropriate as those which he has chosen. The style of many of the orations on civil matters which were delivered before the courts of justice is very different: there is an air of easy negligence about them, and an absence of that laboured accuracy which characterizes his other compositions. It is not unusual to find sentences that might be called grammatically incorrect. But these orations are invaluable as specimens of what we now call stating a case, and well worth the attentive study of those who would make themselves acquainted with the social condition of Athens at that time.

The orations of Demosthenes may be divided into two great classes, political and judicial, and this last again into those delivered in public and those in private causes.*

Those of the first class which are extant were delivered in the following order:—The oration on the Symmoriæ, B.C. 354; for the Megalopolitans, B.C. 353; the 1st Philippic, B.C. 352; for the Rhodians, B.C. 351; the three Olynthiacs, also called the 2nd, 3rd, and 4th Philippics, B.C. 349; the 5th Philippic (which forms part of the 1st in our present copies), B.C. 347; the 6th Philippic, also called the oration on the Peace, B.C. 346; the 7th Philippic, B.C. 344; the 8th Philippic, also called the oration concerning Halonnesus, B.C. 343; the 9th Philippic, also called the oration on the Chersonesus, the 10th and 11th Philippics (also called the 3rd and 4th), all in B.C. 341; the 12th Philippic, also called the oration against the Letter, B.C. 339; the Funeral oration, B.C. 338; and the oration on the treaty with Alexander, after B.C. 334. Of these, that concerning Halonnesus, the 11th Philippic, also called the 4th, and that against the Letter, are decided to be of doubtful authority, as is also the oration on the Contribution (*περὶ συντάξεως*), which is of doubtful date, that on the treaty with Alexander, and the Funeral oration.

Of the 1st division in the 2nd class, we find those against Androtion and Leptines, B.C. 355; that against Timocrates, B.C. 353; that against Aristocrates, B.C. 352; that against Midias, B.C. 348; that on Malversation in the Embassy, B.C. 343; that against Neæra, about B.C. 340; that against Theocrines, after B.C. 336; the two against Aristogiton, after B.C. 338; that on the Crown, B.C. 330. Those who are curious respecting the date of the last-mentioned orations, may refer to Clinton (*Fasti Hellen.*, p. 361), from whom these dates are taken.

Of the 2nd division are the three against Aphobus, the two against Onetor, and that against Callippus, all in B.C. 364; those against Polycles, and on the Naval Crown, after B.C. 361; that against Timotheus, before B.C. 351; that against Euergus and Mnesibulus, after B.C. 356; that against Zenothemis, after B.C. 355; those against Bæotus and for Phormio, B.C. 350; the two against Stephanus, before 343 B.C.; that against Bæotus about the dowry B.C. 347; that against Pantænetus, after 347 B.C.; that against Eubulides, after 346 B.C.; that against Conon, after 343 B.C.; that against Olympiodorus, after 343 B.C.; that in the cause of Phormio, after 336 B.C.; that against Dionysodorus, after 331 B.C. To these must be added, that against Apaturius; that in the cause of Lacritus; that against Nausimachus and Xenopithes; those against Spudias, Phænippus, Macartatus, Leochares, Nicostratus, and Calicles. Of these in the second class doubts are entertained regarding the authenticity of those against Neæra, Theocrines, Aristogiton, Onetor, Timotheus, Euergus and Mnesibulus, Stephanus, Eubulides, Phænippus and Nicostratus; but of these Schaumann decides for those against Timotheus and Eubulides.

The orations of Demosthenes were edited ten times in the sixteenth century, and twice in the seventeenth. They have been re-edited by Taylor, Reiske, the Abbé Auger, Schaefer, and Bekker. The text of Bekker, which is now the standard, is founded on a careful collation of the MSS. Those who are admirers of the greatest orator of antiquity, and of the greatest of all ages, ought to feel under obligations to this distinguished philologist for purging the text from the wild conjectures of Reiske and others, and giving us the genuine readings of the best MSS. Of separate orations, F. A. Wolf has given an edition of that against Leptines; Rüdiger of that on the Peace, of the first Philippic,

and the three Olynthiacs; Buttmann and Blume of the Midias; and Voemel of the Philippics.

The orations of Demosthenes and Æschines were translated into German with notes, by J. J. Reiske, Lemgo, 1764; a correct, but tasteless version. The political speeches were translated with notes, by Fr. Jacobs, Leipzig, 1805-8; and the eleven Philippics, by Alb. Gerh. Becker, Halle, 1824-26. There are also other German translations of some of the speeches. There is a French translation of Demosthenes and Æschines by Auger. Leland has translated into English all the orations which refer to Philip, including the Philippics and Olynthiacs, with the oration of Æschines against Ctesiphon, and one by Dinarchus, but with no great success. To express the simplicity, perspicuity, and force of the original, would require the translator to possess powers the same in kind as those which Demosthenes himself possessed, and near them in degree.

(Mitford's *Greece*; Schaumann's *Prolegomena to Demosthenes*; Plutarch's *Demosthenes*; *Life* by Zosimus of Ascalon; *Lives of the Ten Orators*; Taylor's *Life of Demosthenes*; Clinton's *Fasti Hellenici*, and the *Orations of Demosthenes*.)

Bust of Demosthenes, Townley Gallery, British Museum.
Height, 1 foot 8½ inches.

DEMOUSTIER, CHARLES ALBERT, a French writer, born at Villers-Cotterets in the year 1760. He was connected on his father's side with the family of Racine. The work which chiefly brought him into notice was his '*Lettres à Emilie sur la Mythologie*.' These letters are written in a pleasing style, and attained that popularity which is usually awarded to works on learned subjects, when written in an amusing manner. Indeed it appears to have gained more than its just meed of applause, and the consequence was, that when this had subsided, a re-action took place, and the work was censured with too much severity. His other works are chiefly theatrical; of these '*Le Conciliateur*,' a comedy in verse, was one of the best and most successful; there is not much humour in it, and scarcely any delineation of character, but the plot is excellently constructed, the incidents are striking and uncommon, and the author has acquitted himself well of the difficult task of expressing moral sentiments, without being mawkish. An anecdote is told of Demoustier which proves his excessive good humour: A young man being present at the representation of one of the author's comedies, felt by no means satisfied, and requested the gentleman beside him to lend him a hollow key (whistling with a key being the French mode of expressing disapprobation); the gentleman complied with his request, and was no other than Demoustier himself. He died at the place of his birth in 1801.

DEMULCENTS are medicinal agents which have the property of protecting sensible surfaces from the action of irritating matter, by hindering it from coming in direct contact with them. They are thus distinguished from diluents, of which water may be taken as an example, which often lessen acrimony by diluting or attenuating the fluid in which it exists. When much water is present in any demulcent liquid, the action is partly that of a diluent, but the chief benefit results from the bland nature of the substance, or from its viscosity. Demulcents are either solutions, such as mucilage of gum arabic, or certain sub-

* The distinction between public and private causes is roughly that which in English law exists between criminal and civil cases.

stances mechanically diffused through water or milk, such as wax, spermaceti, or suet. Their beneficial effects are greatest over the mucous surfaces with which they come into immediate contact, such as the throat, stomach, and intestinal canal, but by sympathy their soothing action would appear to be extended to the mucous surfaces of the lungs, and of the urino-genital organs. Mucilaginous substances, such as gum, are not easily digested, unless some bitter or astringent principle be taken along with them; so that demulcents pass along the intestinal canal, shielding it from irritating substances throughout its entire length, though less effectually as they proceed, and become mingled with the various secretions in their passage. They thus afford considerable protection to the inner coat of the stomach and intestinal canal against poisonous agents, and for this purpose, milk, gruel, or oil, are frequently employed, though devoid of any power to disarm the substance chemically of its virulence.

DEMURRAGE, the term used in commerce to denote the money payable to the owner of a ship on the part of the shippers or consignees of goods, as compensation for detention beyond the time stipulated for her loading or discharge, as the same is expressed in the charter-party or bills of lading. It is usual to insert in all charter-parties the number of working days allowed for the loading of the ship, and also for her unloading, and likewise the sum *per diem* which may be claimed for delay beyond those periods in either case, in addition to the stipulated freight. Sometimes the number of working days for loading and unloading are stated together, so that any delay in the one case may be compensated by greater speed in the other. When the owners of the ship enter her outwards for any port, to receive such goods as may offer, and consequently where no charter-party exists, there is no stipulation for demurrage in the part of loading, but in this case it is common to insert on the face of the bill of lading a statement of the number of days after her arrival at her destined port in which time the goods must be taken from on board the ship, and also the rate of demurrage chargeable daily for any exceeding that time. No claim for demurrage can be set up where a ship is detained by contrary winds or stress of weather, nor where the government interferes to lay an embargo, nor where the port is blockaded by a hostile force, but the claim on the part of the ship ceases so soon as the goods are shipped and the clearances are passed at the Custom-house.

DEMURRER (*demorari*, to stay) is that pleading by which a question of law is raised between the parties to a suit; the party demurring refuses to proceed with the pleadings towards an issue, and requires the judgment of the court whether, upon his opponent's own showing, sufficient statement has been made to sustain the suit. A demurrer therefore admits the truth of the opponent's allegations. (Stephen; Co. Litt.)

DEMUS. [ATTICA.]

DENARIUS, a Roman coin of silver, so called from containing ten asses. It answered to the Attic drachma. After the first Punic war, the denarius became the representative of sixteen asses, and though Augustus reduced it to twelve, it continued subsequently at the value of sixteen as low as the time of Gallienus. Pinkerton says it was worth eight-pence of our money. It was the chief silver coin in Rome for 600 years, down to the time of Constantine I.

The earliest denarii are those which have the helmeted head of Rome, the Dioscuri, or the head of Jupiter, upon their obverse. Many of them had chariots, bigæ, or quadrigæ, represented on their reverses; such coins were called *bigati* and *quadrigati*. The half of the denarius was called *quinarius*, as containing five asses; the quarter, *sestertius* as money *semistertius*, containing two asses and a half.

Many of the family Denarii, as those of the Ælian, Æmilian, Calpurnian, Didian, Fulvian, Papinian, Tullian, and numerous other families, were marked on the obverse with the numeral x; others of the same and other family coins have the x crossed by an upright or horizontal bar, sometimes taken for a star or asterisk, but clearly intended to designate the value. The denarii which went for sixteen asses sometimes continued to be marked with x, and sometimes had the numerals xvi. Akerman, in his *Descriptive Catalogue of rare and unedited Roman Coins*, 8vo., Lond., 1834, vol. i., p. 15-19, has given the actual weight of the silver denarii in Troy grains, from Pompeius Magnus to Constantinus Magnus.

The *denarii æris* or *ærei*, of copper, began with the Emperor Valerian, and were at first washed with silver. Pinkerton thinks they came in the place of the sestertius, and that six of them went to the silver denarius, as six of the later sestertii did.

The word denarius was also applied to the ordinary gold coin of Rome, the *aureus*, in the same manner as the English writers speak of the gold penny of Henry III. *Aurei denarii* are mentioned by Petronius. The denarius aureus was equivalent to 30 silver denarii. The half-aureus, in the same manner, was termed *quinarius*. (Morelli *Thesaur. Famil. Roman.*; Greave's *Disc. of the Roman Foot and Denarius*, 8vo. Lond., 1647; Pitisci *Lexicon Antiq. Gr. et Rom.*, tom. i., pp. 646, 647; Rasche's *Lexicon Universæ Rei Numariæ*, vol. ii., p. i., p. 138; Pinkerton's *Essay on Medals*, vol. i.)

Roman Denarii.

British Museum. Actual Size. Silver. Weight 60.6 grains.

British Museum. Actual Size. Silver. Weight 58.6 grains.

DENBIGH. [DENBIGHSHIRE.]

DENBIGHSHIRE, a county of North Wales, of very irregular form. It is bounded on the north by the Irish Sea; on the north-east by the county of Flint; on the east by that of Chester, from which it is separated by the Dee; on the south-east by a detached part of Flintshire, and by Shropshire, from both which it is also separated by the Dee; on the south by Montgomeryshire; on the south-west by Merionethshire; and on the west by Caernarvonshire, from which it is separated by the river Conwy. A small detached part of the county is included between Salop and Montgomeryshire. Its greatest length is from north-west (Llan Drillo Rhôs, near Little Orme's Head) to south-east, (Llan Gedwyn, on the river Tanat), 41 miles; its greatest breadth from the extremity of the county near Eaton Hall (which is in Cheshire), to the source of the Rhaiadr, which flows into the Tanat, about 29 miles. The area of the county is about 633 square miles, and the population in 1831 was 83,629, giving 132 persons to a square mile. Denbigh, the county town, is on a stream which flows into the Clwyd: it is about 180 miles from London, in a direct line north-west; 203 miles by the road through Birmingham, Walsall, Newport, Whitchurch, Wrexham, and from thence to Denbigh, either by Ruthin or Mold; 205 miles by the parliamentary Holyhead road to Llan Gollen, and from thence by Ruthin to Denbigh; or 209 miles by Shrewsbury, Ellesmere, Wrexham, and Mold.

Surface, Hydrography, and Communications.—The Hiraethog hills, which occupy the western side of the county towards Caernarvonshire, extend from the north-western extremity of Denbighshire, near Little Orme's Head, in a SSE. direction, skirting the valley of the Conwy, to which they present their steepest side; on the east side several ridges of hills varying in length from five to nine or ten miles, run out laterally from the principal range. The Hiraethog hills, with these lateral branches, form one of the most extensive and dreary wastes in the principality of Wales, stretching in length from 25 to 30 miles, from the neighbourhood of Little Orme's head to near the town of Corwen (Merionethshire), on the Dee; and in breadth, according to the extent of the lateral ridges. The general covering of these hills is heath or ling: the hollows and flats abound with excellent peat for fuel, which is so close-grained as to exhibit a polished surface when dry and cut with a sharp-edged tool. The principal summits of the Hiraethog range, in the order in which they occur, from NNW. to SSE., are, Llan Elian mountain, 1110 feet; Moel*

* Moel' signifies bald, crop-eared, or wanting horns: it is applied to a lofty hill bare of wood.

Cranaw, Modwl Eithin (the highest point of the range), 1660 feet; Cader Danad, and Cader Ddimel. In a branch ridge which runs from the neighbourhood of Eglws Fâch, near the Conwy, to the neighbourhood of St. Asaph, are Moel Fre Ucha,* 1234 feet, Moel Fre Issa,* 1037 feet, and Bryn-y-pin. In other branch ridges there are Moel Fodian, or Fodiar, 1260 feet, and Moel Tywysog, or Twysog, 1260 feet, both to the west of Denbigh; Bronhaulog, north-west of Ruthin, and Bronbanog, near the source of the Clwyd, 1572 feet. The eastern side of the county, adjacent to Flintshire, is occupied by part of two parallel ranges of hills, (the western range called the Clwydian hills), which commence on the coast of Flintshire, and entering Denbighshire, run southward more than 20 miles, towards the valley of the Dee, and are united by the hills, which form the northern side of that valley to the Hiraethog range already described. The whole may be considered as forming one range 60 to 65 miles long, in the form of a horse-shoe, or of the letter U, and enclosing the beautiful and fertile vale of Clwyd. The Clwydian hills and the parallel range inclose a valley watered by the river Allen (Alen or Alyn), a tributary of the Dee. The principal summits of the Clwydian range in their order from NNW. to SSE., are Craig† Arthur, Moel Arthur, 1491 feet; Moel Fammau, or Vammau, 1845 feet, and Moel Ciw. Craig Brain or Cyn Brain, in the range parallel to and east of the Clwydian hills, is 1858 feet; and Moel Enlli, or Venlli, in a small ridge, also parallel to the Clwydian hills, and nearer to the river Clwyd, is 1767 feet. In the hills north of the valley of the Dee there is Moel Morfidd, 1767 feet. The Berwyn hills, which separate the basin of the Dee from that of its tributary, the Ceiriog, and the hills which separate the basin of the Ceiriog from that of the Tanat (whose waters flow, though not immediately, into the Severn,) occupy the southern part of the county. Cefn Ucha, in the Berwyn range south of the town of Llan Gollen, is 1316 feet high.

The waters of Denbighshire find an outlet into the sea chiefly by the Conwy, the Clwyd, and the Dee, not one of which has its æstuary within the county. The Conwy carries off the waters of the western slope of the Hiraethog hills: the Clwyd drains the country inclosed between the Hiraethog and the Clwydian hills, except a small part which is drained by the Alwen, a feeder of the Dee; the Dee receives by several tributaries the waters of the rest of the county. The Conwy is noticed under CAERNARVONSHIRE. Its Denbighshire tributaries are all small, for the hills on whose slopes they rise are near the main stream: these tributaries, following the order in which they join the Conwy, are the Serw, which flows from Llyn Serw and joins the Conwy near its source, the Clettwr, the stream from Cynrioge (which is perhaps the largest of these affluents, though not more than six or eight miles long), the Afon Hwch, the stream which passes Eglwys Fâch, and many other smaller streams.

The Clwyd rises near the hill Bronbanog. [CLWYD.] The width of the valley of the Clwyd allows the formation of several large affluents.

The Dee touches the border of the county four or five miles below the town of Corwen (Merionethshire), and after separating it from Merionethshire for a mile or two, quits the border and crosses Denbighshire in a winding course from west to east through the vale of Llan Gollen, passing the town of Llan Gollen and Wynnstay, the seat of Sir W. W. Wynn. A little below Wynnstay it reaches the border of the county, and turning first north-east, and then north, divides it from Shropshire, a detached part of Flintshire, and Cheshire, until it finally quits Denbighshire a little above Eaton Hall. That part of the course of the Dee which is upon or within the border of the county, may be estimated at more than forty miles; the river is not navigable till after it leaves Denbighshire. Of those feeders of the Dee which belong to Denbighshire, the Rhaiadr or Moch, the Alwen, the Ceiriog, the river which rises at Minera and passes near Wrexham, and the Alen, or Alyn, are the chief. [DEE.]

The Rhaiadr, or Moch, is a small stream which forms the boundary of Denbighshire and Merionethshire. Its length does not exceed seven or eight miles, but forms in its course the celebrated waterfall of Pistill Rhaiadr. 'It terminates,' says Mr. Pennant, whose account we copy, 'the precipitous end of a very narrow valley, and divides a bold front of

the Berwyn mountains. After sliding for some time along a small declivity, it darts down at once two-thirds of the precipice, and falling on a ledge, has, in process of time, worn itself a passage through the rock, and makes a second cataract beneath a noble arch which it has formed, on the slippery summit of which a daring shepherd will sometimes terrify you with standing. The second fall reaches the bottom, and assumes the name of Rhaiadr, or the cascade. The defect of this noble fall is the want of wood.' (*Tour in Wales*, London, 1784, 2 vols. 4to., vol. ii., p. 363.) Mr. Pennant does not give the height of the fall, but in the 'Beauties of England and Wales' it is described as being in all about 200 feet.

The southern border of the county is skirted for about five miles by the Tanat, which flows by the Vyrnwy into the Severn. The Ywreh, the Cwmrhiw, and one or two other affluents of the Tanat, belong to Denbighshire, but they are small. Some small streams in the northern part of the county flow directly into the sea between the Conwy and the Clwyd. The Dolwen, the largest of these, has a course of not more than seven or eight miles.

There is in Denbighshire a navigable feeder of the Ellesmere Canal. It is taken from the Dee near Llan Tysilio, in this county, and follows the valley of that river to the neighbourhood of Ruabon (or Rhiw Abon), where there is a short railroad from the canal to Ruabon brook. The canal then turns abruptly, and crossing the river Dee, over which it is carried by the aqueduct bridge of Pont Cysylltee, runs southward to the river Ceiriog, over which it is carried by another aqueduct bridge, and thence into Shropshire. The aqueduct bridge of Pont Cysylltee is a stupendous work: it is supported by nineteen pairs of stone pillars fifty-two feet asunder, and is carried over the river at the height of 125 feet above its bed. The trough through which the vessels pass is entirely composed of cast iron plates, and is 320 feet long, 20 feet wide, and 6 feet deep. There is another large aqueduct bridge over the Ceiriog, built of stone, which is 600 feet in length, and is supported on ten arches at an elevation of sixty-five feet above the river.

Of the roads which cross Denbighshire the most important is the parliamentary mail road from London to Holyhead, the principal channel of communication between the Metropolis and Ireland. It enters Denbighshire near the village of Chirk, and runs northward to near the Dee, where it turns to the west, and passing through Llan Gollen, enters Merionethshire. It afterwards re-enters Denbighshire, which it finally quits by crossing the Conwy at Bettws y Coed. This part of the road has been much improved under the direction of the parliamentary commissioners, by avoiding steep and dangerous hills, and making a direct and commodious passage, by which the necessity of passing through the narrow and crooked streets of Llan Gollen has been avoided. The mail road from London to Holyhead, by Chester, passes through the northern part of this county near the coast: it enters it between St. Asaph and Abergely or Abergelau, and quits it at the bank of the Conwy. Denbigh, the county town, is the centre from which several principal roads run. (*Physical and Political Geography of the British Islands*, in the *Library of Useful Knowledge*; *Davies's General View of the Agriculture, &c. of North Wales*; *Paterson's Roads*, by Mogg; *Priestley's Account of Rivers, Canals, &c., in Great Britain*; *Arrow-smith's large Map of England and Wales*.)

Geological character.—In describing the geological character of this county, we shall notice the principal rocks which are found in it in the order of superposition, beginning with the uppermost, the red marle or new red sandstone. This rock occupies part of the coast on the north side of the county, and skirts the Clwyd from its mouth to above Ruthin. It is found also occupying a considerable tract in the eastern part of the county, along the Dee, extending from that river to the town of Wrexham; and again it is found in the valley of the Ceiriog, near the village of Chirk. The coal-measures which underlie the red marle, and which form the coal-field of Flintshire, extend from that country into Denbighshire as far as Wrexham, and again appear in the valley of the Dee, extending from Ruabon to Chirk. Coal is dug both near Wrexham and in the neighbourhood of Ruabon. Common, cannel, and peacock coal are found in these coal-measures. The coal-measures rest on a base of shale and sandstone, answering in position and character to the millstone grit of Derby-

* 'Ucha,' upper; 'Issa,' lower.

† Craig, i. e. Crag, rock.

shire: this base rises to the surface, and occupies a narrow strip of the country extending from Flintshire south-east to Wrexham, and from that town south by west to Chirk; after which it continues into Shropshire, skirting the Flintshire and Ruabon coal-fields. The shale is succeeded by carboniferous limestone or mountain limestone, which extends from the coast, in the neighbourhood of Great and Little Orme's Head (both these promontories consist of this rock), and forms part of the mass of the hills that extend from the Hiraethog hills to the vale of Clwyd. A considerable part of that vale, and the upper part of the valley of the Alen, separated from it by the Clwydian hills, are also occupied by this limestone, which extends south-east from the vale of Clwyd across the vale of Llan Gollen into Shropshire. The older red sandstone, which underlies the mountain limestone, occupies a narrow belt of the surface, skirting the district which has just been described as occupied by the limestone. The Hiraethog hills are formed principally of transition limestone. The rest of the county is occupied by the clay slates and greywacké slates, which are so abundant in Wales. (Conybeare and Phillips's *Outlines of the Geology of England and Wales*; Greenough's *Geological Map of England and Wales*; Walker's *do.*)

The coal-mines of Wrexham and Ruabon have been already mentioned. There are some old lead-mines near Abergely, on the coast: others in the range of limestone hills which run parallel to the Clwydian Hills on the east, and others again in the neighbourhood of Ruabon. Iron ore is dug at Ruabon and in the neighbourhood of Wrexham. Slate is quarried near Chirk; millstones are procured in the hills which bound the valley of the Ceiriog, and freestone for building in various places, especially near the coal-field.

Divisions, Towns, &c.—Denbighshire, as well as the neighbouring county of Flint, appears to have been comprehended in Y. Perfeddwlad (*i. e.* the middle or inland country), one of the four divisions into which Gwynedd or North Wales was divided. This district of Y. Perfeddwlad contained five cantrefs or larger divisions, which again were subdivided into cwmwds or smaller divisions, as follows:—

Cantrefs	I., Rhyfonioc.	Cwmwds	i., Uwchaled.
"	"	"	ii., Isaled.
"	II., Ystrad	"	iii., Hiraethoc.
"	"	"	iv., Cynmeirch.
"	III., Rhôs	"	v., Uwchdulas.
"	"	"	vi., Isdulas.
"	"	"	vii., Creuddyn.
		(This cwmwd is included in the present Caernarvonshire.)	
"	IV., Dyffryn Clwyd	"	viii., Coleigionn.
"	"	"	ix., Llannarch.
"	"	"	x., Dogfeilyn.
"	V., Teygengle	"	xi., Cynsyllt.
	(This last cantref forms part of the present county of Flint.)		
"	"	"	xii., Prestatyn.
"	"	"	xiii., Rhuddlan.

These districts and subdivisions have been superseded by the modern counties and hundreds, which divisions were introduced as late as the reign of Henry VIII. From the time of its coming into the hands of the English until the reign of that monarch, Denbighland was comprised in districts, governed by their own antient laws and usages, and exempt from the laws of England, because all the ordinary administrators of the English laws were the officers of particular counties. By statute however in the 27th year of Henry's reign, four new shires were formed in Wales, of which Denbigh was one: these were subdivided into hundreds; and it was enacted that the English laws should from thenceforth be in force through Wales, all laws, customs, and tenures, inconsistent therewith being for ever abolished. Denbighshire is included in the North Wales circuit.

The present hundreds are six, *viz.*—Bromfield, comprehending the country between the Dee and the Allyn, and including the towns of Wrexham and Holt; Chirk, comprehending all that part of the country south of the Dee;

Isaled, comprehending the south-west part and extending into the centre; Isdulas, extending along the north coast and along the lower part of the valley of the Conwy; Ruthen, comprehending the north-east parts and extending into the centre; and Yale, occupying a narrow strip between the hundreds of Ruthen and Bromfield, and between Ruthin hundred and the county of Flint. The county contains one principal borough and market-town, *viz.*, Denbigh: two market-towns, which are contributory boroughs to Denbigh, *viz.*, Wrexham and Ruthen; one borough which has no market, Holt; and two market-towns, Llan Gollen and Llan Rwsst.

Denbigh, from which the county takes its name, is situated near a stream which flows into the Clwyd. Its situation on a rocky eminence, the summit of which is crowned by the ruins of the antient castle, gives it a striking appearance. It consists chiefly of one long street, well-paved and lighted, with a few good houses, leading into a spacious market-place. The market-house and assembly-room are in the market-place. The castle is said to have been erected by Henry Lacy, earl of Lincoln, upon whom Edward I. conferred the lordship of this place upon the overthrow of David, the brother of the last prince of Wales, Llewelyn. The castle walls were of peculiar structure and extraordinary strength: the outer and inner faces were built in the usual way, and the interval was filled with rough stones of all sizes and with a grouting of hot mortar, which, on cooling, formed a mass as hard as stone. The castle was never quite finished: it is said that Earl Lacy's son got his death by falling into the castle well, and that the earl being called away on military service, never afterwards came to finish the structure. In Leland's time it was a large fortress with many towers, wards, and portcullises: over the gate was an effigy of the founder. The grand entrance to the castle, a magnificent pointed archway, with the statue of the founder in a niche over it, in tolerably good preservation, still remains: it was formerly flanked by two large octagonal towers, one of which is nearly demolished, and the other is in a very ruinous state. Earl Lacy is said by some to have walled in a village which previously existed here: by others it has been doubted whether there were any habitations on the hill before he made this inclosure, which was not exactly on the site of the modern town, but higher up the castle hill. The walls, which run round the brow of the hill, inclose a considerable area, partly used for pasture, partly as a bowling-green, and partly occupied by cottages. One of the town gates (the Burgesses Gate), defended by two towers, is tolerably perfect. The original parish church of Denbigh is at Whitechurch, nearly a mile east of the town; it is very antient, and now much dilapidated. The townspeople use as their place of worship a chapel near the castle gate, within the old town walls, once belonging to the garrison of the castle, and dedicated to St. Hilary. There was antiently a priory of the Carmelites or White Friars in the town, some remains of which yet exist.

The population of the borough of Denbigh, which extends far beyond the town, and includes most of the village of Henllan, nearly two miles off, was in 1831, 3786. There are some tanneries, and many shoes are made, which are sent to Liverpool and to the surrounding fairs and markets; but Denbigh is less a place of business than of genteel retirement. The markets are on Wednesday and Saturday, and there are five fairs in the year. There are several dissenting places of worship; two schools partly endowed, two national schools, and one other day school; two boarding schools for girls, four infant schools, and four Sunday schools: the Sunday schools contain in all 1780 children. (*Educ. Returns* for 1833.)

The borough council under the Municipal Reform Act consists of four aldermen and twelve councillors. A mayor is chosen yearly from among the aldermen or councillors. Denbigh, with its contributory boroughs, Ruthen, Holt, and Wrexham, returns one member to parliament. The number of 10 $\frac{1}{2}$ houses within the borough (the boundaries of which were not altered in the Boundary Act) was, in 1831, 260, of which 96 had land attached. Denbigh is the chief place of election, and one of the polling stations for the county. The Epiphany and Trinity quarter sessions are held here the other sessions and the assizes, at Ruthen. The living is a rectory in the diocese of St. Asaph, of the annual value of 445 $\frac{1}{2}$ l., in the archdeaconry and diocese of St. Asaph. It is in the patronage of the bishop of St. Asaph.

Denbigh was burnt during the war of the Roses by a body of Welshmen under Jasper Tudor, earl of Pembroke, half brother of Henry VI. In the civil war of the seventeenth century Charles I. took refuge here for a short time. The castle was taken by the parliamentary forces under General Mytton, A.D. 1646.

Wrexham is in the hundred of Bromfield, upon a small stream that flows into the Dee, a few miles from the west or left bank of that river, and upon a road leading from London by Birmingham, Walsall, and Whitechurch, to Holyhead. It is 179 miles from London by this road, and about 12 miles S.S.W. of Chester.

Wrexham is advantageously situated in the mining district of Denbighshire, and is one of the most important towns in North Wales. The houses are in general well-built; the streets, which are wide and generally cross each other at right-angles, are paved and lighted with gas. The church is a handsome and spacious Gothic building: it consists of a nave, two aisles, and a chancel, and is adorned with many tombs, and an abundance of grotesque carving, 'in ridicule,' according to Pennant, 'of the regular clergy, and the female religious, abbesses and nuns.' On the outside of the church is a quantity of ludicrous and gross sculpture. The tower of the church has an elevation of 135 feet, and has on three sides rows of saints in richly sculptured niches. The church was built in the room of a previous one destroyed by fire in the fifteenth century; the tower was not finished until early in the sixteenth. The town-hall is a plain brick building: there are a county house of correction, and places of worship for various classes of dissenters. There are several gentlemen's seats in the vicinity.

The town is not the seat of any particular trade or manufacture; but in the parish, which is very extensive, there are quarries, lead-mines, and collieries. The iron works have been long neglected. There are two weekly markets, on Monday and Thursday, and several annual fairs. One fair, held in March, lasts many days, and is one of the most important in North Wales: cattle and horses, Welsh flannels and other woollens, Irish linens, Manchester cotton goods, Yorkshire woollens, and hardwares from Birmingham and Sheffield, are sold at this fair. The parish, which extends into Flintshire, is subdivided into fifteen townships, and contained, in 1831, 11,521 inhabitants. The town is in the townships of Wrexham Abbots and Wrexham Regis (which contain a population of 5484), and in a small part of the township of Esclusam below. By the Reform Act, Wrexham was made a contributory borough to Denbigh. The parliamentary borough comprehends the townships in which the town stands: within the limits, there were at the time of the Boundary Commissioners' Reports, about three hundred and thirty-one 10^l. houses. Wrexham is one of the polling places for the county, and the petty sessions for the hundreds of Bromfield and Yale are held here. There is a small theatre occasionally opened for dramatic performances, and there are races every year.

The living is a vicarage in the archdeaconry and diocese of St. Asaph, of the annual value of 746^l.: it is in the gift of the bishop of St. Asaph.

From the education returns, it appears that there were in the parish in 1833 two infant schools, with 131 children; thirty day or boarding and day schools, with 1000 to 1100 children; and nineteen Sunday schools, with above 2000 scholars. Of the thirty day schools, six were wholly or partly supported by gift or endowment, including a grammar school, two national schools, and one on Dr. Williams's foundation.

Ruthen, Ruthin, or Rhuthyn, is eight miles from Denbigh. It is, like Denbigh, situated on the summit and slope of a considerable hill, at the foot of which flows the Clwyd. The town appears to have taken rise from the foundation of the castle, which was built by Roger Grey, to whom Edward I. granted nearly the whole of the vale of Clwyd. This castle got the name of Rhyddin, or the Red Fortress, from the colour of the stone of which it was built. It stood, not on the summit, but on the western slope of the hill, towards the Clwyd. It was so much neglected, that by the time of Henry VIII. it had become roofless, and was falling fast to decay. It appears to have been subsequently repaired, and was garrisoned for King Charles I. during the great civil war; but having been taken by the parliamentary troops under General Mytton, it was ordered to be dismantled. It appears to have been capacious and lofty. A new edifice, which from its style may be con-

sidered as a restoration of the antient castle, has been erected on the site, and is now the seat of Mr. West. The summit of the hill is occupied by the market-place, to which the principal streets lead. The county-hall or court-house is the finest building for the purpose in North Wales. The county prison is well built. The church is part (the choir) of a more spacious building, was originally the conventual church of a community of Bonhommes (suppressed A.D. 1310), and afterwards rendered collegiate. There are vestiges of the walls of the nave and a transept. The roof of the present church is admired for its curious workmanship. Part of the cloisters have been converted into a residence for the warden of Christ's Hospital: the groined arches of the entrance and of the two parlours are much admired. The free-school is a good building.

The parish of Ruthen, which is small, contained, in 1831, 1381 inhabitants; but the borough boundaries extend far beyond the town, and comprehend a considerable rural district consisting of parts of the parishes of Llan Fwrog, Llan Rhydd, and Llan Ynys, and, according to the Boundary Reports, part of the parish of Llan Fair Dyffryn Clwyd, but the population returns do not notice this. The gross population of the borough in 1831 was 3376, including the inmates of the county gaol and female prison. The number of 10^l. houses was about 150. There is no particular trade or manufacture carried on in the town. There are two weekly markets: on Monday for corn, and on Saturday for butchers' meat; and five fairs in the year.

The corporation under the Municipal Reform Act consists of four aldermen and twelve councillors. One of the aldermen or councillors is annually chosen mayor. The elective franchise, before the Reform Act, was in the burgesses resident at the time of the issue of the writ. The assizes for the county are held at Ruthen: the quarter-sessions are held alternately here and at Denbigh. It is one of the polling places for the county.

Dr. Gabriel Goodman, whose monument is in the church, was a great benefactor to the town. He founded an hospital or alms-house for a warden and twelve decayed house-keepers, ten men, and two women. The warden and pensioners are impropiators of the great tithes of the parishes of Ruthen and Llan Rhydd: the warden appoints two curates to do the duty of these two parishes, but is expected occasionally to preach himself. He has the government of the free-school, which was also founded by Dr. Goodman, and endowed with a moiety of the tithes of Llan Elidan, to which parish, as well as Ruthen, it is free. It is accounted one of the best schools in North Wales. It contained, in 1833, forty-seven scholars. A lending library is attached to it. There were at that time in the town four other day schools, containing 141 children; besides a national day and Sunday school of forty boys and forty girls. There were three Sunday schools, containing nearly 400 children. There are meeting-houses for Independents, Wesleyan Methodists, and other Dissenters.

The wardenship of Christ's Hospital is in the gift of the dean and chapter of Westminster; the yearly income of the warden is 263^l., with a residence. The parishes of Ruthen and Llan Rhydd are in the diocese of Bangor, and in the peculiar jurisdiction of the bishop. There was once a house or cell of White Friars (Carmelites) here: Ruthen Mill is supposed to have been their cell.

Holt is on the river Dee, which here serves to separate Denbighshire from Cheshire, five or six miles N.E. of Wrexham. Holt took its rise from a castle founded by John, earl of Warren, who had acquired possession of the surrounding district by the murder of his ward, the son or grandson of Gryffydd ap Madog. In the civil war of Charles I. this castle was garrisoned for the king, but seized in 1643 by the Parliamentary troops. Being retaken by the Royalists, it was again besieged (Feb. 1645-6) by the Parliamentarians under Mytton, and after a gallant defence of two months obliged to surrender. There are scarcely any relics of it left, even of its foundations. The town is an irregular assemblage of streets or lanes; the main street leading down to the bridge of ten arches over the Dee, by which Holt is united to the village of Farndon. This bridge was built in 1345; there are relics of a guard-house in the middle. The chapel of Holt is a plain building in the perpendicular English style. The parish of Holt contained in 1831 a population of 1609 inhabitants; of these 1015 were in the township of Holt, which constitutes the

parliamentary borough, and comprehends a large rural district round the town. There were in it only about 38 houses of the annual value of 10*l.* or upwards. The population is chiefly engaged in agriculture. There is no market, but there are two cattle fairs in the year. The living is a perpetual curacy (a dependency upon the vicarage of Gresford), in the diocese and archdeaconry of Chester, and in the gift of the dean and chapter of Winchester. It is of the annual value of 101*l.* with a glebe-house. There is a Baptist meeting-house. There were, in 1833, a free school, and three other day schools, in one of which most of the children attended on Sunday also, and a Sunday school connected with the Baptist congregation; there was a school-house building for another Sunday and daily school.

Llan Gollen stands on the right or south bank of the river Dee, and on the parliamentary mail road from London to Holyhead, 184 miles from London. The town does not possess any particular claims to notice, but the vale of Llan Gollen is interesting from its picturesque beauty and its antiquarian remains, and is much resorted to by tourists. The streets are narrow, and the houses are built of a dark shaly stone. The bridge was built by John Trevor, bishop of St. Asaph, who died in 1357; it consists of five arches, the widest not having more than 28 feet span. The river usually runs under only one arch, under which it has worn a deep channel in the hard rock which forms the bed of the river. The view through the arches upwards or downwards is extremely pleasing.

The extensive parish of Llan Gollen contains a population of 4498. Of these a considerable part are engaged in agriculture, and another considerable portion in stone quarries and lime works. Some manufactures are carried on in the parish, as of flannel, cotton goods, and earthenware; there are also iron works and collieries; the town derives considerable advantages from the influx of visitors. The market is on Saturday, and there are five fairs in the year. The Ellesmere canal passes through the parish. Llan Gollen is one of the polling places for the county.

The living is a vicarage in the diocese and archdeaconry of St. Asaph, of the yearly value of 350*l.* with a glebe-house. It is in the gift of the bishop of St. Asaph. There are places of worship for Independents, Baptists, Calvinistic and Wesleyan Methodists, and Wesleyan Methodist Reformers. There were in 1833, in the parish, one boarding and day school, and eight day schools; one of these was partly supported by three small endowments. In these schools, 105 boys and 112 girls (together 217) were taught; there were besides eleven Sunday schools, in which were nearly 1000 scholars.

In the neighbourhood of Llan Gollen are several interesting remains of antiquity. Castell Dinas Brân, whose remains nearly cover the summit of the conical hill on which it is placed, is on the north bank of the Dee just opposite to the town. It was a Welsh castle, built of the coarse stone of the country, with here and there a few free-stone mouldings.

Llan Egwest, or Valle Crucis Abbey, is just within the parish of Llan Tysilio, and on the border of that of Llan Gollen. It was founded by Madog ap Gryffydd Maelor, prince of Powys, for monks of the Cistercian order. It had at the suppression a yearly revenue of 214*l.* 3*s.* 5*d.* gross, or 188*l.* 8*s.* clear. There are still some beautiful remains of the church and of a part of the abbey, the latter now converted into a farm house. A short distance from the abbey is the remainder of a round pillar, called the pillar of Eliseg, probably the most antient British inscribed pillar existing.

Llan Rwt is at the border of the county, and on the east or right bank of the Conwy, and to the right of the parliamentary road from London to Holyhead, 218 miles from London. It is situated in a pleasant vale surrounded with well-wooded hills. The houses are irregularly built, and the streets, with the exception of that in which the town-hall stands, are narrow. The church has little architectural beauty, but the interior has some curious carving, said to have been brought from the neighbouring abbey of Maenan, and there is a lateral chapel, 'the Gwydir Chapel,' built in 1633, from a design by Inigo Jones; but it is sadly neglected. (Pennant.) The bridge over the Conwy is also from designs by Inigo Jones: it consists of three arches, of which the middle one has a span of 59 feet. The tide flows up to about a mile and a half from the bridge,

and in spring tides brings up boats of twelve tons. (Pennant.) The parish extends into Caernarvonshire; it contains in all a population of 3601, chiefly agricultural. There is no particular manufacture carried on; some Welsh harps were formerly and perhaps are still made here; the corn trade is considerable. The market is on Tuesday, and there are five fairs in the year. Llan Rwt is one of the polling places for the county. The living is a rectory in the diocese and archdeaconry of St. Asaph, and in the gift of the bishop of that see. The annual value is 720*l.* and there is a glebe-house. There is a chapel of ease at Llan Garmon. There were, in 1833, in the whole parish three day schools, in which above 50 children were educated, and seven Sunday schools, in which above 1000 scholars are taught. There are several dissenting places of worship, and a range of almshouses erected in 1610 by Sir John Wynne.

Maenan or Maynan Abbey near Llan Rwt was founded by King Edward I. in 1283: the Cistercian monks of an abbey at Aberconwy were transferred hither. At the dissolution, the yearly revenue of the abbey was 179*l.* 10*s.* 10*d.* gross, or 162*l.* 15*s.* clear.

Ruabon or Rhuabon (or to give the Welsh orthography, Rhiw Abon) is a village at the junction of the roads from Oswestry and Llan Gollen to Wrexham. The church is spacious, and is adorned by some elegant monuments of the Wynne family, especially one by Rysbrach, to the memory of the first Sir Watkin Williams Wynn, who died in 1747. Wynnstay, the seat of the present Sir W. W. Wynn, is at Ruabon, the entrance to the park being immediately from the village. In the parish is an antient British fortified post: the area is about four acres, and it is defended by two ramparts and two ditches; the inner rampart is a massy wall, on the top of which is a carriage drive. In the vicinity of this post, in 1161 or 62, Owain Cyfeiliog, prince of Powys, defeated the English, and commemorated his victory in a poem called *Hirlas Owain*, 'the drinking horn of Owain.' The population of the whole parish of Ruabon, which is divided into four townships, was, in 1831, 8353, of whom above 600 were employed in the collieries and iron-works: the iron ore is partly dug in the adjacent hills, and partly brought from Lancashire. The Ellesmere canal passes through the parish; and there is a railway to Ruabon brook. Although the place does not commonly rank as a market-town, a market is held every Monday. There were in the parish in 1833 four day schools (one endowed, and two partly supported by donations), affording instruction to about 200 children; and five Sunday schools, in which were about 460 or 470 scholars. There are several dissenting meeting-houses in the parish, and two sets of almshouses. There are three fairs in the year. The living of Ruabon is a vicarage in the diocese and archdeaconry of St. Asaph, of the annual value of 588*l.*, with a glebe-house: it is in the gift of the bishop of St. Asaph.

Chirk is a village near the north bank of the Ceiriog, on the road from Oswestry to Ruabon and Wrexham, about five miles south of Ruabon. A mile and a half north-west of the village is Chirk Castle, the seat of Mrs. Myddleton Biddulph, built by Roger Mortimer in the thirteenth century. It is a large oblong square, built round a quadrangular court, and inclosed by massive walls strengthened by round towers at the corners: there is a fifth tower close to the entrance. The interior is handsomely fitted up, and contains, among other apartments, a gallery 100 feet long, adorned with the portraits of many public characters of the time of Charles II. From the castle grounds, which are very extensive, it is said that seventeen counties may be seen. Chirk Castle is on the site of a former one, called 'Castell Crogen.' The population of Chirk parish in 1831 was 1598: a considerable number of men are employed in coal-pits, stone-quarries, and lime-works. There are several paper-mills in the neighbourhood. There are three fairs in the year. The Ellesmere canal runs by Chirk. There are in the parish two boarding schools and one day school, containing in all 70 to 80 children; two day and Sunday schools, supported by Mrs. Biddulph, containing from 100 to 130 children; and one Sunday school, containing 30 to 40 children, partly supported by a donation from the family of the same lady. The living of Chirk is a vicarage in the diocese and archdeaconry of St. Asaph, and in the gift of the bishop of that see: the annual value is 466*l.*, with a glebe-house.

Divisions for Ecclesiastical and Legal Purposes.—The county of Denbigh is for the most part comprehended in

the diocese and archdeaconry of St. Asaph: a small part is in the diocese and archdeaconry of Bangor, and several parishes are in the peculiar jurisdiction of the bishop of Bangor. A very small part is in the diocese and archdeaconry of Chester. The number of parishes which are partly or wholly within the county, according to the population returns for 1831, is sixty-five, of which however five, viz., St. Asaph, Bangor-Monachorum, Bôd Fary, Erbistock, and Nannerch, rather belong to Flintshire. Of the remaining sixty, ten extend into other counties, viz., Gresford or Croes Ffordd, and Wrexham, into Flintshire; Yspytty Efan, Llan Drillo Rhôs, Llan Rwt, and Eglwys Fâch, into Caernarvonshire; Llanfihangel Glyn y Myfyr, into Merionethshire; Llan Rhaiaadr yn Mochnant, into Montgomeryshire; Llan Silyn, into Shropshire; and Llan y Myneich, into Shropshire and Montgomeryshire: fifty are wholly in Denbighshire. The number of benefices is sixty-four,* being rather more than the number of parishes, for the parishes of Llan Armon yn Yale and Llan Gwm are sinecure rectories as well as vicarages; the parish of Llan Sannan is divided into two portions, one a vicarage and sinecure rectory, the other a sinecure rectory only; and the united perpetual curacies of Berse or Bersham Drelinecourt and Minera, are parts of the parish of Wrexham. Of these sixty-four benefices, twenty-nine are rectories (three of them sinecures); two rectories (one of them a sinecure) united with vicarages; eighteen vicarages; twelve perpetual curacies; one chapelry; one wardenship (Ruthen); and one donative. Classified according to their value, there are six the yearly income of which is under 100*l.*, sixteen under 200*l.*, thirteen under 300*l.*, seventeen under 500*l.*, and seven under 750*l.*: of two the value is not given in the 'Clerical Guide,' our authority in this matter; and three are united with other benefices, viz., the rectory of Llan Dyrnog, with the bishopric of Bangor; the rectory of Llan Rhydd, with the wardenship of Ruthen; and the chapelry of Cyffylliog, with the vicarage of Llan Ynys. The ecclesiastical patronage of the bishop of St. Asaph in this county is very valuable: he has the right of presentation to thirty-six livings, of which twelve are of the yearly value of 300*l.*, and under 500*l.*, and six of the yearly value of from 500*l.* to 750*l.*

Denbighshire is included in the North Wales circuit: the assizes are held at Ruthen; and the quarter-sessions alternately at Ruthen and Denbigh; the Easter and Michaelmas sessions at the former, the Epiphany and Trinity sessions at the latter. Denbigh is the chief place of county election: the polling stations are Denbigh, Wrexham, Llan Rwt, Llan Gollen and Ruthen.

History, Antiquities, &c.—Denbighshire, before the conquest of South Britain by the Romans, was comprehended in the territory of the Ordovices, a powerful tribe, into whose dominions Caractacus in his last struggle against the Romans transferred the seat of war, and whose subjugation was not completed till the time of Agricola. There can be no doubt of the complete conquest of Denbighshire, as well as of the rest of North Wales by the Romans; but no trace of their dominion is found within the county at the present day, unless it be some lead-works, near Llan y Myneich: nor is it clear that any of their roads crossed it, except that which connected their stations of Varæ (Bod-fary in Flintshire), and Conovium (Caer Rhun or Caer Hen, near Aberconwy). In their division of the conquered part of the island, Denbighshire was included in Britannia Secunda. Of monuments of the time preceding the Roman conquest, may be noticed two, Kistvaens or stone cells (probably sepulchral) mentioned by Camden: and perhaps the tumuli at Llan Armon yn Yale, the opening of one of which is described by Mr. Pennant. (*Tour in Wales*, London, 1784, vol. i., p. 408.) A pass through the Clwydian hills is supposed to indicate by its name (Bwlch Agricla) the route which Agricola took in his expedition against Mona. At Abergely or Abergeley on the coast, are the remains of a British post, called Coppâ yr Wylfa, or the Mount of the Watch Tower; but we know not to what period it is to be referred.

When the Saxons established themselves in Britain, Denbighshire, as being on the frontier towards Mercia, one of the kingdoms of the heptarchy, or rather octarchy, established by that people, became the scene of frequent struggles. To the time of these struggles we may refer some

existing monuments, as the pillar of Eliseg, noticed above in our account of Llan Gollen; and the famous dyke or ditch, called Offa's dyke, made by Offa, king of Mercia, as a barrier against the predatory incursions of the Welsh. This ditch is strengthened at intervals by small forts on artificial mounds, which mounds yet remain. The ditch is on the Welsh side of them. The dyke crossed that detached part of the county which is contained in the parish of Llan y Myneich, and entered Denbighshire by the hills on the south side of the valley of the Ceiriog. It ran (though with a somewhat circuitous course) towards the north, passing near Chirk castle and Ruabon, and so into Flintshire, thus inclosing the eastern part of Denbighshire, within the Mercian frontier. Although insufficient as a military work to keep off all ravages from the country which it was designed to protect, it was the recognized boundary of England and Wales; and heavy penalties were denounced against all Welshmen who should be found in arms on the English side. A dyke, called Wat's or Watt's dyke, equal to that of Offa in depth, though not in extent, runs parallel to it through this county. It enters Denbighshire two or three miles to the East of Offa's dyke, crosses the Ceiriog and the Dee, and runs through Wynnstay (once called Wattstay) park, past Wrexham and across the Alyn into Flintshire. It was formerly strengthened in its course by forts; the site of one of these at Erddig, between Ruabon and Wrexham, is marked by earth works and some remains of masonry.

About the year 828, Denbighshire was overrun by Egbert, king of Wessex, who had acquired for that kingdom the permanent supremacy of the Anglo-Saxon kingdoms. The incursions of the Danes prevented the Saxons from entirely subduing the antient Britons; and indeed these seem to have recovered, by the aid of the Northern Britons, the territory appropriated by Offa, whose dominions, as we have seen, included part of Denbighshire. The country thus restored to its original masters was included in Powys or Powysland, one of the subdivisions of Wales. The consolidation of the power of England under the Norman princes again subjected the Welsh to the pressure of a superior hostile power; they struggled gallantly, and the victory which Owen Cyfeiliog, who flourished in the twelfth century, obtained near Ruabon, has been already noticed. Denbighshire fell into the power of Edward I. in 1277, being ceded by Llewelyn, the last prince of North Wales, at the close of his first struggle with the ambitious and politic king of England. In the subsequent revolt of the Welsh prince and his brother David, in 1282, it reverted to its native masters, but the death of Llewelyn and the execution of David as a traitor, again and finally placed it under the English dominion.

In the insurrection of Owen or Owain Glyndwr (a descendant of the Gryffydd ap Madog mentioned above), in the civil war of the Roses, and again in the great civil war of the seventeenth century, Denbighshire became the scene of contest. In 1643 Holt Castle, which has been in the hands of the Crown, was seized for the Parliament by Sir William Brereton and Sir Thomas Myddleton, but was recovered by the Royalists. In 1645 a considerable body of Welsh and Irish Royalists under the command of Sir William Vaughan, marching to the relief of Chester, then besieged by the Parliamentarians, were attacked near Denbigh, by a detachment of the latter (1000 foot and 1400 horse), under General Mytton, and Colonels Jones and Louthian, and entirely routed; 500 horse and 400 foot were taken prisoners, 100 men were killed, and the remainder dispersed. In February 1645-6 the castles of Ruthen and Holt were simultaneously attacked by Mytton, and surrendered after a siege of two months. The conqueror then marched to Denbigh, the castle of which he besieged in July; it held out till November, when it surrendered on honourable terms. In the year 1659 Sir Thomas Myddleton and Sir George Booth made a premature attempt to restore the Stuarts. Denbighshire has not been the scene of any public event of interest since that time.

(Authorities—*Beauties of England and Wales*; *Boundary Reports*; *Population Returns and Parliamentary Returns relating to Education*; *Clerical Guide*; Pennant's *Tour in Wales*; Carlisle's *Topographical Dictionary of Wales, &c. &c.*; Mogg's *Edition of Paterson's Roads*; Greenough's *Geological Map of England*; Walker's *do.*; *Physical and Political Geography of the British Isles*, in

* This number we give with some hesitation: it is only by a comparison of the population returns with the 'Clerical Guide' that we have been able to ascertain the number.

the *Library of Useful Knowledge*; Conybeare and Phillips's *Outlines of the Geology of England*.)

It is well to observe that the account of Denbighshire in the *Beauties of England and Wales* is a very hasty and confused compilation, especially in the historical part.

STATISTICS OF DENBIGHSHIRE.—Population. Denbighshire is principally an agricultural county. Of 20,120 males, twenty years of age and upwards, residing in 1831

in Denbighshire, 10,353 were engaged in agricultural pursuits, and only 235 in manufactures or in making manufacturing machinery; about 200 of these latter were weavers of woollen goods, half of whom lived at Llangollen and Llan-Saintffraid-Glynn-Ceiriog, the rest were scattered throughout the county.

The following summary of the population, taken at the last census (1831), shows the number of inhabitants and their occupation in each hundred of the county.

[HUNDREDS, &c.]	HOUSES.				OCCUPATIONS.			PERSONS.			Males twenty years of age.
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other families not comprised in the two preceding classes.	Males.	Females.	Total.	
Bromfield . . .	5,281	5,527	48	427	1,807	1,793	1,927	13,162	13,297	26,459	6,296
Chirk . . .	2,221	2,356	3	55	1,079	581	696	6,148	5,900	12,048	2,992
Isaled . . .	2,702	2,779	16	118	1,919	443	417	6,887	6,920	13,807	3,373
Isdulas . . .	2,485	2,590	15	82	1,499	599	492	6,084	6,079	12,163	3,004
Ruthen . . .	2,193	2,345	17	61	1,179	535	631	5,379	5,750	11,129	2,681
Yale . . .	744	767	1	37	393	127	247	2,013	1,837	3,850	995
Denbigh (borough)	742	786	6	52	259	400	127	1,558	2,228	3,786	779
Militia under training . . .	..	..	..	..	..	..	..	387	..	387	..
Totals . . .	16,368	17,150	106	832	8,135	4,478	4,537	41,618	42,011	83,629	20,120

The population of Denbighshire at each of the four enumerations was as follows:—

	Males.	Females.	Total.	Inc. per Cent.
1801 . . .	..	..	60,352	..
1811 . . .	..	..	64,240	6.44
1821 . . .	37,785	38,726	76,511	19.10
1831 . . .	41,618	42,011	83,629	8.69

An increase is here seen between the first and last periods of 23,277 persons, or more than 38½ per cent., which is 18½ per cent. below the general rate of increase throughout England.

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the three dates of—

1811 were £32,427, which was 10s. 1d.	for each inhabitant.
1821 ,, 32,658 ,, ,, 8s. 6d.	
1831 ,, 35,126 ,, ,, 8s. 5d.	

The sum expended for the same purpose in the year ending March, 1836, was 30,204*l.*; and assuming that the population has increased at the same rate of per-centage since 1831 as in the ten years preceding that period, the above sum gives an average of 6*s.* 10½*d.* for each inhabitant. All these averages are below those for the whole of England and Wales.

The sum raised in Denbighshire for poor's-rate, county-rate, and other local purposes, in the year ending 25th March, 1833, was 44,668*l.* 4*s.*, and was levied upon the various descriptions of property as follows:—

	£.	s.
On land . . .	39,163	15
,, dwelling-houses . . .	4,553	4
,, mills, factories, &c. . .	367	19
,, manorial profits, navigation, &c. . .	583	6
	44,668	4

The amount expended was:—

For the relief of the poor . . .	36,815	5
In suits of law, removal of paupers, &c. . .	1,108	9
For other purposes . . .	6,689	1
Total . . .	£44,612	15

In the returns made up for the subsequent years, the descriptions of property assessed for local purposes are not distinguished. The sums raised in the respective years ending March, 1834, 1835, and 1836, were 41,531*l.* 16*s.*, 41,242*l.* 8*s.*, and 39,461*l.* 19*s.* The expenditure was as follows:—

	1834.	1835.	1836.
For the relief of the poor	£33,135 15	31,668 0	30,203 11
In suits of law, removal of paupers, &c.,	1,440 5	832 4	837 12
For other purposes . . .	7,139 0	8,946 15	8,123 0
	£41,715 0	41,446 19	39,184 3

The saving effected in the sums expended for the relief of the poor in 1836, as compared with the expenditure of 1834, is therefore 2,932*l.* 4*s.*, or nearly 19 per cent.; including the other two items the whole amount of saving is reduced to 2,531*l.*, or rather more than 6 per cent.

The number of turnpike trusts in Denbighshire, as ascertained in 1834, was six; the number of miles of road under their charge was 165; the annual income arising from the tolls and parish composition was 4,034*l.* 5*s.* 4*d.*, and the expenditure was 3,906*l.* 1*s.*

The county expenditure in 1834, exclusive of the relief for the poor, was 5,253*l.* 17*s.* 11*d.*, disbursed as follows:—

	£.	s.	d.
Bridges, buildings, and repairs, &c. . .	887	16	3
Gaols, houses of correction, &c., and maintaining prisoners, &c. . .	677	5	2
Shire halls and courts of justice—building, repairing, &c. . .	292	15	0
Prosecutions . . .	1,153	1	11
Clerk of the peace . . .	347	5	8
Conveyance of prisoners before trial . . .	80	19	2
,, of transports . . .	111	19	3
Constables—high and special . . .	18	2	0
Coroner . . .	92	12	0
Debt, payment of, principal and interest . . .	1,219	12	1
Miscellaneous . . .	372	9	5
Total . . .	5,253	17	11

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 141, 150, and 270; making an average of 20 annually in the first period, of 21 in the second period, and of 38 in the third period. The number of persons tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 13, 10, and 12 respectively. Among the persons charged with offences there were committed for—

	1831.	1832.	1833.
Felonies . . .	12	9	11
Misdemeanors . . .	1	1	1

The total number of committals in each of the same years was 14, 18, and 13, respectively; of whom

	1831.	1832.	1833.
The number convicted was	11	15	6
„ acquitted	3	2	5
Discharged by proclamation	0	1	2

At the assizes and sessions in 1835, 50 persons were charged with crimes in Denbighshire; out of which number 13 had committed offences against the person, 9 of which were common assaults; 6 were charged with offences against property, committed with violence, and 25 for offences against property, committed without violence. Of the remaining 6, there were 3 committed for poaching, 2 for refusing to aid peace-officers, and 1 for sending a threatening letter. Of those committed, 31 were convicted, and 19 acquitted, or no bill found against them. Of those convicted, 3 were transported, 25 were imprisoned, 22 of them for six months or under, 1 was fined, 1 whipped, and 1 discharged on sureties. Of the offenders, 47 were males, and 3 females. Among the whole number, 14 could read and write, 19 could read only, and 16 could neither read nor write; the degree of instruction of 1 was not ascertained. The proportion of the offenders to the population in 1835, was 1 in 1673.

The number of persons qualified to vote for the county members in Denbighshire is 3538, being about 1 in 24 of the whole population, and rather less than 1 in 6 of the male population above 20 years of age, as taken at the census of 1831. The expenses of the last election of county members to parliament were to the inhabitants of the county 107*l.* 18*s.* 10*d.*, and were paid out of the general county rate.

There are two savings-banks in this county. The number of depositors, and amount of deposits on the 20th November, 1832, 1833, 1834, and 1835, respectively, were:—

	1832.	1833.	1834.	1835.
Number of depositors	331	945	1011	1104
Amount of deposits	£9432	28,919	30,952	32,690

The various sums placed in the savings-banks in 1834 and 1835 were distributed as under:—

		1834.		1835.	
		Depositors.	Deposits.	Depositors.	Deposits.
Not exceeding .	£20	510	£3,825	598	£4,389
„	50	318	9,420	311	9,320
„	100	116	7,924	126	8,744
„	150	46	5,720	37	4,341
„	200	15	2,510	26	4,298
Above	200	6	1,553	6	1,598
		1,011	£30,952	1,104	£32,690

Education.—The following particulars are obtained from the parliamentary enquiry on education made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant Schools	8		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		59	
Females		72	
Sex not specified		187	
		318	
Daily Schools	141		
Number of children at such schools, ages from 4 to 14 years:—			
Males		2355	
Females		1909	
Sex not specified		1166	
		5,430	
Schools	149		
Total of children under daily instruction		5,748	
Sunday Schools	211		
Number of children and others at such schools, ages from 4 to 10 years:—			
Males		4,783	
Females		4,154	
Sex not specified		11,836	
		20,773	

Assuming that the population between 2 and 15 years has increased in the same ratio as the whole of the population between 1821 and 1831, and that it has continued to the time (1834) this return was made in the same uniform rate of increase, there must have been living in Denbighshire 23,892 persons between those ages. A very large

number of scholars attend both daily and Sunday schools. Twenty-four Sunday schools are at places where no other schools are established, and therefore the scholars attending them, 1756 in number, cannot be supposed to attend any other schools. But at all other places the pupils of the Sunday schools have likewise the opportunity of resorting to the daily schools; of what number duplicate entry is thus made cannot be ascertained. Of fourteen schools, which are both daily and Sunday, and which contain 764 scholars, duplicate entry is known to have been made. Besides this cause of uncertainty as to the exact number of children under instruction, most of the Sunday schools consist of adults and aged persons, as well as children, rendering the number of the latter much less than the total number of scholars as given in the return. We may therefore conclude that not nearly the whole of the children between the ages of 2 and 15 are receiving instruction in this county.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscrip. and payment from scholars.	
	Schls.	Scho-lars.	Schls.	Scho-lars.	Schls.	Scho-lars.	Schls.	Scho-lars.

The schools established by Dissenters, included in the above statement, are:—

	Schools.	Scholars.
Infant Schools	—	—
Daily „	8	302
Sunday „	154	14,411

The schools established since 1818 are:—

Infant and other daily schools	70	2,000
Sunday Schools	174	15,404

Twelve boarding-schools are included in the number of daily schools as given above. No school in this county appears to be confined to members of the established church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists. Lending libraries of books are attached to five schools in Denbighshire.

DENDER. A river in Belgium, which takes its rise in the province of Hainault, about five miles north of Mons, and near the small town of Leuze. Its course is first north-north-west to Ath, where it turns to north-north-east, and enters the province of East Flanders, near Grammont: it passes through the towns of Ninove and Alost, and unites with the Scheldt at Dendermonde about fifty-two miles from its source. The Dender is navigable as far as Ath, forty miles from its mouth, to effect which object some works have been executed between Alost and Dendermonde.

DENDERAH, the Tentyra of the Greeks and Romans, a ruined town of Upper Egypt, near the left or west bank of the Nile, and nearly opposite Keneh, is celebrated for its temple, which is the best preserved and one of the most splendid in all Egypt. Its remains occupy a vast extent of ground, and consist of various buildings and propyla, besides the temple itself. They are enclosed, with the exception of one propylon, within a square wall, the side of which is 1000 feet, and built of sun-dried bricks. The wall is in some parts 35 feet high and 15 feet thick. Dr. Richardson, who has given a description of this temple, as well as Belzoni, Hamilton, and others, assigns its erection to the period of the Ptolemies. The handsome portico in front is formed of 24 columns ranged in four rows, with quadrangular capitals, having a colossal head of Isis, or, as some say, of Athor, on each side, surmounted by another quadrangular member, each face of which contains a temple doorway with two winged globes above, and other decorations. (*British Museum, Egyptian Antiquities, in the Library of Entertaining Knowledge.*) The shafts of the columns are perfectly cylindrical and of equal diameter all through, and the whole height, including the base, the quadrangular capital, and dé above that, is 46.10 English feet. The front is adorned with a beautiful cornice and a frieze covered with figures and hieroglyphics, over the centre of which the winged globe is predominant. On

all the walls, columns, architraves, and ceiling, there is no where a space of two feet that is not covered with some figures in basso-relievo of human beings, animals, plants, emblems of agriculture, or of religious ceremonies. The interior chambers of the temple are likewise covered with sculptures, among which the figure of Isis is repeated in numberless instances, as she appears to have been the presiding deity of the place. The light in the chambers comes in through small holes in the wall; the sanctuary itself is quite dark. The ceiling of the portico is occupied by a number of mythological figures, among which the French savans thought they recognised the signs of the zodiac; but Dr. Richardson observes that the number is incomplete, as the Crab is wanting, and he, with other recent travellers and archaeologists, is of opinion that it is no zodiac, but a collection of mythological emblems, without any reference to astronomy. On the east side of the temple there are some apartments, both on the ground floor and upper story. On the ceiling of one of the latter, under the roof of the temple, there was another assemblage of mythological figures resembling those on the ceiling of the portico, though fewer in number and differently arranged. This was called a planisphere or zodiac, because in the middle of it figures similar to the signs usually adopted to represent the 12 constellations were observed. 'The ceiling is encompassed with three broad circular lines, and it is only the central space that is occupied with this mythological table, which appears as if supported by twelve figures, four females, one above each angle of the room, and the other eight distributed in pairs between, and having hawks' heads. In the middle of this assemblage of emblems are certain figures, which have been taken for the signs of the zodiac, ranged in a sort of circular order, but without any regularity of distance. The lion, the bull, and the vase-carrier are exactly above three of the female figures that extend from three of the corners of the room to support the tablet with their heads; Scorpio, for the sake of regularity, should have been above the head of the fourth female figure, but it is not, neither is Libra. Capricornus, Sagittarius, Scorpio, and Libra are all crowded without any regularity into one division, and instead of the Crab we have a broad-backed spider.' Richardson (*Travels along the Mediterranean and parts adjacent*, in 1816-17, from which we have just quoted) observes that he compared the figures of the temple of Denderah with the engravings in the French work on Egypt, and found the latter a very incorrect representation. His opinion, with respect to this pretended zodiac, is the same as that concerning the one in the portico, namely, that it is not meant for a zodiac, but is a congregation of gods and goddesses and religious processions.

These zodiacs of Denderah have given rise to a warm discussion connected with the truth of the Mosaic history of the world. Dupuy and other French writers have assumed, from the relative position of these zodiacal signs and their connexion with the precession of the equinoxes, that the astronomical observations upon which these zodiacs were constructed must refer to a date far more antient than that recorded for the Deluge, or even the creation of man; not less, indeed, than 15,000 years, according to some calculations. According to Littrow and others, however, the date would only be 3228 years old. But there is, as we have observed, another opinion, strongly supported by Letronne, Halma, Champollion, and others, discarding altogether the notion of these ceilings of Denderah being intended as representations of the zodiac, or being in any way connected with astronomical observations. Those who may wish to examine the grounds of this controversy may consult the writers already quoted, and especially Letronne, 'Observations sur l'Objet des Représentations Zodiacales qui nous restent de l'Antiquité,' 8vo. Paris, 1824; N. Halma, 'Examen et Explications des Zodiacques Egyptiennes,' 8vo. 1822; and Supplement to do., concerning the Zodiac of Denderah; and also Visconti, Hamilton, Champollion, &c. It is now generally believed that the temple of Denderah, with its zodiacs, is not older than the period of the Ptolemies.

The so-called circular zodiac in the upper chamber of the temple of Denderah, which was sculptured on a kind of sandstone, was cut out of the ceiling by a Frenchman of the name of Lelorrain, with the permission of Mehemet Ali Pasha, and shipped for France in 1821, when it was purchased by the French government, and is now in the Museum at Paris.

DENDERMONDE, a town in East Flanders, the chief place of an arrondissement of the same name, is built at the confluence of the Dender and the Scheldt, about 14 English miles east from Ghent, and the same distance north-west from Brussels. The town contains 7,238 inhabitants: there are 1,014 houses, 4 churches, 5 chapels, a town-house, an hospital, a lunatic asylum, an orphan house, two convents, 14 schools, and a college. The town, which is fortified and defended by a citadel built in 1584 by the Duke of Parma, is said to have been founded in the eighth century. It was besieged by Louis XIV. in 1667, with 50,000 men, who were obliged to retire by the opening of the sluices on the part of the besieged, whereby the surrounding country was laid under water. In 1745 it fell into the hands of the French.

Dendermonde is the seat of many branches of manufacture, the most important of which are woollen cloths, hats, soap, cordage, and pottery. The surrounding country is fertile and well cultivated, and considerable business is transacted at the weekly market in grain, linseed, hemp, and oil. Many Roman antiquities have been dug up in the neighbourhood.

(Van der Maelen's *Dictionnaire Géographique de la Province de la Flandre Orientale*.)

DENDROBIUM, an extensive genus of East Indian epiphytes, found in the whole of the damp tropical parts of Asia, and a little beyond the tropics in Japan and New Holland, but unknown in the rest of the world. About a hundred species are enumerated by systematic writers; *D. Pierardi*, *cucullatum*, *chrysanthum*, *aureum*, *fimbriatum*, *moschatum*, *densiflorum*, *pulchellum*, *nobile*, and a few more, are known in the collections of this country; but a large proportion of the remainder requires to be better described and more carefully examined.

DENDROCITTA. [CORVIDÆ, vol. viii., p. 69.]

DENDROCOLAPTES. [CREEPER, vol. viii., p. 148.]

DENDRO'COPUS. [CREEPER, vol. viii., p. 148.]

DENDRO'DOA (Zool.), Mr. W. S. Mac Leay's name for a subgenus of Ascidians belonging to the aberrant group, or those which have a branchial pouch with only eight folds, the tentacula simple, and no liver.

Subgeneric Character.—(External). *Body* subcylindrical, with both orifices exceedingly minute, and situated on the apex. (Anatomical). *Branchial pouch* marked with only eight folds, and having the reticulation continuous. *Orifices* terminal. *Tentacula* simple. *Liver* none. *Ovary* unique, branched, situated beneath the mantle and the branchial pouch. (W. S. Mac Leay.)

Example.—*Dendrodia glandaria*. The following is Mr. Mac Leay's description. *Body* subcylindrical, with a round summit. *Envelope* whitish, subpellucid, coriaceous, and smooth, having its base rough with agglutinated pebbles: internally it has a pearly lustre, and is thickest towards the base. *Orifices* so little prominent as to be scarcely perceptible without a lens; separate from each other, and opening with four indistinct rays. *Mantle* muscular, but of uniform substance.

Tentacula about twenty-six, simple, subulate, alternately long and short.

Anterior nervous tubercle with many spirals.

Branchial cavity occupying the whole length of the animal.

Pharynx situated at the bottom of the cavity of the body. *Œsophagus* descending, and turning short round near the cardia into a cylindrical horizontal stomach, which is striated internally, and occupies with the pylorus (which turns round and lies parallel to it) the whole of the bottom of the cavity. *Intestine* very long. *Rectum* ascending, almost vertical, terminated by an anus margined.

Ovary one, situated on the left side, between the branchial pouch and the tunic. It consists of a trifurcated cylindrical stem, having at the base on one side a forked branch, on the other a simple one, all of the same thickness. Mr. Mac Leay remarks that the organs of digestion have great affinity in external structure and position to those of *Cynthia pantex* of Savigny, except that the stomach and intestine are horizontal, and the anus simply margined, and that, different as this species is in external appearance from all other *Ascidia*, internally it agrees with the *Pandocia* in almost every essential respect but the ovary. He observes that this singular animal completes the circle of the genus *Ascidia* in the most beautiful manner. It agrees with the first subgenus, *Cynthia*, in the nature of its branchial reti-

culatation and of its digestive apparatus; but *Cynthia* has two ovaries, the right one contained in the intestinal loop, and the left one coating the tunic. The first of these, or the right ovary, is the only one possessed by *Pandocia*, and the left is the only one possessed by *Dendrodoa*. Mr. Mac Leay concludes by stating that the distinction between the aberrant groups of *Ascidia* depends thus upon the nature of their system of generation, as that which exists between the two normal groups depends on their system of respiration.

a, *Dendrodoa glandaria*, natural size seen on the right side. The base encrusted with pebbles, has the appearance of the cup of an acorn. *b*, The same seen obliquely, so as to show the top, which is a little compressed, and exhibits four points. The two lowest and largest are false orifices; the two smallest (which are so small as to be almost invisible to the naked eye) are the real orifices, the highest being the anal, and the other the branchial orifice. ('Anatomical Observations on the Natural Group of Tunicata, &c.,' by William Sharp Mac Leay, Esq., A.M., F.L.S., &c.; 'Linn. Trans.' vol. xiv., p. 547, to which the reader is referred for the magnified anatomical figures and details.)

DE'NDROMUS (Zoology), a genus of rodent quadrupeds, established by Dr. A. Smith in his 'Contributions to the Natural History of South Africa,' with the following characters:—

$$\text{Dental formula, } \frac{2}{2} : \text{molars, } \frac{3-3}{3-3} = 16.$$

The upper incisors with a longitudinal furrow on their anterior face; the lower long, slender, with the cutting edge cuneated.

The *upper* first molar with six tubercles in a double row, and two indistinct ones besides, of which one is at the anterior part of the crown of the tooth, the other near another tubercle of the internal series, behind the transverse incisorial lamina; the second molar with two or three longitudinal incisorial laminae by the external margin of the crown, in the middle of which lie three or four obtuse transverse tubercles disposed in a row; the third molar has two transverse incisorial laminae with an interjacent furrow. *Below*, the first molar has six tubercles disposed in a double series; the second, four obtuse tubercles arranged in the same order; the third is very small, with some transverse laminae and furrows intermingled. No canines. Rostrum acute. Lip slit. Ears oblong, rather naked, and, internally, near the skull, with two transverse membranaceous valvules, of which the lower lies over the external auditory meatus. Tail elongated, annulated, with scattered hairs. Feet divided, ambulatory; the anterior with three toes and a wart in lieu of hallux; the posterior five-toed: claws falcular.

Example.—*Dendromus Typus*. Above, brown, passing to ferrugineous; beneath, reddish white; whiskers long, partly black and partly white; upper lip white; ears without and within slightly covered with a fine short white reddish fur; extremities the same; tail pointed, considerably longer than the body, and of a faint grayish brown colour; along the centre of the back, particularly towards the tail, an indistinct black line. Length from point of nose to root of tail, $3\frac{1}{2}$ inches; length of tail, $4\frac{1}{2}$ inches.

Locality.—South Africa, upon the branches of trees, &c., in which situations it constructs its nest and brings forth its young. Dr. Smith observes that the position of this little animal among the family of mice is not well determined; but that perhaps its place is after the *Mouse*. (*Zool. Journ.*, vol. iv. p. 438.)

DENDRONESSA. [Ducks.]

DE'NDROPHIS, (Fitzinger), a subgenus of serpents placed by Cuvier under the great genus *Coluber*, and stated by him to be the *Ahetulla* of Gray. The species of this genus have, like the *Dipsas* of Laurenti, a line of wider scales along the back, and narrower scales along the flanks, but their head is not larger than their body, which is very slender and elongated. Their muzzle is not elongated, and they are not venomous. *Locality*, India and Africa. [LEPTOPHIS.]

1, *Dendrophis Ahetulla*, one fourth of the natural size. 1 *a*, head. 1 *b*, Disposition of the scales above and below the vent. (Iconog.)

DENDROPHYLLIA. [MADREPHYLLICEA.]

DE'NDROPLEX, a genus of birds established by Mr. Swainson, and placed by him in the family *Certhiadae* (Creepers), and sub-family *Certhiana*, which have the tail graduated and rigid.

Generic Character.—Bill very straight. Wings moderate, rounded; third, fourth, and fifth quills longest.

Mr. Swainson observes that he knows not whether the type of this genus has been described, and states that the living bird has all the manner of a *Picus*. Except in its perfectly straight bill, he adds, it differs not from *Dendrocolaptes*. (*Zool. Journ.*, vol. iii., p. 354.)

DENEB, an Arabic word, signifying the tail: it generally means the bright star (β) in the tail of the Lion. [LEO.]

DENHAM, SIR JOHN, born at Dublin in the year 1615, was son of Sir John Denham, who was some time chief baron of the Court of Exchequer in Ireland. His father being afterwards made a baron of the Exchequer in England, he was brought to London in 1617, where he received his grammatical education. In the year 1631 he became a gentleman commoner of Trinity College, Oxford, where, after studying for three years, he took the degree of bachelor of arts. He subsequently entered himself at Lincoln's Inn, studied the law pretty closely, and might have done well, had not an immoderate passion for gaming ex-

hausted his money, and drawn on him the displeasure of his father. He however abandoned the mischievous pursuit, and wrote an essay against gaming, by which he regained his father's favour, though his reformation appears to have been somewhat feigned, as immediately after his father's death his fondness for play returned. In 1641 he gained great celebrity by his tragedy of 'The Sophy,' which was acted at Blackfriars with much applause; and his fame was increased by his 'Cooper's Hill,' written in 1643, almost the only one of his poems that is now read. In the year 1647 he performed many secret and important services for Charles I., when prisoner in the hands of the army, which being discovered, he was forced to escape to France. In 1652 he returned to England, and resided at the earl of Pembroke's; and at the restoration of Charles II. he was appointed surveyor-general of his Majesty's buildings, and created knight of the Bath. He died in the year 1688, his understanding having been for some time impaired by domestic grievances.

The admirers of Denham usually limit their praises to 'Cooper's Hill,' and some lines on the earl of Strafford; while others confine their commendations to two lines in the former poem, wherein he describes the Thames:

'Tho' deep, yet clear; tho' gentle, yet not dull,
Strong without rage, without o'erflowing full.'

This is a most happy combination of words; the bringing into contrast expressions which only vary in shades of meaning is highly ingenious. The whole passage relating to the Thames is written with much spirit, and striking lines might be selected from other parts; yet, taken as a whole, the poem is heavy and purposeless, and though short, is very tedious.

Readers of the present day, on perusing the poems of Denham, will doubtless wonder what could be the cause of the high commendations bestowed on him by his contemporaries; but to look at him from a fair point of view, and to assign him his due portion of merit, it will be necessary to consider him as one of the reformers of English verse. At the beginning of the seventeenth century the art of versification was in a very imperfect state, as may be seen from reading the prologues to our early dramas; and hence a poem of the length of 'Cooper's Hill,' written with tolerable smoothness, was something remarkable. At the present day, even the versification of Denham appears faulty, as he frequently allows a sentence to run from one line into another, a practice which, though effective in blank verse, is intolerable in rhyming couplets; and indeed he has made some words rhyme in a manner that we wonder was endured by any age; for example, in one instance he makes 'sprung' rhyme with 'Rome.' Those who wish to observe the progress of their own language will find the reading of such authors as Denham not unprofitable; and Johnson's *Lives of the Poets* form a good running commentary.

DENHAM. [AFRICA.]

DENIER, from the Latin *denarius*, a French coin, originally of silver. It continued in use, through different modifications, as long as the old system of coinage in France lasted; that is, till 1795. Up to that time, accounts were kept in France in livres of 20 sous or 240 deniers: they have been since kept in francs of 10 decimes, or 100 centimes.

Under the kings of the first race the denier weighed twenty-one grains; under the second race, and in the time of Charlemagne, twenty-eight, and sometimes thirty grains; and under Charles the Bald thirty-two. At the commencement of the third race of French kings the denier weighed twenty-three or twenty-four grains of fine silver. Philip I. began the practice of mixing copper with the silver; and it is in his time that we find the distinction first made between *deniers Tournois* and *deniers Parisis*, the latter being worth a fourth part more than the former. By the time of St. Louis, 1226, the denier had become so debased as to contain not more than six grains and a half of silver; which was probably the occasion of that monarch's issuing a larger class of coins called *gros deniers d'argent*. The term denier was likewise afterwards applied to the gold money of France, in the same manner as the gold first issued by our Henry III. was termed the gold penny.

There were formerly current in France several little copper pieces, which, having no proper name, were distinguished only by their value in deniers; such were the pieces of 36, 30, 24, 18, 12, 6, 4, and 2 deniers. The pieces of 4 and 2 deniers were coined at Strasburg, for currency

in the province of Alsace, pursuant to a declaration of the 6th September, 1695. Those of 6 deniers were coined in the mints of Aix, Montpellier, Rochelle, Bourdeaux, and Nantes, by an edict issued in the month of October 1709.

The deniers coined toward the end of Louis XIII. were the work of the famous Varin, and are much admired for their execution.

(Le Blanc, *Traité Historique des Monnoyes de France*, 4to. Paris, 1690; Furetière, *Diction. Universel*, v. *Denier*; Postlethwayt's *Dict. of Commerce*, fol. Lond. edit. 1774.)

DENIS, SAINT, a town in France, in the department of Seine, in a plain not far from the right bank of the Seine, and on the streamlets the Cloud and the Rouillon, which flow into that river: it is about 5 miles from Paris, in 48° 56' N. lat., and 2° 21' or 22' E. long.

This town dates its rise from the foundation of a church erected over the tomb of the saint and martyr whose name it bears. The church of St. Denis (Dionysius) was founded, or perhaps only enriched, by King Dagobert, in the seventh century. It had been preceded by a chapel built over the tomb of St. Denis, and rendered celebrated by reported miracles. Crowds of pilgrims resorted to the chapel, and afterwards to the church, and in the course of time a village rose round the sacred edifice, which increased to a considerable town. Dagobert founded also an abbey, which he richly endowed, and on which he conferred great immunities. Upon his death he was buried in the church of St. Denis: his successors in many instances followed his example, and the church became in time the customary burial-place of the kings of France. In 832 the monks had become so corrupt that the Abbot Hilduin had to introduce a thorough reform. The abbacy was soon after put in commendam by Charles le Chauve (who reigned from A.D. 840 to A.D. 877), and was subsequently held by many laymen; but Hugues Capet (who reigned A.D. 987 to A.D. 996) restored to the monks the right of choosing their abbot. During this interval the abbey was pillaged by the Northmen. One of the subsequent abbots, Suger, served the kings Louis VI. le Gros (who reigned from A.D. 1108 to A.D. 1137) and Louis VII. le Jeune (who reigned A.D. 1137 to A.D. 1180), both as a warrior and a statesman; and the oriflamme, previously the standard borne by the abbots in their private wars, became the standard of the royal forces. Suger vastly improved the possessions of the abbey, founded many priories, which he filled with monks of St. Denis, and rebuilt almost the whole of the church in a more magnificent style than heretofore. Part of the present edifice dates from this epoch. Mathieu de Vendôme, a subsequent abbot, administered the affairs of state during the second absence of Louis IX. (St. Louis) beyond sea: the rebuilding of a portion of the church which some of his predecessors had begun, was finished by him. The first monks of St. Denis were Benedictines; but they had so many privileges and prerogatives peculiar to themselves, that they may almost be regarded as the heads of a distinct order, having many subordinate priories in different parts of France: they were besides subject to no other superior than the pope himself. They have sometimes been called Dionysians. They had the keeping of the crown, sceptre, and other ornaments used at the consecration and coronation of the kings of France. About the time of Louis XIV. the grandeur of this establishment was much impaired. It was reduced to the ordinary rank of a Benedictine abbey, its revenues were partly applied to the support of the establishment of St. Cyr [CYR, ST.], and the ecclesiastical jurisdiction which the abbot had exercised over the territory of St. Denis was replaced, except as to the abbey itself, by that of the archbishop of Paris. The abbey was finally suppressed in 1792.

The present abbey-church, built at various epochs, presents great variety of style. The western front is divided by buttresses into three compartments, which are crowned by a range of battlements. In each compartment is a wide semicircular arched doorway, the ascent to which is by a flight of steps running along the whole front. Over the centre doorway are three pointed arches as though designed for windows, but only one is used for that purpose: over the side doors two tiers of arches, chiefly pointed, but of smaller dimensions; some of them are used as windows, or have in them smaller openings for windows. The upper part of the centre compartment is occupied by the clock. The two outer compartments are surmounted by towers which differ in their architecture; both however have

windows, with pointed arches, and that at the northern extremity is crowned by a tall spire. The other is crowned by something between a spire and a high ridged roof. The doors are covered with grotesque bronze figures in low relief: they were formerly gilt in or-molu.

The choir of this church contained the tombs of most of the kings of France, and of several other individuals eminent for their rank or ability, as Bertrand du Guesclin, Turenne, Montesquieu, and others. In 1793 a decree passed the convention for the destruction of the tombs of St. Denis; but it was so far moderated that a commission was appointed to preserve those monuments which should be deemed worthy of such a favour. The tombs of the kings were opened, and the bodies deposited in a common grave. The tomb of Turenne, who was buried here, was subsequently transported by order of the Directory to the Musée des Monumens François; and ultimately by Bonaparte to the church of the Hôtel des Invalides.

In 1794 it was in agitation to destroy the church of St. Denis altogether, but nothing further was done than to strip the lead off the roof. The roof was subsequently half covered with tiles in 1796; but in 1797 this reparation was stopped, and the project of destruction again agitated, but without being carried into effect. In 1799 the stained glass windows were removed. Under the consulate and the empire the church was restored; and in 1806 Napoleon issued a decree that St. Denis should be the place of sepulture of the emperors of his dynasty; that a chapter of ten canons, retired bishops, should be established, and that four chapels should be erected, three over the place where the tombs of the kings of the three races had stood, the fourth in the place destined for the burial of the emperors. In the chapels of the kings tablets of marble were to be put up, with the names of the kings whose tombs had previously occupied places in the church. Many of the royal tombs have been since replaced, and the abbey church is also adorned with paintings of historical events connected with the church, and with the statues of some of the earlier kings of France.

Next to the abbey, the most interesting object at St. Denis is the 'Institution Royale,' a school for the daughters of the members of the Legion of Honour, established in the buildings of the abbey. After the suppression of monastic institutions in France, these buildings were converted into a military hospital. Napoleon made it the place of one of the schools subsidiary to the establishment which he had formed at Ecouen, after the battle of Austerlitz, for the daughters of the members of the Legion of Honour. Upon the restoration of the Bourbons, Louis XVIII. united the institution of Ecouen to that of St. Denis, and placed them under the charge of the nuns of the 'Congrégation de la Mère de Dieu,' and fixed the number of pupils at 400. The establishment is under the direction of a lady superintendent, who has under her as assistants 37 ladies.

The trade of St. Denis is considerable. Printed calicoes and other cotton goods are manufactured: there are several establishments for washing wool and preparing it for the weaver; and others for bleaching linens, casting sheet lead, and making saltpetre, soda, and other chemical articles. There are also several flour-mills for the supply of Paris. The chief articles of trade, beside those manufactured in the place, are agricultural; corn, wine, vinegar, wood, wool, and cattle. There are several fairs in the year; three of them are held for eight or nine consecutive days, and there is one, called *La Foire du Lendit*, which occupies fifteen days. At these several fairs it is calculated that woollen cloths are sold to the value of 1,500,000 francs (62,000*l.* or 63,000*l.*), other woollen goods to the value of 200,000 francs (8000*l.*), linens to the value of 300,000 francs (12,000*l.* or 13,000*l.*), and cotton goods to the value of 800,000 francs (33,000*l.*). At the fair of *Lendit* 80,000 or 90,000 sheep are sold, which are brought from various departments, and some even from Würtemberg and other parts of Germany. The canal which communicates between the canal of the Ourcq and the river Seine joins the latter near St. Denis. There is hourly communication with Paris by voitures or carriages.

St. Denis had in 1832 a population of 9686. It is the capital of an *arrondissement*, containing 4 cantons, 36 communes or parishes, and (in 1832) 87,282 inhabitants. (Dulaure, *Histoire des Environs de Paris*; Malte Brun.)

DENIZEN. Denizen seems originally to have signified a natural-born subject. But now a denizen is an alien born, who has been constituted an English subject by letters of denization: he is in a kind of middle state be-

tween an alien and a natural-born subject. He may take lands by purchase, which an alien cannot; but he cannot take by inheritance, for his parent, through whom he must claim being an alien, had no inheritable blood. The issue of a denizen born before denization cannot inherit to him, but the issue born after may. A denizen cannot be a member of the privy council, or sit in either house of parliament, or hold any office of trust, civil or military, or be capable of any grant of lands, &c., from the crown. [ALIEN.]

DENMARK, or DANMARK (the land or Mark of the Dane), also termed the *Danske Stat* (the States of Denmark), is a kingdom lying, independently of its colonial possessions, between 53° and 58° N. lat., and 7° and 13° E. long. Its boundaries are, on the north, the Skager Rack, a gulf of the North Sea; on the north-east, the Cattegat, another gulf of the North Sea, which, with the Sound, separates Denmark from Sweden; on the south-east, the Ost-See, or Baltic; on the south, parts of the free states of Lübeck and Hamburg, the grand-duchy of Mecklenburg-Schwerin, and kingdom of Hanover; and on the west, the North Sea. Its colonial possessions consist of—Iceland, in the Atlantic; the Færoe islands (Faeroerne), in the North Sea; Greenland, in North America; five forts and their dependencies, on the coast of Guinea, in Western Africa; the islands of St. Croix, St. Thomas, and St. John, in the West Indies; the settlements of Tranquebar, on the Coromandel coast; the fort of Fredericsnagore, and town of Belasore, in Bengal; and the Nicobar group of islands at the entrance into the bay of Bengal.

The table in the following page presents a comprehensive view of the component parts, area, population, and principal towns of the Danish monarchy.

The subsequent details refer only to the European dominions of the Danish crown, viz., the insular portion, North Jütland, South Jütland or Schleswig, Holstein, and Lauenburg.

Continental Denmark, which may be designated the north-western peninsula of Germany, in its greatest length from north to south is about 304 miles; in its breadth it varies from about 33 to 106, the average being about 66. Its length of coast on the North Sea and Skager Rack is about 460 miles, and along the Cattegat, Little Belt, and Baltic, about 650; the whole extent of coast is accordingly not less than 1110 miles. Many parts of this long coast line are almost useless, in consequence either of the want of deep water, or of the numberless banks, bars, and islands which line it. The shores too of the islands that lie next the Baltic are so flat and irregular as to be unapproachable in most quarters by vessels which draw much water.

The surface of Denmark presents an almost uniform plain, elevated only a few feet above the level of the sea, but occasionally relieved by some small groups of hills, whose wooded summits break the monotony of the landscape, and, in combination with numerous inlets of the sea and small lakes, give the country a very pleasing appearance. The upper soil consists of a dense layer of clay or sand in most parts, mixed with gravel in some places; the sub-soil is a dark blue clay (*blaalaer*), entirely destitute of earthy matter, but partially intersected by a fine yellow sand. In some of the islands this clay is of a reddish tint. Remains of vegetable substances, but none of any large land-animals, are found in these clays. In North Jütland, the most sterile region in Denmark, the soil lies immediately upon a bed of bog-turf covered by sand from one to three feet in depth. Sands and heaths are the characteristic features in continental Denmark; and drift-sand renders a considerable portion of the western coasts almost uninhabitable. Together with extensive tracts of moors and swamps, the inland parts of Jütland and the islands are characterized by a rich marshy loam, of which bituminous marl is the chief constituent. The surface of the islands presents partial tracts of moor, heath, and woodland; but in general the soil is fertile, and well-suited to cultivation. The component parts of the 21,472 square miles of surface of which Denmark consists, are thus subdivided:—9850 square miles of sand capable of arable cultivation, 2830 of heath, 2660 of black rich earth, 1990 of loam and marl, 1050 of meadows and swamps, 902 of marshes, 940 of woods and forests, 735 of grazing grounds, 257 of drift-sand, and 258 of lakes and streams.

Denmark possesses no mountains, but a range of hills traverses the whole peninsula from south to north, keeping

in general near to the eastern coasts, and terminating with Cape Skagen (Skagens-Odde), the extreme point of North Jütland. Its loftiest points are the Himmelsberg, in the bailiwick of Skanderburg, North Jütland, which is 1200 feet high according to some, and 1800 feet according to others; the Dagbiørg-Daas, 700 feet, in the bailiwick of Viborg, and the Askehoy, 690 feet. There is also a range of hills, called the Fyen Alps, in the island of Fyen, or Fünen, which runs from the north-easternmost point to the south-easternmost at Svendborg, bending always towards the south-western coast: its highest summit does not exceed 400 feet. The chief mass of the Seeland hills inclines towards the eastern coast, and extends from the northern mouth of the Sound to the southernmost extremity of the island: the most elevated point is the Mangelberg, near Hirschholm, to the north-west of Copenhagen, which is 560 feet in height.

The western coasts of Jütland and Holstein are quite flat, and protected from the North Sea, or West Sea as it is termed by the Danes, in contradistinction to the Ost-See (East Sea, or Baltic), by sand-hills and dykes in South Jütland, or Schleswig. The eastern coasts of Jütland, as well as the island-coasts, are abrupt and precipitous, formed of chalk or limestone, and called Klinte by the natives: the Moens-klint, on the eastern side of the island of Moens, which stretches above ten miles out into the sea, is remarkable for its fossils and numerous waterfalls. The north-eastern shores of Seeland are separated from Sweden by the Sound, or Ear-Sound, (Ore-Sund, so denominated from the resemblance of its form to the human ear), the well-known entrance into the Baltic, which is about 70 miles in length from the Swedish point of Kullen-Cattegat to Falsterboe, and $1\frac{1}{2}$ mile (7986 feet) in breadth between Helsingør (Elseneur) and Helsingborg, where it is narrowest: in mid-channel it varies from 10 to 19 fathoms in depth. Between the western side of Seeland and the north-eastern side of the island of Fünen lies a second entrance into the Baltic, called The Great Belt, which is about 9 miles wide at its narrowest point between Nyeboeg and Korsøer, and varies from five to twenty-five fathoms in depth, but, on account of sandbanks and rocks, is difficult of navigation for large ships. Between the western coast of Fünen and eastern coast of Jütland and the island of Alsen, or Als, is a third entrance, called The Little Belt, which is not more than three quarters of a mile, or 4100 feet wide, next Middelfahrt, where it is most confined; it is about 46 miles in length, is hazardous to navigate, and just above Middelfahrt is commanded by the fortress of Fredericia, in North Jütland.

The coast of Denmark is indented in several parts with bays and inlets, here called Fiords, or Vügen, the latter name being applied to the smaller bays. The largest of these fiords are the Ise-Fiord, on the northern side of the island of Seeland, which is connected with the Roeskil-

der-Fiord on the east, and the Liim-Fiord on the west; it is about 74 miles in its greatest length, and contains several islands. The Liim-Fiord, which intersects North Jütland, occupies nearly 252 square miles; the Kingkiøpings Fiord is to the south of the last mentioned bay; and the Apenrade, Flensburg, and Eckenförd Fiords, on the eastern coast of South Jütland.

Denmark abounds in small lakes, the most considerable of which are—the Mos See (about 5 miles long and $1\frac{1}{2}$ broad), the Viborg, Skanderborg, Garboel, and Langesee, in Jütland; the Arrese, Esrumsee (celebrated for its fish, and united by a canal with the Great Belt), the Tüsssee, and Loroese, in Seeland; the Arreskoese in Fünen; the Marienboerse in Laaland; the Ploener and Selentersee in Holstein; and the Ratzeburgersee in Lauenburg.

As no inland point in Denmark is more than 35 or 40 miles from the sea, the country has no large rivers. The Elbe forms the southern boundary of Lauenburg, from the town of Lauenburg to the Hamburgese district of the Vierlande, and the south-western boundary of Holstein, from Altona to the Mas-Queller, where it discharges itself into the North Sea. The Danish streams which flow into it are the Delvenau, Bille, Alster, and Stoer. The largest of the navigable rivers of Denmark is the Eyder, which was considered the north-western boundary of the empire of the Franks in the days of Charlemagne, and of the German empire in after-times; it flows out of an inland sheet of water near Bördesholm in Holstein, passes westward through Rendsburg, and skirts Friedrichstadt, dividing Holstein from Schleswig, is navigable along nearly the whole of its course of about 105 miles, and enters the North Sea at Tönningen, at the south-western extremity of Schleswig, where it is 800 feet in width. The Trave, a Holstein river also, rises near Giselrade, flows southward through the Lauenburg and Lübeck territories, is navigable throughout the greater portion of its course of about 65 miles, receives the Steckenitz, and winding north of Lübeck, falls into the Baltic at Travemünde. The other streams which water Denmark and the adjacent islands, and to which the Danes give the name of Aae, scarcely deserve the name of rivers; the largest of them are the Gudenaee, in North Jütland, which rises in the Tyrrild Heide, in North Jütland, flows through several lakes, and enters the Cattegat near Randers; the Nipsaee, in Schleswig, which enters the North Sea at Ribe; the Schol, Wid, and Brede-aae, in the same duchy; and the Susaee, in Seeland, which flows into the sea at Nestwed.

Denmark contains four large canals. The Schleswig and Holstein or Eyder Canal, which connects the North Sea with the Baltic, was formed by rendering the Eyder navigable from Rendsburg to Kluvensik, whence the canal takes an easterly direction through the northern extremity of Lake Flembude, there crosses the range of hills which traverse the peninsula of Jütland and Schleswig

from north to south, and terminates in the Kieler Förde, a bay of the Baltic between Kiel and Friedrichsort. Its greatest elevation above the level of the Baltic is 27 feet; its length from Rendsburg to its termination is about 27 miles; it has seven bridges and as many sluices; is 100 feet broad at the surface, and 24 at the bottom; it is 10 feet deep, and capable of receiving vessels of 150 tons burthen. Its supply of water is derived from the Flembude lake. The Steckenitz Canal in Lauenburg, which unites the Elbe with the Baltic by connecting the Delvenau with the Möllner-See, Steckenitz, and Trave, was constructed in 1390, and establishes a communication between Lauenburg on the Elbe and Lübeck on the Trave. The Daneskiold Canal, on the island of Seeland, which was constructed by Count Daneskiold Samsoe, between the years 1810 and 1812, gives access from the south-eastern waters of the Great Belt to that quarter of the island which is richest in grain and timber; it begins at Noesdybroe, near Ringstedt, and is carried for about 23 miles to Nestwed, near the Baltic shore. The Odensee Canal connects Odensee, the capital of Fünen, with the sea.

Mineral waters have been brought into use at Glücksburg in Schleswig, and at Bramstede in Holstein; and there are saline springs near Oldeslohe, in the same duchy.

The proximity of the sea renders the climate of Denmark temperate, considering its latitude. The cold is greatest in North Jütland, and least in the adjoining islands. The weather is in general very variable; rains and fogs are of constant occurrence; storms are frequent; the winter cold is not severe, but the summer heats are at times overpowering. The humidity of the atmosphere is a great advantage to a country whose soil is of so sandy a nature. The thermometer seldom ranges above 20° Reaumur (77° Fahrenheit). The barometer varies from 28½° to 28° 6'.

The people of Denmark, with the exception of a few thousand Jews, resident in Copenhagen, Altona, and other towns, are of German descent, but of four distinct races. The Danes, who inhabit Seeland and the circumjacent islands, North Jütland, and a small portion of Schleswig, were the Normans of former times: they use a dialect of the German, and are estimated at 1,350,000: the pure Germans, who inhabit the duchies of Holstein and Lauenburg and the greater part of Schleswig, and whose numbers are computed at 650,000: the Frieslanders, who dwell along the western coasts of Schleswig and on the small islands in the North Sea: the Angles, who live between the Bight of Flensburg and the Schley on the Baltic, whose united numbers are estimated at about 70,000; and the Normans, who people Iceland and the Faeroe islands. The present population of Denmark, its duchies, and the adjacent islands, is about 2,040,000. In 1820, it was 1,662,000; in 1827, 1,932,153; and in 1833, about 2,000,000. The earliest census we possess is that of the year 1769 for Denmark Proper, which includes Jütland and the neighbouring islands: the then population was 786,000; in 1787 it had increased to 840,000; in 1801, to 926,000; in 1830, to 1,190,512; and in 1834 to 1,223,800. The duchy of Schleswig, at the beginning of 1803, contained 325,743 inhabitants, and, at the beginning of 1835, 430,258. In the same years, and at the same periods, the duchy of Holstein contained 278,341, and 332,866 respectively.

The Dane is of a strong, well-knit, muscular make; his features regular, eyes blue, and hair commonly light. 'The gift of the Dane,' says Rothe, a native writer, 'is strength, where others have inherited liberty. He is susceptible of high, strong, and enduring feelings, but he is not easily roused; he has more common sense than wit, and, being of a patient disposition, looks at every side of a question, and requires much time for deliberation.'

The population of Denmark is collected in 98 towns, 45 market-towns (all in the three duchies), and 4985 villages, besides isolated farms and dwellings. It was thus classified in the year 1834—the number assigned to each class includes children, servants, and others dependent on the principals—clergymen, schoolmasters, and other teachers, 25,549; civil officers and clerks in public offices, 30,018; scientific and literary men, artists, and students, 5,029; officers in the army and military departments, 3,783; naval officers, 937; under-officers and soldiers, 10,075; sailors in the navy, 6,036; seamen otherwise employed, 34,103; employed in agriculture, 598,558; manufacturers and handicraftsmen, 221,957; traders, 43,342; capitalists and persons living on their property, 47,568; day-labourers, 139,957; professors, 43,576; criminals, 1,470; persons whose occu-

pations are not described, 11,742: total, 1,223,800. This return applies to Denmark and the duchies of Schleswig and Holstein only; and it is estimated that 1,100,000 of the whole of their then population were more or less dependent upon agriculture for their subsistence. The proportion of births to living individuals is 1 in 32; and of deaths to living individuals 1 in 40. The proportion of marriages to the population in the 10 years ending in 1834 was 1 to 123. On an average the issue of each marriage was 2½ children. In the same year the town population consisted of 295,212, and the rural population of 1,234,983.

Denmark is pre-eminently an agricultural state. The most fertile parts are the islands of Laaland and Falster, and next to them Seeland and Fünen; but agriculture is not so skilfully or actively pursued in these parts as in Holstein and Lauenburg, particularly in the Northern and Southern Ditmarshes of Holstein on the Baltic coast, where the most perfect tillage in Denmark prevails. Jütland has the least productive soil of any part of the kingdom, a considerable portion of its western districts, as well as those of Schleswig and Holstein, from the Eyder to the Limmfjord, being wholly unavailable for agricultural purposes. The Danes, as agriculturists, are deficient in energy, intelligence, and thriftiness. Their backwardness in this respect arises from a variety of causes, of which the chief are, as Olufsen, one of their countrymen, remarks, that the cultivator is rarely proprietor of the soil, that he is overburdened with dues and services, that there is too great an extent of common lands, that his capital is too small, and that property is too much subdivided.

Denmark and the adjacent islands contain an area of about 21,472 square miles, or 13,742,080 acres. Of this area there have been applied to useful purposes about 16,266 square miles, or 10,410,240 acres; being nearly 76 in every 100 acres. This quantity is composed of about 8,633,600 acres of arable land; 604,800 of meadows; 470,400 of pastures, &c.; and 537,600 in woods and forests; besides about 107,520 of arable and meadow or pasture land, and 56,320 of woods, forests, &c., in the duchy of Lauenburg. The average yearly produce of the cultivated soil is estimated at 300,000 quarters of wheat, 1,400,000 of rye, 4,450,000 of oats, 2,000,000 of barley, 115,000 of buckwheat, 245,000 of peas and beans, 250,000 of rapeseed, 2,200,000 tons of potatoes, 2500 cwt. of hops, and 448,000 pounds of tobacco. It is stated by Nathanson that the yearly exports of this produce, on an average of ten years (1821 to 1830), were from 900,000 to 950,000 quarters; namely, wheat, 130,000 quarters; rye, 185,000; barley, 315,000; oats, 200,000; buckwheat, 17,000; peas and beans, 14,000; and rapeseed, 70,000; besides 20,000 quarters of malt and 16,500 of meal and flour. By a return laid before parliament, the average exports of corn for the four years 1831-1834 were—wheat, 103,302 quarters; rye, 100,829; barley, 366,969; and oats, 171,954. Of the grain exported, above four-sevenths, and of the rapeseed more than four-fifths, are from the Danish duchies. As a proof that agriculture, though comparatively backward, has made considerable advances, not only in the latter provinces, but in the northern parts and islands, it may be observed that Jütland and the islands did not produce sufficient grain for their own consumption in the last century, whereas they now afford a surplus of at least 50,000 quarters for foreign markets. Much flax and hemp is also raised, but little of superior quality, and in the whole scarcely enough for domestic purposes. Denmark produces the usual kinds of vegetables; but horticulture is not carried to any extent, excepting in the vicinity of the towns, especially Copenhagen, Altona, and Glückstadt. With respect to fruit, large crops of the commoner descriptions are produced; but attention is paid rather to quantity than quality. The value of landed property in Denmark Proper (Jütland and the islands) is estimated at 316,000,000 of banco dollars (about 25,675,000*l.*)

The rearing of horses and cattle is an object of great attention. The light Danish and heavy Holstein breeds of horses are equally valuable in their way, the one for cavalry purposes and the other for draught. The Jütland breed is similar in figure and extraction to the Holstein, but has not so fine a head. The king has two large studs at Friedrichsburg and Jägerpreiss; and numerous establishments of this kind are kept up by individuals, particularly in Fünen. The whole stock in Denmark and the duchies is estimated at 550,000; and the exportations, on a ten years'

average, are about 7600 annually. In 1831, as many as 12,350 were sent abroad. The rearing of horned cattle is on an extensive scale, chiefly with a view to the making of butter and cheese and salted beef. The stock of all ages is estimated at 1,607,000; and the number exported averages yearly about 23,800 oxen, 6800 cows, and 5760 calves. Of butter alone upwards of eleven millions of pounds' weight have been the annual average export of the last ten years. Cheese (about 9200 cwt. exported), lard, salt meat, hides, and skins are likewise exported in great quantities. Large flocks of sheep are kept: the best native breeds are the Eyderstedt and Frisian in Schleswig, and the Jütland race; but they are reared rather for the sake of their flesh and milk, from which last cheese is made, than for their wool. The stock is estimated at about 1,900,000, of which about 20,000 have been improved by crossing with the Merino breed. The quantity of wool annually obtained is said to be about 4,880,000 pounds' weight, and the quantity exported is about 1,080,000. Of swine, Denmark possesses three species, the best of which is the Jütland sort; their numbers are about 450,000; the annual consumption about 250,000; and the yearly export about 20,000. Poultry of all kinds are raised, particularly geese, of which about two millions are annually killed. Much honey and wax is made in Fünen, Falster, and Bornholm, and also from the bees on the heaths in the duchies of Schleswig and Holstein; but neither the one nor the other is adequate to the domestic consumption.

The fisheries form a very essential branch of national industry: the bays and inlets, and the mouths of the Danish rivers being well stocked with fish, afford abundant and profitable employment to the inhabitants in almost every part of the long line of coast. The fishing grounds of the Liimfiord, and indeed of the whole north-eastern coast of Jütland, are the most important with regard not only to the herring trade, but other descriptions of fish, such as mackerel, cod, salmon, eels, flat-fish, shell-fish, &c.: they employ upwards of 250 boats, and 1000 men belonging to the adjacent coast, besides a great number of vessels from other parts, among which are above 100 large barks, here called Quasen, which resort here from Seeland, Fünen, and Bornholm. The average annual produce of salted herrings in this quarter alone is from 40,000 to 50,000 tons, of which between 15,000 and 20,000 are exported; in some years, indeed, the catch has proved so abundant, that the export has amounted to 40,000. The herring fishery in the Great Belt gives occupation to more than 100 vessels. Oysters are in Holstein a crown monopoly, which is let for about 1200*l.* per annum. Seals are taken on the Jütland coast about Eyderstedt, and their fat is converted into oil. There is an association for the herring fishery at Altona, who are the proprietors of twenty or thirty vessels. The Danes also take an active part in the cod-fishery of the North Sea and the whale-fishery off the shores of Greenland.

The fine forests which once enriched the Danish soil have gone to decay from want of care and from wasteful consumption. This has especially been the case in Denmark Proper and the duchy of Schleswig; and Olufsen himself does not estimate their present area at more than about 840 square miles. One fourth of them is crown property. The woods stretch northward from the Schley, along the eastern coast of Jütland to the Liimfiord; there are long tracts of them also in the south-western parts of Fünen, from Børgense to Svenborg. The woods of Seeland, Falster, and Laaland are of low growth. The pine is the prevalent tree, intermixed with the beech, oak, and birch. Denmark is dependent for her supplies of timber on Norway, Prussia, Russia, and other countries, and the inhabitants are compelled, in many parts, from the positive absence of wood, to resort to any substitute, such as manure, straw, haulm, &c. for fuel. There is little inland game but what is found in the royal and other forests; but great numbers of wild waterfowl are killed on the islands along the Schleswig coasts and in other parts.

Denmark possesses no mines or metals whatever; nor any minerals of importance, except coals, freestone, and salt: the coal-pits in Bornholm have been abandoned, and there is but one saltwork, that at Oldesloe in Holstein, which yields about 5000 tons annually. The supply of salt is drawn from Portugal, Lüneburg, &c. Amber is collected on the Hitze, a sandbank on the western coast of Jütland; it is both of the white and deep yellow kinds. Pottery and porcelain earths are also obtained.

Peat is got wherever there are swamps, and every village in those parts has bog-land assigned for its supply.

In a country where agricultural pursuits create a greater demand for labour than what the population is competent to furnish, any great development of manufacturing industry cannot reasonably be looked for. In fact, out of a population of upwards of two millions, we are told that there are not above 85,000 hands engaged in large manufactures, and in mechanical employments altogether about 300,000. The Danish capital is the chief seat of manufacture, and we refer to the article COPENHAGEN for the details. Altona is next in importance: its principal productions are silk, woollen, and cotton goods, leather, soap, refined sugar, and tobacco. Lace is made on a very extensive scale in and about Tondern; and some is so fine as to be worth thirty or forty shillings a yard. There are large tobacco manufactures, but they are said not to produce more than one-eighth of the quantity consumed. The woollen manufactures, which are estimated to produce about 350,000 yards of coarse and middling cloths, are chiefly in Copenhagen, Fredericia, and other parts of Denmark Proper, and the cotton in the same capital, Altona, Roskilde, Christianfelde, and Hønerau. There are 24 paper mills in the kingdom, whose annual produce is about 1,200,000 reams; Randers is the principal seat of the glove manufacture; and Friedrichsværk, Lyngby, and Haraldskjaer, of the manufacture of ironwares, next to the metropolis. Linens are made at Kiong and Holsteinborg, and in most parts constitute the occasional employment of the cottagers for the purpose of supplying their own wants. Straw hats, sailcloth, glass, soap, leather, saltpetre, gunpowder, and arms, plated goods, china and earthenware, beer and spirits, thread, refined sugar, soda, and potashes, are among the productions of Danish industry. The brandy distilleries exceed 3000 in number; and there are upwards of 4000 hands employed in making wooden shoes in various parts of Jütland. The peasants' families make their own woollen clothing in general, which is composed of a coarse stuff termed wadmél, and indeed there are few articles of domestic use, whether utensils or for apparel, which are not made by their own hands.

There is probably no country in Europe better adapted or more favourably situated in many respects for commerce than Denmark. It is the key of the Baltic, and possesses peculiar advantages for a ready and cheap intercourse with all the maritime nations of Europe. Copenhagen is the central point of the Danish foreign trade, which has been greatly favoured by the neutral policy which the government has endeavoured to pursue during the last hundred years and more. Navigation, in which above 50,000 hands are employed, is a great source of profit to the country, for the Danes navigate their vessels on cheaper terms than many of their competitors, and are excellent mariners, on which account they are the carriers for other countries, particularly to the Mediterranean and Levant. This branch of commerce is on the increase: in 1825, Denmark had 3876 vessels of the total burthen of 118,393 tons; in 1829, 3691, burthen 128,084 tons; and at present their number is estimated at upwards of 3700, in burthen 143,800 tons. In the first three years of the present century the average arrivals of Danish and Norwegian ships in foreign ports were annually 3933, of the total burthen of 401,351 tons, of which the Norwegian constituted one half at least; in 1830, they had increased to 4029 of 236,650 tons burthen, for Denmark alone. This increase will appear the greater, when it is recollected that between the years 1807 and 1810, as many as 900 vessels were lost or captured, by which the trading ships of Denmark were in 1814 reduced to so small a number, that their united burthen did not exceed 74,520 tons. In 1831, the tonnage of the British vessels which arrived in the Danish ports was 16,519 (vessels 96); and in 1835, 22,249 (vessels 120). The trade between the mother country and the West and East India colonies is quite free; the busiest traffic is carried on with the island of St. Thomas; and the value of the native produce and manufactures annually exported to all parts is about 15,000,000 dollars or 2,340,000*l.* The trade with Norway, which takes much grain, tallow, soap, &c. from Denmark, employs 200 or 300 Danish ships, and that with Iceland, Greenland, and the Faeroe Islands is of some importance. In a preceding page we have given some account of the export of grain; among the other articles of exportation are butter, cheese, brandy (about 3800 pipes), salted and smoked meats (about 3,400,000*lbs.*), horned cattle (about 31,000 heads),

horses, skins and hides, whale and tram oils, eyder-down, woollens, fish, tallow, bristles, &c. Denmark, on the other hand, imports wines, salt, silk, wools, and cotton, cotton manufactures, timber, coals, colonial produce, brandies, and spirits, glass, flax and hemp, drugs, &c. to the extent of about 14,000,000 dollars, or 2,270,000*l.* yearly. The public trading associations consist of the Royal Asiatic Company, which has 10 vessels employed in the China and East India trade, and the privileged Baltic Company, which carries on an extensive trade with the Baltic ports: both of them are established in Copenhagen. There is a brisk intercourse by sea between the several ports. The chief places of trade are Copenhagen, Altona, Kiel, Koersøer, Helsingør, Odensee, Viborg, Randers, Flensburg, Schleswig, Aalborg, Rendsburg, Tondern, Aarhus, Glückstadt, Neustedt, and Itzehoe. At Copenhagen there are a Board of Internal Economy and Commerce, a National Bank, an Exchange and Loan Bank, and a Marine Insurance Company; and at Altona, an Exchange, Loan, and Discount Bank. By the royal decree of May, 1817, no individual can carry on trade who has not attained his majority and taken up his citizenship. Foreigners are allowed to make purchases in the wholesale way, but not to sell goods. None can become wholesale dealers in towns but such as are owners of vessels, or parts of vessels, to the extent of 26 tons at the least, and have deposited the requisite sum in the treasury. No clerk can be employed who is under 18 years of age. The Schleswig and Holstein canal has greatly facilitated the commercial intercourse between Denmark and the Baltic: in 1807, 1597 vessels passed through it; in 1814, 2060; in 1823, 2468; and in 1830, 2999.

Denmark is an absolute and hereditary monarchy, founded on three fundamental laws; the Act of Sovereignty of 1661, the King's Law (*Konge Lowen*) of 1665, solemnly ratified by the whole nation, and the Native Subjects' Law (*Indfottis retten*) of 1776. As duke of Holstein and Lauenburg, the king is a member of the German Confederation, holds the tenth rank in point of precedence, has three votes in the full assemblies of the diet, pays a yearly quota of 2000 florins (about 90*l.*) towards the expenses of the confederation, and furnishes a contingent of 3900 men to the tenth corps of the confederate army. The sovereign must be of the Augsburg confession of faith, and must uphold its ascendancy in his dominions. He attains his majority on reaching his fourteenth year: descendants in the male succeed to the crown in preference to those in the female line. The sovereign fixes the allowances to be made to the members of the royal family of his own free will: all legislative and administrative acts proceed from his own will and pleasure. The orders of knighthood are the order of the Elephant, instituted in 1458: the Danebrog order, founded in 1219, and now bestowed for eminent services, and the order 'De l'Union Parfaite,' founded by the consort of Christian VI. in 1732, and admitting both of male and female knights. The nobility consist of one duke, nineteen counts, and twelve barons. In Holstein and Schleswig there is an equestrian community of about twenty seignorial families, who enjoy the rents and profits of all the sequestered monastic estates, to the amount of several millions of dollars per annum, and exclude the remaining moiety of the noble landholders in these provinces from all participation in that revenue. By a decree of the 15th of May, 1834, the kingdom was divided into four electoral districts, each of which has at present its provincial assembly: these districts are the Danish Islands, which choose from sixty-six to seventy representatives; Jütland, from fifty-one to fifty-five; Schleswig, forty-four; and Holstein, forty-eight. The states of Lauenburg are of antient date: they consist of the nobility, hierarchy, and representatives of towns, but seldom meet in full assembly, their affairs being despatched by a deputation who hold annual councils under the presidency of a marshal. The four provincial assemblies must be called together at least once in two years: their consent is necessary to all alterations in laws affecting persons or properties, public imposts, or requisitions for the national service; and they are allowed to propose laws for the sovereign's adoption, and to lodge complaints against any of the public authorities.

The privy council is, by the rescript of May, 1814, the highest board in domestic affairs: it is composed of the king, as president, a vice-president, and six members. The ministry consists of a minister for the land revenues, &c., for taxes and trade, for foreign affairs, for justice and police,

in Denmark Proper, for the same departments in Schleswig and Holstein, for the war department, and for naval affairs. The supreme court of justice is in Copenhagen. There is a governor for Schleswig and Holstein; and the West Indian Islands, the African possessions, and the East Indian settlements, have each of them a governor also. A Land-vogt, or lieutenant, governs the Faeroe Islands, and a Stifts-amtmann, or high bailiff, is at the head of the public authorities in Iceland.

The Danish Budget, showing the probable Receipt and Expenditure of the public Income of the kingdom of Denmark, for the year 1835:—

INCOME.

	Amount for Denmark Proper.	Amount for Schleswig and Holstein.	Total Amount.
I. Ordinary Revenues and Receipts.	Sterling.	Sterling.	Sterling.
1. Land Tax	£ 224,666	£ 136,445	£ 361,111
2. House Tax	35,777	14,333	50,110
3. Customs and Excise	311,111	79,111	390,222
4. Tax on Rank, and Salaries of Civil Officers	5,555	44,888	50,443
5. Stamps	29,111	15,000	44,111
6. Tax on Property inherited or transferred	11,888	10,333	22,221
7. Fees of Justice Courts and other Public Offices	18,000	3,666	21,666
8. Woods and Forests, and other Crown Lands	17,110	148,445	165,555
9. Lottery	28,888	17,223	46,111
10. Miscellaneous	6,227	1,333	7,560
	£ 688,333	£ 470,777	£ 1,159,110
II. Other Receipts.			
1. Surplus of Revenues derived from the Duchy of Lauenburg			£ 21,112
2. Interest on Property belonging to the Crown			48,888
3. Monies received on account of Property disposed of			114,444
4. Revenues of the West India Islands			5,555
5. Proceeds of the Sound Toll			200,335
Total of probable Receipts			£ 1,549,444

EXPENDITURE.

	Sterling.	Sterling.
I. The Royal Establishment		£ 130,441
II. Public Departments		154,556
III. The Army		294,666
IV. The Navy		134,777
V. The Colonies		15,555
VI. Pensions and Allowances		60,888
VII. Public Works		57,110
VIII. Industry and Trade		6,333
IX. Arts and Sciences.		
For the University of Kiel, including Miscel- laneous Expenses for the Promotion of Arts and Science	£ 20,222	27,444
Travelling Expenses of Young Artists and Literary Men	1,666	
Expense of the Theatre at Copenhagen	5,556	
X. Charitable Institutions and Donations		21,221
XI. Miscellaneous		44,788
XII. Public Debt.		
Interest upon the Public Debt	530,555	673,332
Payment to the Commissioners of the Sinking Fund	106,777	
Total of probable Expenditure		£ 1,585,111

Income in 1835 £ 1,549,444
Expenditure 1,585,111

Deficiency £ 35,667

The Lutheran is the predominant religion, but every other is tolerated. The affairs of the national church are under the superintendence of the eight bishops of Seeland, Laaland, Fünen, Ribe, Aarhus, Viborg, Als, and Aalborg, a general-superintendent, sixty-two provosts, and 1488 ministers. The bishoprics are in the gift of the crown. A decree of the 5th December, 1806, attached a provost to every district (*amt*), who is appointed by the sovereign, and relieves the bishop from certain duties, particularly those relating to the supervision of scholastic institutions. The ecclesiastical concerns of the Faeroe Islands are conducted by a provost and seven ministers; those of Iceland by a bishop, resident at Skalholt, and 182 clergymen; those of the duchy of Schleswig by eleven general superintendents, who have each of them a certain number of provostships under them, amounting to 165 in all, besides sixty-eight parishes; those of Holstein by thirteen superintendents under whom are 135 provostships and five parishes. There are twelve religious communities in Denmark Proper and the duchies; a missionary college at Copenhagen, called the 'Collegium de cursu evangelii promovendo,' founded in

1714, and a seminary for approved candidates in divinity in the same city. Out of a population of 2,040,000 souls there are about 1300 Reformed Lutherans, 2100 Roman Catholics, 900 Mennonites, 1500 Herrnhuthers, and 1700 Jews; the remainder are Lutherans. The number of parishes is 1907.

Much has been done for the education of all classes in Denmark. There are thirteen seminaries for educating teachers, upwards of 2500 primary schools, and 2000 others on the Lancasterian plan; thirty gymnasia or grammar-schools, of which eighteen are in Denmark Proper, four in Schleswig, six in Holstein, one in Lauenburg, and one in Iceland; and two universities, one in Copenhagen, and the other in Kiel; the first founded in 1479, and attended by about 600 students, and the other, founded in 1665, and attended by about 300. (For the Schools for the Deaf and Dumb, see that article, vol. viii., p. 335.) Among the public libraries are three in Copenhagen and one in Kiel. The designations of the eleven societies for scientific and national purposes which are established in Denmark are given under the head of COPENHAGEN. The number of new publications varies from 200 to 250 annually; but the number of periodical journals, &c., which amounts to between seventy and eighty, is large indeed, when compared with the population. No work which does not contain more than twenty-four pages can be published without the previous sanction of the director of police; and any offensive reflections or libels upon foreign potentates, whether original or extracted from other publications, are punishable as misdemeanours. In Iceland there prevails so ardent a thirst for knowledge, that manuscript copies supply the want of printed books, and there is scarcely one in a hundred individuals, above the ages of 12 or 14, who cannot read and write.

The numerical strength of the Danish army does not exceed 6000 men at present, independently of the troops employed in the colonies; but on the peace footing it nominally consists of—the engineers, nineteen officers and thirteen privates; the artillery, 4498 officers and privates; the cavalry, 3302 officers and privates; and the infantry, 31,026 officers and privates; besides a corps of 110 cadets, and a rocket-corps, 132, the total numbers being 39,099. A sufficient number of officers and others always remain at the disposal of the crown to call a force of 25,000 men at any time into active service. The heads of the army in 1836 consisted of a field-marshal, two generals, three lieutenant-generals, twelve major-generals, and seven brevet major-generals, together with an adjutant-general and a quartermaster-general, &c. Every soldier's engagement is for eight years, of which he is not at present required to pass more than two in active service. The militia, when called out, musters 59,000 rank and file.

On the 1st of January, 1836, the navy was composed of seven ships of the line, mounting 544 guns; eight frigates, 350 guns; and five sloops, five brigs, three schooners, and three cutters, mounting 200 guns: in all thirty-one vessels and 1094 guns. To these must be added fifty-six gun-boats and six bomb-vessels, &c. The chief officers consisted of one admiral, two vice-admirals, two rear-admirals, six commanders, eleven lieutenant-commanders, two captains, twenty-five lieutenant-captains, forty-one first-lieutenants, and thirty-three second-lieutenants.

The fortresses and fortified ports of Denmark are Copenhagen, Cronburg Castle, Korsøer, Fredericia, Friedrichsort, Friedrichshaven, Rendsburg, Christiansoe near Bornholm, Nyborg, and Glückstadt. The chief military and naval establishments are the Cadet Academy, Copenhagen; the Arsenal and Archive of Charts, in the same city; a cannon and ball foundry at Friedrichsværk; an invalid hospital at Eckernförde; and arsenals at Rendsburg and Randers.

History.—The oldest history of Denmark is pure tradition, derived from the suspicious source of the Icelandic Legends or Saga. The first fact of which we can speak is that the Cimbri, a branch of the Normans or Scandinavians, were the earliest known inhabitants of the peninsula of Jütland and Schleswig, which was thence called The Cimbrian Chersonesus. They first became known to the Romans from their taking part with the Teutones, about 100 years before the Christian æra, in the invasion of Gaul and Italy, in the times of Marius. About A.D. 250, the Goths overran the Scandinavian territories under Odin or Wodun, and imposed rulers of their own on Sweden, Denmark, and Norway. Skiold, Odin's son, is the first name which has descended to us as sovereign of Denmark; but we possess no record of his time beyond numerous legendary frag-

ments. Denmark appears however to have been divided into a variety of petty states, of which Skiold's descendants assumed the lordship for many centuries, and to have been inhabited by a warlike race of men, whose principal occupation was piracy. The Normans, or Angles, under which designation the Swede and Norwegian as well as the Dane were included, during the eighth and ninth centuries, established their dominion in parts of England, which they distracted by their inroads until the middle of the eleventh century: they also made themselves masters of Normandy under Rollo, colonised the Orkneys and Hebrides, the Isle of Man, Iceland, and part of Ireland, and pushed their settlements as far south as Spain, Italy, and Sicily. The first Danish monarch with respect to whom we are enabled to speak with certainty was Gorm, or Worm, the Old, a Skioldinger, who brought Jütland under his sway in 863, and succeeded between that date and the year 900 in uniting every state in Denmark to his dominion. His son, Harold II. the Blue-Tooth, introduced Christianity about the year 972. In 1000, Sven, his grandson, subjugated part of Norway, and in 1014 the greater part of England, where he soon after died; in 1016, his grandson Knud the Second, or Canute the Great, possessed himself of the whole of England and part of Scotland; and in 1030, of the remainder of Norway. To this monarch Denmark was indebted for her greatness, laws, and internal organization, and the establishment of Christianity as the religion of the country. His successors, however, were not endowed with capacity enough to preserve his dominion in its integrity: England threw off their yoke in 1034, and Norway two years afterwards. A new dynasty out of the female line of Canute's descendants mounted the throne in 1047, in the person of Sven Magnus Estritson the Third, and held the sceptre for four hundred years afterwards; but the feudal system erected by Sven and Canute stripped the sovereign of his authority, rendered the Danish king dependent upon the voice of the prelates and nobles, levelled the peasant to the condition of a serf, reduced agriculture to the lowest ebb, and surrendered commerce into the hands of the German Hanse Towns. The sovereigns were forced, by the assembly called the Handfaestningar, to recognise the states of the kingdom as their own electors, and to consent to the controul of a council. The male descendants of Magnus Sven became extinct with Waldemar the Third in 1375; and Olaf the Fourth, of the female line, Waldemar's grandson, dying in 1387, his mother, Margaretta, styled the Northern Semiramis, ascended the throne of Denmark. She acquired Norway by inheritance, and having subdued Sweden by force of arms, united the three northern kingdoms under one crown by the Calmar union in 1397. The Swedes, however, could never be brought to endure this league, and after a long series of contests, ultimately renounced the union in 1523. These contests undermined the prosperity of the Danish monarchy no less than the perpetual broils between the sovereign and his nobles on the one hand, and the nobility and clergy on the other; the population decreased greatly, and the adjacent seas swarmed with Danish pirates, while trade and navigation dwindled to insignificance. Margaretta's line having forfeited the throne in 1439, and Erick the Seventh having been deposed, the Danish States elected Christian Count of Oldenburg king. Christian founded the university of Copenhagen in 1478. The sway of his descendants was however but of brief duration, for his grandson Christian the Second, surnamed 'the Wicked,' having become obnoxious to all parties, the crown was transferred to his uncle Frederic the First, duke of Schleswig and Holstein, who received the crown of Denmark and Norway in 1523. This monarch was the mere slave of the aristocracy, who established abject servitude among the labouring classes as part of the law of the land. His son Christian the Third united the duchies of Schleswig and Holstein in perpetuity to the crown of Denmark in 1533, and brought the turbulent Norwegians to recognise the Danish kings as their sovereigns 'for ever.' In his reign the Reformation was established throughout the united kingdoms, and a code of laws, entitled the 'Recess of Kolding,' was promulgated. The struggles arising out of his partition of the greater part of Schleswig and Holstein between his brothers, became a source of much subsequent mischief to Denmark, and was not terminated until 1773, when the alienated territory was recovered by the cession of Oldenburg and Delmenhorst to its then possessor, the grand-duke of Russia.

The wars which his son Christian the Fourth waged with Sweden entailed so many disasters upon him, that he was compelled, by the treaty of Brocmsebroo, in 1645, to cede to Sweden the provinces of Jemteland and Herjedalen, together with the islands of Gottland and Oesel. His son and successor, Frederic the Third, renewed the hostilities with Sweden, whose sovereign, Charles Gustavus, invaded and overran his dominions, and at length wrested from him, by the terms of the treaty of Copenhagen in 1660, the extensive districts of Schonen, Halland, Blekingen, and Båhus, in Sweden. In the same year the three estates of the realm acknowledged Frederic and his successors as absolute sovereigns of Denmark, in solemn diet at Copenhagen; and they confirmed the surrender of their rights by presenting him with the 'Arfve-Enevolds-Regierungs-Akt.' This gave occasion to the promulgation of his 'Konge-Lov,' in 1665; the fundamental law of settlement which prevails in Denmark at the present day. He was succeeded by his son, Christian the Fifth, who established the Danish West India Company in 1671, acquired the islands of St. Thomas, St. Croix, and St. John, and founded a settlement at Tranquebar. War between Denmark and Sweden was rekindled by Frederic the Fourth, his son, and was brought to a successful close by the peace of Friedrichsburg in 1720, in which Sweden ceded the right of receiving the Sound dues to the Danes, and the long-disputed claim of Denmark to the sovereignty of Schleswig was fully recognised. The subsequent hundred years were a period of continued tranquillity, during which the state rose, and enjoyed prosperity: the happiest fruits of this interval of peace were, the abolition of servitude among the peasantry, begun by Christian the Seventh in 1767, the extinction of the negro slave trade, and the establishment of greater liberty of the press. During the wars of the French Revolution, Denmark observed a strict neutrality; but in contesting the right of search as to her mercantile shipping, insisted upon by England, which led her into a defensive alliance with Russia, Prussia, and Sweden, she brought upon herself the loss of her East and West India colonies, and suffered severely in the naval fight off Copenhagen in 1801. The treaty which ensued restored those colonies to her. The peace of Tilsit, in 1807, in which there were secret articles stipulating that the whole Danish navy should be delivered over to the French emperor, occasioned however a fresh rupture with England, which commenced with the appearance of a formidable force under Earl Cathcart and Lord Gambier on the coast of Seeland, and was carried to open hostilities upon the refusal of the Danish government to surrender their fleet, consisting of 15 ships of the line, 14 frigates, and 3 brigs, as well as their timber and the naval stores then in the yards and arsenal of Copenhagen. Upon this refusal, Lord Gambier bombarded the Danish metropolis, from the 2nd to the 5th of September, forced it to capitulate after a considerable part of the town had been burnt, and carried away the fleet to England. In November following a formal declaration of war was issued by the English government, and Denmark, whom the outrage at Copenhagen had effectually thrown into the arms of France, was again stripped of her colonial possessions, and not only lost the islands of Anholt and Heligoland, but the whole of her foreign commerce. Even after the destruction of Napoleon's armies in Russia, and in spite of the efforts of the allied powers in 1813, she could not be induced to renounce her alliance with France, and the summons to surrender Norway to Sweden impelled her still more strongly to persist in that alliance. The consequence was that the Crown Prince of Sweden entered Holstein and Schleswig, and by his successful progress terrified Frederic the Sixth into signing the treaty of Kiel on the 14th of January, 1814. In virtue of its terms, Denmark accepted Pomerania in exchange for Norway. This province was in 1815 ceded by her to Prussia, in consideration of her receiving the duchy of Lauenburg and a large sum of money. In making peace with England, she recovered her colonial dominions, but with the loss of her fleet and the island of Heligoland.

DENNIS, JOHN, was the son of a saddler of London, where he was born in 1657. Having been put to school at Harrow, he was sent thence in 1675 to Caius College, Cambridge. In 1679 he removed to Trinity Hall, in the same university, and in 1683 took his degree of A.M. There appears to be no foundation for the story told in Baker's 'Biographia Dramatica,' that he was expelled from college

for attempting to stab a person in the dark. On leaving the university he spent some time in travelling through France and Italy. Returning home from the continent, full of dislike to the manners of the people, and especially to the modes of government he had seen there, and finding himself in possession of a small fortune, the bequest of an uncle, he set up for a flaming whig, and formed connexions with several of the leading political and literary characters of that party. As a man of letters, however, he did not confine his acquaintance within the limits of his political partialities; Dryden and Wycherley, for instance, as well as Halifax and Congreve, are enumerated among his friends. In the idle and expensive life which he now led he soon dissipated what property he had, and for the rest of his life he was obliged to depend for subsistence upon his pen, and the still more precarious resource of private patronage. No experience however seems to have cured his improvidence. In his difficulties the duke of Marlborough procured for him the place of a waiter at the Custom House, a sinecure worth 120*l.* a year; but he was not long in selling this appointment, and it was only the kind interference of lord Halifax that induced him to reserve out of it a small annuity for a certain term of years. This term he was unfortunate enough to outlive, and, to add to his miseries, he became blind in his last days, so that he was in the end reduced to solicit the charity of the public by having a play acted for his benefit, which some of his old friends, and some also whom he had made his enemies, interested themselves in getting up. Dennis died in 1734. Throughout his life the violence and suspiciousness of his temper had at times approached to insanity, and were the constant curse of his unhappy existence, making him at once miserable and ridiculous. Owing to this disease he quarrelled with everybody, and rarely made a friend or an acquaintance in whom his distempered vision did not soon discover an enemy in disguise. Yet Dennis wanted neither talents nor acquirements. Many of his literary productions show much acuteness and good sense, as well as considerable learning. He began to publish occasional pieces in verse, mostly of a satirical cast, about 1690, and from that time till near his death his name was constantly before the public as a small poet, a political and critical pamphleteer, and a writer for the theatres. His poems and plays were sufficiently worthless; but one or two of the latter obtained some notoriety chiefly from the fuel they administered to certain popular prejudices that happened to rage at the time. His 'Liberty Asserted,' in particular, was acted with great applause in the Lincoln's Inn Fields theatre in 1704, in consequence of the violent strain of its Anti-Gallicism, a sentiment with which the audience, in the excitement of the war with France, was then peculiarly disposed to sympathise. Connected with this play are the two well-known stories about Dennis, during the negotiations that preceded the peace of Utrecht, going to the duke of Marlborough and asking his Grace to get an article inserted in the treaty to protect his person from the French king; and about his afterwards running away from the house of a friend with whom he was staying on the Sussex coast, because he thought that a vessel he saw approaching was coming to seize him. Another of his dramatic attempts, his 'Appius and Virginia,' acted and damned at Drury-lane in 1709, is famous for the new kind of thunder introduced in it, and which the author, when a few nights after he found the players making use of the contrivance in Macbeth, rose in the pit and claimed with an oath as his thunder. Dennis's thunder is said to be that still used at the theatres.

Among the ablest of his critical disquisitions were his attacks upon Addison's 'Cato,' and Pope's 'Essay on Man.' Addison had been among the number of his friends, but Dennis supposing that something in the second and third numbers of the 'Spectator' was intended as an offensive allusion to him, took the opportunity of avenging himself when 'Cato' appeared. Much of his criticism nevertheless has generally been deemed by no means the product of mere spite. It was upon this occasion that Pope, in conjunction with Swift, wrote 'The Narrative of Dr. Robert Norris, concerning the strange and deplorable Frenzy of Mr. John Dennis, an Officer in the Custom House.' Pope also stuck Dennis in his 'Essay on Criticism,' and afterwards gibbeted him much more conspicuously in the 'Dunciad.' The life of Dennis has been written with prodigious expansion by Dr. Kippis in the 'Biographia Britannica,' his article extending

to fourteen long folio pages. He has also furnished the subject of an amusing paper in Mr. D'Israeli's 'Calamities of Authors,' entitled 'Influence of a Bad Temper in Criticism.'

DENOMINATOR, the number of parts into which a unit is divided in any fraction; thus, in 7-10ths of a unit, 10 is the denominator. [**FRACTION**.]

DENS CANIS. [**ERYTHONIUM**.]

DENSITY. This term is absolutely of the same practical meaning as its measure, **SPECIFIC GRAVITY**, implying that relation of one mass of matter to another, which is suggested by our knowing that a given bulk of the first weighs more than the same of the second. The term has no absolute meaning: gold is more dense than air, but neither is absolutely dense, nor can we assign any meaning to the latter term. It were perhaps to be wished that the shorter term, density, should be employed instead of the longer one, specific gravity; but as custom has referred to the latter term all mathematical considerations connected with the former, we do not here pursue the subject further. [**SPECIFIC GRAVITY**.]

DENTALIUM, a genus of testaceous mollusks, whose place in the animal series was first satisfactorily determined by Mr. G. P. Deshayes. Rondelet considered the Dentalia as marine shell-worms (*vermisseaux de mer*), though he noticed them as worthy of particular attention; Lister introduced them at the end of the limpets (*Patellæ*); Lang followed in nearly the same steps, separating, after the *Patellæ* a section wherein he arranged, together with the Dentalia, all the calcareous tubes of Annelids then known. Breyne placed his genus *Tubulus*, containing the Dentalia, &c., at the head of his *Monothalamous shells*, the first of the two grand orders, the *Monothalamous* and the *Polythalamous*, into which he divided the testaceans. In this position Dentalium was separated from the *Patellæ* by all the other univalve shells comprised in the *Cochlidia*, as well as by the *Polythalamous* series; in short, by the entire interval of the univalve testaceans, Breyne, as M. Deshayes observes, having probably considered the *Patellæ* as the passage from the univalves to the bivalves; for he places them immediately before the latter. Tournefort gave the *Patellæ* a position at the head of the univalve shells, and at the end, before the bivalves, he placed the *Dentalia*, *Entalia*, and the other marine testaceous tubes. D'Argenville, in his 'Zoomorphose,' appears to be the first who attempted to give any notion at all approaching to reality of the animal, the result of a note and drawing which had been sent to him from India. Though the materials were too incomplete to furnish secure data for fixing its position, they gave information which former authors had not enjoyed, and there was certainly enough to prevent D'Argenville from placing it in the heterogeneous third division of his system, denominated by him the Multivalves. Linnæus arranged it immediately after *Patella*, and before *Serpula*, stating the animal to be a *Terebella*, and the shell to be univalve, tubular, straight (*recta*), monothalamous, and pervious at each extremity. Bruguière gave it nearly the same position: but if both these zoologists were right in making Dentalium follow *Patella*, they were as far wrong in placing it by the side of *Serpula*, *Teredo*, *Sabella*, and above all, *Aspergillum*. Lamarck, in his 'Système des Animaux sans Vertèbres,' (1801,) arranged Dentalium with *Terebella*, and other genera analogous in appearance. In the 'Philosophie Zoologique' he separated the class of worms of the *Système* into two other classes, and formed the 'annelids,' with the section of external worms (*vers extérieurs*). He elevated, observes M. Deshayes, this division sufficiently in the series of *Invertebrata*, the presence of a heart and a circulation making it approximate to the mollusks; whilst the 'worms,' very inferior in organization, remained between the soft *Radiata* and the *Insects*. In this new class, adds M. Deshayes, we find the Dentalia in the same section with *Serpula*, *Spirorbis*, and *Siliquaria*. This arrangement was not altered in 'L'Extrait du Cours,' published in 1811. But, in the great work of the 'Animaux sans Vertèbres,' Lamarck, assisted by the labours of Savigny, and deceived, moreover, by the communications of M. Fleuriau de Bellevue, considered *Dentalium* as approximated to *Clymene*, and placed it in the family of *Maldanians* of M. Savigny. Systematic authors, generally, not knowing more than Lamarck did, that knowledge being confined to the tube, followed Lamarck's opinion. Cuvier, in the first edition, placed it among the *Annélides Tubicoles*, between *Aspergillum* (*Penicillus*, Lam.) and *Siliquaria*.

Savigny, in his 'Système des Annélides,' gave a summary description of the animal, but it was too incomplete to decide the question finally, though sufficient to overthrow the observations of M. Fleuriau de Bellevue. The *Dentalium Entalis*, which was sent to Savigny by our countryman Leach, gave sufficient information to that celebrated zoologist to enable him to say that the animal had no trace of rings, that it had no hairs (*soies*) on the lateral parts of the body, that it was essentially muscular, and that it could no longer remain among the *Chaetopods*.

Dentalium Entalis was the species on which M. Deshayes made his observations; and in a very interesting and elaborate paper read before the Society of Natural History of Paris, on the 18th of March, 1825, he gave the facts which led him to the conclusion stated at the commencement of this article. The following is a summary of his description: but we must premise that M. Deshayes's specimens were forwarded to him in spirit, and were, consequently, a good deal contracted.

External Parts. Animal conical and elongated, like the shelly investing tube; (*dorsal surface* corresponding with the convexity of the shell; *ventral surface* corresponding with the concavity;) smooth and truncated obliquely at the anterior end, the centre of the truncation with a small pyramidal process, which is the extremity of the foot. The posterior parts are less muscular, and the termination is usually a funnel-shaped expansion, variously developed in different individuals; for in some it is firm and well developed, and in others it is scarcely perceptible. This expansion is separated from the rest of the body by a strongly defined contraction. There is a muscular ring, broader on the ventral than on the dorsal surface, above this contraction, and by that ring the animal is attached to the shell, which on its inner surface presents, at about one-fifth of its length from the posterior extremity, a corresponding impression in the shape of a horseshoe, the interrupted portion being on the concave side. On the dorsal surface a small elevation is perceptible, at about one-third of its length from the anterior end, indicating the place of the head. The whole extent below this is occupied by two muscles on each side, distinctly observable through the abdominal parietes. These muscles are symmetrical, flattened, and directed obliquely from the sides of the foot towards the dorsal surface and the posterior extremity of the animal, giving rise to, and becoming commingled with, the muscle of attachment. On the abdominal surface, likewise, there are on each side, at about one-third of its length from the anterior end, two symmetrical organs deeply jagged, and of a dark brown colour: these form the liver. Below this point, nearly the whole of the abdomen is visible through its transparent parietes filled by granulations contained in the very large ovary, and by the straight descending intestine which terminates at the expanded extremity in a mesial vent. The whole of the anterior part of the animal is invested by a fine membrane, which is fixed posteriorly to the origin of the foot, and is free in front, where its circumference is thickened. It is perforated in its centre, and M. Deshayes considers this to be the mantle. The thickened portion is produced by a circular sphincter, which, when contracted, wrinkles the skin, closely embraces in its opening the extremity of the foot, and thus cuts off any external communication. M. D'Orbigny, jun., who furnished a drawing of the living animal in an expanded state, makes the dilated lobes of the foot resemble a flower, whose undulated and small corolla supports in its centre a pistil thickened towards the middle, and pointed at its free end.

On slitting the mantle down the middle of its dorsal surface, separating it from its insertion to the right and left, and turning it downwards and to the right, the foot, the head, and the branchiæ appear.

The *foot* is elongated, subcylindrical, slightly conical, and flattened from above downwards, fleshy throughout, and situated at the interior and anterior part of the head, having its upper and under surfaces slightly grooved in the middle. The anterior extremity is largest, and its centre is occupied by a sort of conical nipple, broader at its base, being there partly covered by two small notched lateral lobes, the notches corresponding with the grooves of the foot. The posterior extremity has a bifurcated appearance, owing to the attachment there of the retractor muscles; its middle portion projects a little into the abdominal cavity, giving support to the stomach and the other principal viscera.

Organs of Digestion. The head consists only of a mouth, and is situated superiorly at the hinder extremity of the foot. It is bell-shaped, and flattened from before backwards. Two black points on its sides might be mistaken for eyes, but these are the *jaws* situated within the mouth, and visible through the thin substance of which it is composed: they are spherical, horny, rough on their outer surface, cleft in the middle, and bearing a considerable resemblance to a small bivalve shell. There are two *lips* deeply cleft at the margin, or, more properly speaking, furnished each of them with three pair of labial tentacles, those of the posterior lip, the middle pair especially, being much larger than those of the anterior. There is a naked space in the centre of the anterior lip indicating the aperture of the mouth, which is contracted into a short fleshy *œsophagus*, terminating rapidly in a thick pear-shaped *stomach*, supported by and closely adhering to the extremity of the foot, and containing within, near the cardiac opening, a rather complicated tooth-like apparatus. By a distinct vessel from each of the symmetrical lobes of the liver its secretion is poured into the stomach, which terminates below in a slender, transparent, straight, mesial intestine opening, as before observed, at the dilated posterior extremity.

Organs of Generation. Imperfectly known. No male organ discovered. The external opening of the large ovary not yet detected.

Circulating System. Heart symmetrical, situated above the stomach, and contained in a pear-shaped pericardium. A vascular trunk issues from the anterior extremity of this sac, passes in the direction of the neck, and divides into two large branches, one being distributed to each of the *branchiæ*.

Respiratory System. *Branchiæ* two, symmetrically situated on the lateral and posterior parts of the neck, and supported on a divided pedicle or branchiferous membrane, formed of many very fine, soft, flexible, tentacular filaments with club-shaped terminations, and appearing from their position to be equally adapted for directing nourishment towards the mouth, and for fulfilling their important office of aerating the blood.

Nervous System. Apparently ganglionic; the cerebral ganglion, the only one yet detected, is small, quadrilateral, considerably elongated, and placed longitudinally on the middle of the posterior surface of the head. Two very minute filaments issue from its inferior angles and pass to the *œsophagus*; they have not been traced beyond it.

M. de Blainville (*Malacologie*, 1825) agrees with M. Deshayes in the conclusion to which the latter came, viz. that *Dentalium* is a true mollusk, and he makes it the type of his first order *Cirrhobranchiata*, of his first section of his third subclass, *Paracephalophora Hermaphrodita*, placing it next to *Patella*. M. Rang (1829) follows De Blainville in referring it to his order *Cirrhobranchiata*, of which Rang makes it the only family, as does De Blainville, and he gives it a situation between *Fissurella* and *Patella*. Cuvier, in the last edition of the *Règne Animal* (1830), still retains *Dentalium* among the *Annelids*, placing it immediately after *Siphostoma* of Otto; but he adds, that the recent observations of Savigny, and above all those of Deshayes, render such a classification very doubtful. The animal, he observes, does not appear to possess any sensible articulation, nor any lateral hairs (*soies*), but it has anteriorly (en avant) a membranous tube, in the interior of which is a sort of foot, or fleshy and conical operculum, which closes its orifice. On the base of this foot, he adds, is a small and flattened head, and on the nape are to be seen the plumose *branchiæ*. If, he continues, the operculum recalls to mind the foot of the *Vermeti* and *Siliquariæ*, which have already been transferred to the class of mollusks, the *branchiæ* remind us of *Amphitrite* and *Terebellum*; and he concludes by remarking that ulterior observations on their anatomy, and principally on their nervous and vascular systems, will resolve this problem. Mr. Gray, who has compared the description of the animal given by M. Deshayes with specimens in the British Museum, is, he informs us, satisfied with the correctness of that description, and he considers that the most natural situation of *Dentalium* is nearest the *Fissurellæ*, but still far from them. The apices of the British species, he observes, often appear to be either broken off, or to have fallen off of themselves, like the tips of decollated shells; and he adds, that when the tip is broken, the animal forms a slight tube within, which is more or less

produced beyond the tip; and that the late Dr. Turton described a specimen in this state as a species under the name of *Dentalium labiatum*. Mr. Gray thinks that there is only one species found on our coasts, the other so-called species being mere varieties depending either on the worn or broken state of the specimens. In his '*Spicilegium Zoologicum*' he has described a *Siphunculus* which inhabits these shells, and which, he believes, has been considered by some authors to be the real inhabitant of the shell.

1. Shell of *Dentalium Entalis*, nat. size. 2. Shell magnified, broken longitudinally, showing the animal in a contracted state; *a*, the posterior extremity prolonging itself into a small accidental tube. 3. Magnified, representing the animal at the moment of its advancing out of the shell; *a*, *b*, the foot, the lobes of which are developed in the form of a corolla; *c*, a part of the collar. 4. The animal magnified, abdominal aspect; *a*, extremity of the foot; *b*, the collar; *c*, *c*, the mantle; *d*, *d*, the liver; *e*, the intestine; *f*, the ovary; *g*, the muscle of insertion; *j*, *h*, the *pavillon* and its neck; *i*, the vent. 5. Magnified, dorsal aspect; *a*, extremity of the foot; *b*, the collar; *c*, *c*, the mantle; *d*, slight projection produced by the head and the *branchiæ*; *e*, *e*, internal retractile muscles; *f*, *f*, external retractile muscle; *g*, neck of the *pavillon*; *h*, the *pavillon*. 6. Magnified. The mantle has been slit in the dorsal and mesial line, detached in part from its posterior insertion, and turned aside showing, *a*, the extremity of the foot which closes the aperture *j*, of the collar *l*, *m*, of the mantle *n*, *o*, *p*; *b*, *b*, lobes of the foot; *c*, the foot itself, presenting a depression or channel running its whole length; *d*, the head; *e*, the cerebral ganglion; *f*, *f*, the two buccal jaws; *g*, *g*, the pedicles or branchiferous membranes; *h*, *h*, *i*, *i*, the *branchiæ*; *p*, *p*, *q*, *q*, the retractor muscles; *s*, the muscle of insertion; *t*, the neck of the *pavillon*. 7. fig. 4 nat. size. 8. fig. 6. nat. size. (Deshayes.)

Generic character. *Animal* (see above.) *Shell* regular, symmetrical, in form of a very elongated cone truncated at the summit, slightly curved, open at each extremity by a rounded orifice.

Geographical Distribution, very much extended: few seas are without some of the genus, which varies much in size.

They are found sometimes in deep water, frequently near the shore.

The species are numerous. M. Deshayes in the monograph which follows the anatomical part of his memoir above abridged, gives forty-two recent and fossil. Mr. G. B. Sowerby in his 'Observations on Mr. Deshayes's Monograph' (Zool. Journ. vol. iv. p. 195), proposes some corrections with regard to several of the species given in the monograph, and adds two to those recorded by Deshayes, and in the Proceedings of the Zoological Society (1832) describes four new species brought home from America by Mr. Cuming.

M. Deshayes separates his forty-two species into four groups, one of which is rejected by M. Rang, because it is occupied by *Dentalium coarctatum* of Lamarck, which M. Rang regards as belonging to his (M. Rang's) subgenus *Cresis* belonging to the genus *Cleodora*.

1.

Shell not slit at its posterior extremity.

a. Longitudinal striæ.

Example, *Dentalium Elephantinum*.

b. No longitudinal striæ.

Example. *Dentalium Entalis*.

2.

Shell slit at its posterior extremity.

a. Longitudinal striæ.

Example. *Dentalium striatum*.

b. No longitudinal striæ.

Example. *Dentalium eburneum*.

3.

Shell having a marginal rim; not slit at its posterior extremity.

Example. *Dentalium strangulatum*.

FOSSIL DENTALIA.

'Of fossil species,' says Mr. G. B. Sowerby, 'there are many, particularly in the marine beds of the tertiary formations; the London clay and the Calcaire Grossier swarm with several sorts not easily distinguishable from the recent species, among which we may particularly remark the fossil species from Piacenza, which so nearly resembles *D. elephantinum* that Brocchi has not hesitated to refer it to that species, and the *eburneum* of Lamarck, which he says inhabits India, and is found fossil at Grignon. Deshayes, in his tables gives the number of living species as twenty-three, of the fossil (tertiary) thirty-four, and the following, *Dentalia elephantinum*, *dentalis*, *novem costatum*, *entalis*, *eburneum*, *fissura*, and *strangulatum* as both living and fossil. Mr. Mantell in his tabular arrangement of the organic remains of the county of Sussex (Geol. Trans. vol. iii. second series, 1829), notes a species, which he does not name, in the blue clay of Bracklesham; *Dentalium planum*, in the arenaceous limestone or sandstone of Bognor; *Dentalium cylindricum*, in the sand on Emsworth Common; *Dentalia striatum*, *ellipticum* and *decussatum*, in the Gault or Folkstone marl; and one or more, unnamed, in the Shanklin sand (Lower Green sand). Dr. Fitton figures one species, *Dentalium medium*, from the green sand of Blackdown in his interesting 'Observations on some of the strata between the chalk and Oxford Oolite, in the south-east of England.' (Geol. Trans. vol. iv. second series, 1836.) And he notes *D. ellipticum* in the Gault at Copt Point, on the authority of the Rev. G. E. Smith. In his 'Systematic and Stratigraphical List of Fossils' (Appendix B. to the same memoir) four named species, including *D. ellipticum* and *D. medium*, and an uncertain species, are noted from the Gault of Kent, South Wilts, and Cambridge, and the sands of Blackdown. Mr. Lea in his 'Contributions to Geology,' (1833,) describes two new species, *Dentalium alternatum* and *D. turritum* from the tertiary beds of Claiborne, Alabama, and gives the following summary. 'In Great Britain fourteen species have been obtained from the Lias to the Crag. M. Deshayes's tables give thirty-four, of which thirteen are from the Paris basin, the Eocene period. In this country (America) Dr. Morton has observed casts in the upper green sand of New Jersey and Delaware, and Mr. Say, one species, the *attenuatum*, in the tertiary of Maryland.' Mr. Murchison informs us that he knows of no *Dentalia* in the Silurian or underlying systems of rock.

DENTA'TUS, the surname of the Roman consul Curius, who defeated king Pyrrhus near Tarentum. He is said by Pliny to have been born with teeth, and to have received

the name Dentatus from this circumstance. He gained several victories over the Samnites, Sabines, and others, and was remarkable for his great frugality. When the ambassadors of the Samnites went with a quantity of gold to attempt to bribe him, they found him cooking some vegetables on his fire, and were dismissed with the reply, that he preferred ruling the rich to being rich, and that he who could not be conquered in battle was not to be corrupted by gold. (Horat. Od. i. 12, 41; Florus, i. 15.)

DENTA'TUS, LU'CIUS SICI'NIUS, a Roman tribune, who distinguished himself in battle chiefly against the Æqui and the Sabines. Livy calls him Lucius Siccus (iii. 43). According to Valerius Maximus (iii. 2), he had been in 120 engagements, had forty-five wounds in the breast, and had received an accumulation of honours almost incredible. Through the jealousy and treachery of Appius Claudius he was murdered by the soldiers whom he was appointed to command. He no sooner perceived their design than he stood with his back to a rock, and drawing his sword, killed fifteen of his assailants, and wounded thirty more: at length they ascended the rock, and overwhelmed him with stones from above. On their return to their camp they gave out that they had engaged with the enemy, and that Sicinius had fallen in the battle. (Dionys. Halicarnassensis x.; Livius iii. 43.)

DENTILS. [COLUMN.]

DENTIPORA. [MADREPHYLLÆA.]

DENTIROSTRES. [BIRDS, vol. iv., p. 431; LANIADÆ.]

DENTITION, the formation and evolution of the teeth. The varied processes by which the teeth are formed, developed, and arranged, are among the most curious and complicated operations of the animal economy. The different stages of dentition, in the human being, mark distinct epochs of human life, in which many important changes occur in the physical frame, simultaneously with which new mental powers are developed.

The teeth differ in their organization in several important respects from all other organs of the body. They are of a bony structure, and are placed in the arches of the upper and lower maxillary or jaw-bones. They consist of two sets, of which the one is intended to last only for a short time, while the other is destined to last during the whole term of life. The first are called the temporary and the second the permanent teeth. The temporary teeth, twenty in number, are in general considerably smaller than the permanent, have a less firm and solid texture, and their characteristic forms and prominences are much less strongly marked. The permanent teeth, thirty-two in number, are arranged in perfect uniformity, eight on each side of each jaw, those of the one side exactly corresponding with those of the opposite. They are divided into four distinct classes, which present specific differences in size, form, development, articulation, and use; namely, on each side of each jaw, two incisores, one cuspidatus, two bicuspidates, and three molares. There are no phenomena in the human economy more wonderful than those by which these teeth assume their ultimate form, position, and relations.

Preparation is made for the production of the teeth long before the period of birth. If the jaws be carefully examined about two months after conception, an extremely soft jelly-like substance is found lying along the edge of each maxillary arch. At the third month this has assumed a somewhat firmer consistence, and is contained within a shallow groove of bone, which constitutes the first step towards the formation of the osseous plates between which the teeth are to be ultimately included. The pulpy substance now begins to be partially divided into distinct portions. At the same time filaments of bone shoot across from one side of the groove of bone to the other, and thus define the divisions of the alveoli or sockets, in which the teeth are to be contained. The separate pulps formed by the division of the pulpy substance constitute the rudiments or bases upon which the teeth are formed. As yet they lie upon the vessels and nerves which run along the bottom of the bony groove. They are extremely soft, gelatinous, and semitransparent. Each is partially enclosed in a membrane or sac.

If this sac be opened at the fourth month, a small point of ossification may be distinctly seen deposited upon certain of the pulps. This is the commencement of the formation of the bony substance of the tooth. The ossific matter is formed not by the pulp itself, but is secreted from the blood and deposited upon the pulp by an extremely delicate, thin,

vascular membrane, which covers its surface, and which is closely attached to it by vessels. This membrane, termed the proper membrane of the pulp, is conjectured to be a production of the membrane which covers the bony substance of the jaw, and which is called its periosteum.

The sac which envelopes the whole is thick in its texture, and consists of two layers, which are easily separable after a short maceration, and both of which are vascular. The enveloping sac which loosely surrounds the pulp is attached to the pulp only at its base where the vessels enter, but it is intimately and inseparably connected with the gum, from which it is supplied with its blood-vessels and nerves.

The bony matter is first deposited on the points of the teeth; as the deposition increases, the bone assumes by degrees the appearance of a thin osseous shell spread over the pulp and its proper membrane, which retire as the bone continues to be deposited, so that this bony shell is interposed between the pulp with its membrane and the investing sac.

Almost from its first origin the form of the pulp is nearly the same as that which the crown of the tooth is destined to assume. It is observed that ossification commences on as many points as the future tooth will have eminences on its surface, and that accordingly the incisores and cuspidati commence with one point, and the molares with several.

As the shell of bone increases, the alveoli, or sockets for the reception of the teeth, deepen and separate more completely the one from the other. When the osseous shell has extended so far as nearly to cover the original form of the pulp, the pulp elongates at its base. This elongation of the pulp forms the basis of the root of the tooth. In those teeth which have only one root, a conical shell of bone is formed around the elongated portion of the pulp, which continues to extend in length as the ossification advances. On the other hand, in those teeth which have several roots, the pulp, the point where it begins to elongate, divides into a number of processes, corresponding to the number of roots proper to the tooth; and from the osseous shell a process of bone is sent across from one side of the shell to the other, between the divided processes of pulp, and the ossification is then continued around each respectively.

From the whole then it appears, that an outer lamina of bone is first formed and completed, and that then succeeding laminæ are deposited one within another, the pulp receding as the osseous matter increases, until at length there remains only the permanent cavity of the tooth, lined with its proper membrane, and filled with the remaining portion of the pulp, which now serves as the bed upon which blood-vessels and nerves ramify previously to their entering the substance of the teeth.

Such is the mode in which the osseous matter is formed and deposited; but now a new process takes place. When the bony shell has extended as far as the neck of the tooth, the investing sac attaches itself closely to this point, though it continues to envelop the body of the tooth only loosely. And now a remarkable alteration takes place in the substance of the enveloping membrane, which becomes thickened and much more vascular, particularly the inner layer, over the whole internal surface of which the blood-vessels may be seen obviously enlarged, and capable therefore of receiving a much greater supply of blood. The object of this change in the condition of the membrane is to fit it for a new function which it is destined to perform. From the whole of the internal surface, thus furnished with a greatly-increased supply of blood, a thickish fluid is poured out. This fluid is speedily converted into a dark, solid, chalky substance, which afterwards, by a more perfect crystallization, becomes white and exceedingly hard. This is the enamel, which, first deposited on the points at which ossification had commenced, by degrees covers in one continuous layer the whole crown of the tooth. Thus the office of the investing membrane, which, it has been already stated, is connected with the gum, is the secretion of an inorganic substance, the enamel, and after it has accomplished this office the sac is absorbed; but the tooth itself is the production of a substance independent of the gum, and immediately connected by its vessels, as well as by its secreting membrane, with the bone of the jaw.

Such are the curious phenomena connected with the formation of the teeth. But this account relates only to the formation of the temporary teeth. The rudiments of the permanent teeth are not original and independent, like those of the temporary. The permanent teeth are derived from the temporary, and they remain for a consider-

able time attached to and intimately connected with their parents.

At an early period in the formation of the temporary teeth the investing sac gives off a small process or bud, containing a portion of the essential rudiments; namely, the pulp covered by its proper membrane. This constitutes the rudiment of the permanent tooth. It commences in a small thickening on one side of the parent sac, which gradually becomes more and more circumscribed, and at length assumes a distinct form, though still connected with it by a peduncle. For a time the new rudiment is contained within the same alveolus or socket with its parent, the socket being excavated by the absorbents for its reception by a process unparalleled among the phenomena of physiology. 'It is not,' says Mr. Thomas Bell, whose researches have shed new light on the structure of the teeth, and of whose excellent work we have largely availed ourselves in this account, 'it is not, as has been believed, in consequence of the pressure of the new rudiment upon the bone, that this absorption is produced, but by a true process of anticipation; for I have seen, both in the human subject, and more evidently still in the foal, the commencement of this excavation before the new sac was formed, and consequently before any pressure could have taken place on the parietes of the socket. The absorption does not in fact commence in the smooth surface of the alveolus, but in the cancelli of the bone immediately behind it, where no pressure could operate; and it is only by carefully removing the parietes of the socket, where the excavation is intended to be formed, that the very commencement of the process can be observed. By degrees a small recess is thus formed in the parietes of the alveolus, in which the new rudiment is lodged, and this excavation continues to increase with the increasing size of the rudiment, whilst at the same time the maxillary bone becomes enlarged, and the temporary tooth, advancing in its formation, rises in the socket. The new cell is thus gradually separated from the former one, both by being itself more and more deeply excavated in the substance of the bone, and also by the deposition of a bony partition between them; and the rudiment of the permanent tooth is at length shut up in its proper socket. There is not however, even now, a total disunion between the two teeth, for as the temporary one grows and rises in the jaw, the connecting cord or peduncle elongates; and although the sac from which it is derived by degrees becomes absorbed, it still remains attached to the neck of the temporary tooth, even long after the latter has pierced the gum; and this connexion between the temporary tooth, the permanent rudiment, and the gum, is thus kept up by means of the cord, through a small opening in the top of the new alveolus, which is seen perforating the alveolar process immediately behind each temporary tooth.

'The situation of each permanent rudiment, when its corresponding temporary tooth has made its appearance through the gum, is beneath and a little behind the latter, and rather farther from the centre of the jaw. From the preceding statement then it will be readily understood, that the upper part of the new sac, being by means of the cord connected with the gum, assumes by-and-by the same relation to that substance as that which the temporary rudiment, as before described, had originally sustained; whilst, from its substance being deeply imbedded in the jaw, the vessels and nerves which had entered into the composition of the new process of pulp in its first production, probably become so enlarged and modified in their structure as ultimately to form the true dental branches. This is much more probable than to suppose that a new set of nerves and vessels are given off from the maxillary branches to join the pulps at a distance, through an intervening layer of bone of an indefinite thickness, to supply every new tooth.

'We now therefore find the new rudiment in a state nearly analogous to that in which the parent tooth was originally placed, and with similar relations to the surrounding parts; the sac above attached to the gum, and the pulp beneath covered with its proper membrane, connected by its vessels, &c. with the jaws. The foregoing account will convey an accurate idea, according to my views of this curious subject, of the mode in which the permanent teeth are produced.'

The ossification of the temporary teeth commences, as has been stated, at about the fourth month after conception. At this period the pulps of the whole of the temporary teeth may be observed. There are also distinguishable the pulps

of the first permanent molares; but the latter are not yet very distinct. At the fifth month, or rather earlier, may be distinguished the pulps of the permanent central incisors, though extremely small, and still closely attached to the parent sacs.

At birth the alveoli of the temporary incisors and cuspidati are formed with some distinctness; and partially also the alveoli of the molares. Ossification has advanced on all the temporary pulps, so as to form shells of bone, reaching some way over their crowns. It has also commenced in a minute point on the first permanent molares. The sacs of the permanent incisors and cuspidati may also be distinctly perceived lying in contact with the temporary ones, immediately behind them, and exhibiting in a very beautiful manner the peculiar connexion between them which has been described.

As ossification proceeds, the roots of the teeth continue to elongate, until first those of the incisors, and subsequently the others, can no longer be retained within the alveoli; preparation is now made to facilitate their passage through the gums by absorption of the containing parts.

When the tooth has arrived at this stage it presses upon the gum, a portion of the sac being still interposed. As this membrane has already secreted the enamel, it becomes absorbed at the point where pressure is first made, and the gradual removal of the sac and gum is the consequence. It is not improbable that when the membrane has fulfilled its office, it becomes removed by the spontaneous action of the absorbents, independent of pressure.

The age at which the teeth first make their appearance varies considerably; frequently without any apparent reference to the constitutional powers of the child. Instances are not wanting in which children have been born with two or more teeth. In many other cases the teeth have not come through the gum until fourteen or sixteen months, or even as late as two or three years. In general however dentition may be said to commence at the age of from five to eight months. It usually proceeds in the following order, the teeth of the inferior jaw almost always preceding those of the superior for a longer or shorter time.

From 5 to 8 months,	the four central incisors.
" 7 to 10 "	" " lateral incisors.
" 12 to 16 "	" " anterior molares.
" 14 to 20 "	" " cuspidati.
" 18 to 36 "	" " posterior molares.

These periods are however only given as a general rule, liable to continual exceptions, not only in the time at which the different teeth appear, but also in the relative order of their precedence.

According to Dr. Ashburner, who has paid great attention to this subject, and who has had ample opportunities of observation, the teeth of the first dentition commonly cut in couples; the two anterior incisors of the lower-jaw appear first; then, in perhaps from fifteen to twenty days, the two anterior incisors of the upper-jaw come through; to these succeed the lateral couple of incisors of the lower-jaw; then come those of the upper-jaw. After these the two molar teeth nearest to the lateral incisors of the lower-jaw appear; then the first molars of the upper-jaw; after which come the lower two canine; then the upper canine; then the two second molar of the lower-jaw, and afterwards the corresponding molar of the upper-jaw. The period occupied in the process is about two years from the appearance of the first tooth.

The first formed of the permanent teeth are the anterior molares, on which the first point of ossification may be seen at birth. At about the age of twelve months the ossification on these teeth has proceeded to a considerable extent; also on the permanent incisors, and it has commenced on the lower cuspidati, the upper ones being generally two or three months later. About the time when all the temporary teeth have made their appearance, ossification is found on the points of the bicuspidates, and the bony shells of the teeth before mentioned have acquired considerable size.

Most of the permanent teeth are larger than those which precede them. They are placed during their progress a little behind them; hence they are confined within the segment of a smaller circle; consequently, as they approach more and more nearly to their ultimate size, they must become very much crowded in the jaw. 'The examination of the maxillary bone of a child of about five years old,' observes Mr. Bell, 'will show this fact in a very striking man-

ner. At this period the jaws being considerably deepened by the development of the alveolar processes, the sockets in which the permanent teeth are lodged will be found placed beneath those of the temporary, some higher than others, and the bony shells are closely packed in such a manner as to occupy the least possible space. Thus, in the upper-jaw, the central incisors are situated immediately beneath the nose, the lateral incisors thrown back behind the points of the cuspidati, and the bases of the latter scarcely a quarter of an inch below the orbit: in the lower jaw the cuspidati are placed at the very base of the bone, with only a thin layer beneath them; but the crowding is much less considerable than in the upper jaw, from the smaller comparative size of the incisors.

'At from six to seven years of age the whole of the permanent teeth are more or less ossified, excepting the dentes sapientiae; so that, previously to the shedding of any of the temporary teeth, there are at this time no less than forty-eight teeth in the two jaws; namely, twenty deciduous, the whole of which are perfected, and twenty-eight permanent, in different degrees of development, within the bones.'

At a particular epoch of human life, the temporary teeth are exchanged for a more numerous set, of a stronger and more durable structure, and of increased power of mastication. The original teeth become loose in their sockets; their roots are eaten away; their crown crumbles and recedes from the gums, and at last they fall out. This change takes place in the temporary teeth exactly in the order in which they were originally formed, and in which they cut through the gums. Thus the central incisors of the lower jaw fall away first, then those of the upper jaw, then go the interior lateral incisors, and so on.

The mode in which this change is effected, which constitutes the shedding of the teeth, is by a process of absorption. The anterior parietes of the cavities in which the permanent teeth are contained are removed by the absorbent vessels, in consequence of which the teeth are allowed to advance: next the sockets, then the roots, and lastly the crowns, of the temporary teeth are absorbed. This absorption cannot be solely the effect of pressure produced by the advancing permanent teeth; for the process goes on when such pressure cannot possibly have existed; it is, in part at least, like the preparation of the cell for the reception of the permanent pulp, a true process of anticipation. Neither do the advancing permanent teeth displace the receding deciduous teeth; but the jaw grows and enlarges consentaneously with the increasing bulk and number of the teeth which it is destined to receive.

The change of the temporary for the permanent teeth commences, in the majority of instances, at about seven years of age, 'though,' says Mr. Bell, 'I have occasionally known it to occur as early as five, and as late as eight years and a half. The first permanent molares usually pierce the gum before the loss of the temporary central incisors, and their appearance may be considered as indicative of the approaching change. The following are about the medium periods at which the different permanent teeth are generally cut, but so irregular are they in this respect, that comparatively little dependence can be placed on such a statement. Those of the lower are here indicated, and they most commonly precede the upper by about two or three months.

Anterior molares	.	.	.	6½ years
Central incisors	.	.	.	7 "
Lateral incisors	.	.	.	8 "
Anterior bicuspidates	.	.	.	9 "
Posterior bicuspidates	.	.	.	10 "
Cuspidati	.	.	.	11-12 "
Second molares	.	.	.	12-13 "
Third molares, or dentes sapientiae	.	.	.	17-19 "

Such are the main phenomena which relate to the process of dentition when this operation is performed in a perfectly natural and healthy manner. But this process is exceedingly apt to become deranged, producing evils in the system often most serious, and even fatal, and the preceding account of the natural process will enable us readily to understand the nature, extent, and causes of the diseases which so often result from the morbid progress of the function.

(Bell on the Anatomy, Physiology, and Diseases of the Teeth; Ashburner on Dentition, and some co-incident disorders; Meckel, Man. d'Anat.; Serres, Nouvelle Théorie de la Dentition; De la Barre, Seconde Dentition.)

DENTITION, ANORMAL, DIFFICULT, DISEASES OF. (*Difficult Teething.*) Every infant, at the period of birth, is imperfectly organized. There is no structure and scarcely any tissue of its body which has attained its due consistence and firmness. Several of the most important organs are entirely rudimentary, and there is not one that is perfect either in structure or function. Development is the great process unceasingly carried on at every point of the system. The capillary arteries, the immediate agents by which this process is effected, are the masons and architects by which the various structures are built up; the modellers, by which the due form and the relative bulk of the different organs are communicated and preserved, are the absorbent vessels; and the regulators and controllers of these agents, and of every other power concerned in carrying on the processes of nutrition and growth, are the nerves, and the great central masses in connexion with the nerves, the spinal cord and brain. Hence the sanguiferous system in all the varied states in which it is ministering to the function of secretion is in incessant activity, and the absorbent and nervous systems must necessarily be in a proportionate state of activity. It is indispensable to the due progression of the formative processes that there be maintained a perfect balance between all these varied and complex actions: a failure or a diminution in the action of one system, or a disproportionate energy in the action of either, will at once disturb that balance, and produce the most serious evils in the economy. At the age of infancy such a disturbance the more readily occurs, on account of the imperfect condition of every portion of the organism, no part having yet acquired the firmness of maturity, nor the power of resistance which belongs to mature and perfect structures.

Among the organs the first to be developed after birth are the teeth, and the jaws which are to contain the teeth. These organs are agents indispensably necessary to the performance of a primary and essential function, that of nutrition. Before birth there are no teeth, the nutrition of the fœtus being carried on by nutritive matter derived from the mother. For a considerable period after birth there are no teeth, the nutritive matter by which the infant is to be nourished being still formed for it by the mother. But the infant is ultimately to acquire an existence wholly independent of the mother, and from the moment of its birth, nay, long before the period of birth, processes of preparation are going on in its system which have for their object the formation of an apparatus destined to enable it to prepare and digest food independently of its parent.

This apparatus, from its most rudimentary state, possesses a highly organized and delicate structure; and it is placed in a position in which its progressive development is attended with peculiar difficulties, which at first view would appear insurmountable. A bony structure has to be formed and to make its way through the dense substance of the gums; at the same time the jaws have to attain a bulk fitted to receive these structures when duly prepared and evolved. The too hasty evolution of the teeth, or the too tardy growth of the jaws, produces grievous evils in the system, by the disturbance of that balance which has been already stated to be indispensable to the orderly and safe progress of the developmental actions.

Supposing the formation of the teeth in the jaws to have proceeded quite naturally up to the time proper for their evolution, at that period they are included in a firm membranous envelope, and are covered by the thick and dense gum. When the process of dentition proceeds in a natural manner, the membrane and the gum are absorbed in order to make way for the passage of the teeth. This absorption is accomplished by a stimulus communicated to the absorbent vessels, either by the mere presence of the tooth without direct pressure, or by a moderate and gradual pressure produced by the advancing tooth.

This process, even when accomplished in a perfectly natural manner, is almost always attended with some degree of local inflammation. The gum itself is manifestly red and swollen, and is apparently painful and itching, indicated as well by the obvious occasional uneasiness of the infant, as by the constant desire it evinces to press against the gum everything it can lay hold of. The irritation of the gum extends to the salivary apparatus placed in the mouth and its neighbourhood, as is proved by the increased flow of saliva, which is commonly more or less altered in quality, as well as increased in quantity, being thicker and

more tenacious than the natural secretion. These symptoms of local irritation are usually accompanied by a slight degree of constitutional disturbance, the skin being commonly hotter and dryer, the face occasionally flushed, the bowels more relaxed, and the infant itself more restless and fretful than natural. The irritation of the gum when restricted within a moderate limit seems to be the necessary consequence of the developmental process that is going on. The effect of the local irritation, namely, a determination of blood to the salivary apparatus, occasioning an increased flow of saliva, and that of the constitutional disturbance, namely, a determination of blood to the mucous membrane of the intestines, occasioning diarrhœa, appear to be remedial rather than morbid,—to be evacuations established by nature for the purpose of relieving over-distended vessels and over-excited nerves.

When the infant is in a state of sound health, and when the process of dentition proceeds in a natural manner, the local and constitutional evils attending the evolution of teeth amount to no more than have now been described; but when the infant is in a state either of congenital or acquired disease, or when the natural course of the process of dentition is disturbed, evils result always serious and often fatal.

Suppose that the formative proceeds faster than the absorbing process; that the teeth grow with a rapidity with which the action of the absorbents is not commensurate, the necessary consequences are, that the tooth is forced against the gum, that the investing membrane is compressed between them, and that this pressure is communicated to the delicate and soft pulp on which the organization of the tooth is still proceeding. The effects of the irritation thence induced will vary according to the degree of pressure, the sensibility, and irritability of the individual, and the predisposition of its natural or acquired constitution to disease. In some it may produce only a slight aggravation of the local and constitutional ailments already described; in others it may produce every form of disease to which infancy is subject, attended with every symptom appertaining to such diseases.

In the infant, the mucous membrane which lines the alimentary canal, from its commencement in the mouth to its very termination, is highly sensitive and irritable; the membrane which covers the external surface of the body, the skin, which possesses essentially the same structure as the internal lining membrane, and between which there is the most intimate sympathy, is alike sensitive and irritable; the mucous membrane which lines the air-passages, and which forms the air-vesicles of the lungs, is scarcely less sensitive and irritable. Morbid irritation excited in any of these extended and most important surfaces is readily propagated to the great nervous centres, the spinal cord and brain, in which are induced, often with extreme rapidity, some of the most formidable diseases to which the human body is subject; and from diseases established in the spinal cord and brain disease is reflected back upon the muscles. Thus the most prominent diseases produced by anormal (irregular) dentition have their seat in the stomach, the intestines, and all the organs which form a part of the digestive apparatus; in the external skin, in the air-passages and lungs, in the spinal cord and brain, and in the muscles of voluntary motion.

The irritation attendant on anormal dentition commences in a portion of the mucous surface of the digestive apparatus, and from its source in the mouth it is readily propagated to the stomach, intestines, and liver, producing in the stomach pain, nausea, vomiting, flatulence, acid eructations, &c.; in the intestines, griping pain, flatulence, diarrhœa; in the liver, disordered secretion of bile, in consequence of which the fœcal evacuations are greatly altered in quantity and quality, being at one time too scanty, and at another time too copious, sometimes light or clay-coloured, and at other times dark-green, spinach-like, and preternaturally fœtid, mixed with large quantities of unhealthy viscid mucus. There is also a great proneness to diseased action of the pancreas, owing to its intimate connexion with the salivary apparatus; and there is reason to believe that several states of diarrhœa, so common at the period of dentition, are dependent on a morbid secretion of the pancreatic juice. The urine at the same time is often scanty and turbid, and there is a purulent discharge from the urethra, attended with difficulty and excruciating pain in passing the water.

The external skin sympathizing with the irritation set up in the internal mucous surface, is constantly affected with eruptions of various names and natures, sometimes attacking the scalp, sometimes surrounding the lips and extending over the face, and at other times covering the whole body.

The irritation is propagated from the mucous membrane of the mouth and fauces to that of the air passages and air vesicles, inducing hurried, difficult, and painful respiration, frequent cough, and all the symptoms of inflammation of the lungs, ending frequently in the development of tubercles, and the production of other organic and fatal diseases of the lungs.

There is the closest possible connexion between the skin, the digestive surface, the respiratory surface, and the great nervous centres, the spinal cord and brain. Any irritation excited in the former is readily propagated to the latter. There is a direct route by which the intercourse is established. The nerves proceeding from all these surfaces take a direct course to the spinal cord and brain, where they communicate the irritation which they receive, and excite, among other diseases, more especially that which constitutes hydrocephalus acutus, or water in the head. This disease, among the most formidable to which infancy is subject, and the most common cause of which is anormal dentition, is preceded by the start in sleep, the slight chill, hardly amounting to rigor; the flushed face; the sudden, darting, transient pain in the head; the unusual drowsiness; and then come the sudden start from that deep sleep, with a loud scream; the injected eye, the dilated pupil, followed by the constant rolling of the head upon the pillow, the loss of sight, and the progressively increasing insensibility, and coma. The irritation thus produced in the spinal cord and brain is quickly reflected back upon those muscles the action of which depends upon an influence derived from these great nervous centres—the muscles of volition, which are affected with twitchings, spasms, convulsions, sometimes passing into chorea, epilepsy, catalepsy, and tetanus.

When the acute symptoms induced by inflammation of the brain, followed by effusion, pass away without immediately destroying life, it is often only to leave a state of permanent idiocy far worse than death.

Besides all these evils produced by anormal dentition, there is one specific disease that results from it of a most formidable nature, and often fatal. This affection may be termed the disease of development; it is commonly called infantile remittent fever. The accession of this disease is denoted by languor, lassitude, chilliness, shivering, succeeded by heat of skin, perspiration, and accelerated pulse. The little patient is spiritless, discontented, and fretful. Yawning, sighing, marked increase of irritability, unusual mutability of temper, loss of appetite, perhaps alternating with importunate desire for food, which when given often cannot be eaten, some peculiarity of respiration, and at last impatience of light and sound, accompany or quickly follow a distinct febrile attack. The feverish symptoms disappear or remit soon to recur or exacerbate; and these remissions and exacerbations are characteristic marks of the disease. The colour of health is gone, and the colour often changes. A flush of the countenance, preceding slight rigor and paleness of face, is succeeded by slight headache. There is a remarkable desire to pick, principally the nose, sometimes the lips and fingers, often other objects; frequently the breath is offensive, and cough, headache, and griping pains in the bowels are present, with more or less of sickness, faintness, sighing, starting, more particularly in sleep, moaning in sleep, grating the teeth, sleeping with the eyes half open, and a relaxed or on the contrary an exceedingly constipated state of the bowels. Occasionally the pupils suddenly dilate, perhaps only one pupil, and then as suddenly contract. 'Perspiration is a part of fever, and this is sometimes observed night after night succeeding to no very remarkable heat of skin, but to a great drowsiness, which in itself is a proof of exacerbation, though the accelerated pulse of fever may be wanting. The moaning, picking, or starting, with any of these conditions, constitutes part and parcel of this disorder. Sometimes the ailment is slight in degree, or it may assume an acute form with all the fire and anger of a hot fever. Sometimes it is typhoid in its type. Whatever character may be assumed by this disorder, it is coincident with an irregular course of the development of some organ of the body; and commonly the irregular development is in the nutrient organs, and of these most commonly the teeth and jaws.'

Fatal disease may arise from anormal dentition long before the usual period of cutting the teeth. A turgid condition of the vessels about the soft and delicate pulp, and in the membrane that envelops the whole rudimentary tooth, may compress the dental and even the maxillary nerves; and pressure on these nervous tendrils may, under certain conditions, be tantamount to pressure applied directly to certain parts of the brain; hence irregularity in the course of growth, at the earlier period of teething, may produce a sufficient degree of pressure to excite a high degree of irritation in the brain, producing even fatal convulsions. Many striking cases of this kind are on record, of which the following brief history may serve as an example. A fine healthy-looking child, of a strong healthy mother, died, at thirteen weeks of age, of a convulsive fit. The cause of death was ascertained, at the earnest wish of the mother, by a careful examination of the body after death. The internal organs, for the most part, were healthy; the stomach contained only a little milk; the mucous surfaces of the intestines were free from disease; the contents of the thorax were healthy. In the head the membranes that envelop the brain, and more especially the pia mater, were more tinged with blood than natural, but the brain itself was healthy. The jaws were carefully examined. 'The capsules of the incisor teeth were large and very vascular, much more advanced than usual. With a lancet, the cartilaginous rim of the lower jaw was attempted to be removed, with a view of exposing the capsules of the molar teeth; but these were so unusually distended with fluid, that the instrument cut into them and let it out. This was an example of development proceeding too hastily.'

It is common for the symptoms of irritation which attend on the evolution of the teeth to appear about the third or fourth month; they usually precede the appearance of the teeth by several weeks, and they occasionally subside and then re-appear a short time before the tooth makes its way through the gum.

Disease arising from anormal dentition is not confined to the period of infancy. In children of irritable constitutions in whom the maxillæ are imperfectly developed, the irruption of the second or permanent teeth is sometimes attended with serious and even fatal disorders. Nay, even the period of adolescence is by no means free from severe diseases produced by this same cause: for in consequence of the development of some of the teeth having been preternaturally delayed, or in consequence of an imperfect development of the jaws, at the period when the dentes sapientiæ are about to appear, delicate, nervous, and irritable subjects are not unfrequently affected with swelling of the parotid and submaxillary glands, painful and sometimes periodical affections of the ear and face, slight or recurring ophthalmia, irregular convulsions, epilepsy, and chorea; which affections have disappeared at once upon the irruption of the teeth or the removal of the local irritation.

Animals are not afflicted with these or any analogous evils from the evolution of their teeth, and they are produced in the human species altogether by the unnatural circumstances in which the infant is placed in the present artificial state of society. The chief causes of these grievous evils are—1. Food, unnatural in quality and too great in quantity. It is seldom that an infant lives solely upon its natural food (human milk) during the early months of its existence. If it take other food, that food is either digested or it is not. If it be not digested numerous ailments are produced; if it be digested the system is too highly nourished, and becomes too full of blood, from which it is easy to see that any one or any number of the diseases which have been described may result. 2. The practice too common in this country of keeping the heads of infants and young children very warm by clothing, by their wearing flannel caps, and by having their heads almost constantly wrapped in a warm woollen shawl, from the dread of their catching cold. The naturally great determination of blood to the head is too much favoured by this practice, which co-operates more powerfully than may at first view be apparent with the other circumstances that conspire to produce disordered dentition. 3. The confinement of infants in close and heated apartments, in the impure air of large towns and cities without exercise. Such children in whom all the evils of dentition are most frequently produced in the severest forms, are deprived of the natural stimulus afforded to the varied processes of growth by pure air and active exercise.

The treatment of the various and formidable diseases produced by anormal dentition can never be judiciously conducted without a constant reference to the causes on which they depend. Without a proper regulation of the diet, clothing, air, exercise, and the state of the bowels, nothing can be effectually done to prevent the occurrence of the most formidable of these evils. When they are actually present no remedy can be other than palliative which does not aim at two things; first, the entire correction of every thing ascertained to be faulty in the diet, clothing, &c. &c.; secondly, the removal of pressure upon the nerves, produced by the advancing and unliberated tooth, which occasions all the mischief. 'As soon therefore as any of the affections now described, or any others which can possibly be supposed to arise from this cause, make their appearance, the gums should be carefully examined, and wherever there is any unusual redness or turgescence, and especially if it occur over the part where the next tooth is expected to appear, the including parts should be freely and effectually divided. It is not sufficient that the incision should merely pass through the gum, the lancet must be carried down to the rising tooth itself, and only stopt when the resistance of its point is felt against the edge of the instrument. The form of the gum-lancet should be broad and somewhat rounded, and its edge extremely sharp. The only precaution necessary in its use is so to direct it in making the incision that the cord of connexion between the temporary and permanent tooth shall be carefully avoided, which is readily insured by directing the edge rather towards the outer part of the gum.

'The prejudices of former times against this simple and most efficacious operation are fast yielding to the frequent evidence of its harmlessness and utility. It is impossible for the most prejudiced to witness the effects which continually result from it without becoming a convert to its use. In the midst of the most imminent danger, when death has almost been anticipated as the only relief from severe and hopeless suffering, this simple and trifling operation has, in innumerable instances, restored the little sufferers to their parents in a state of ease and safety, and in so short a space of time as would scarcely have appeared credible.'

There are few cases in the management of disease which require more prompt decision in the application of remedies or more judicious selection of remedial agents than some of the sympathetic affections which have been now adverted to. Life will often depend on the choice of the remedy which is made, and the cautious boldness with which it is administered. It is not possible here to pursue the discussion of this subject further than merely to add that the bowels should be constantly kept in a somewhat loose state; that if a slight degree of diarrhoea be naturally established, nothing whatever should be done to check it; that even when the purging becomes considerable, it should be only moderated, not stopped; and that the most extreme caution should be exercised in meddling with any eruptions upon the skin. (*Bell on the Teeth; Dr. Ashburner on Dentition; Dr. John Clarke's Commentaries on the Diseases of Children; and Copland's Dictionary of Practical Medicine in loc.*)

DEODAND (*Deo dandum*, given to God). By deodand is understood whatever personal chattel occasions the death of a man without the default of another, and also the instrument with which murder is committed. In England deodands are forfeited to the king, to be applied to pious uses and distributed in alms by his high almoner; but the crown most frequently granted the right to deodands, within certain limits, either to individuals for an estate of inheritance or as annexed to lands, in virtue of which grants they are now claimed.

Blackstone supposes 'that the custom was originally designed in the blind days of popery as an expiation for the souls of such as were snatched away by sudden death, and for that purpose ought properly to have been given to holy church, in the same manner as the apparel of a stranger who was found dead was applied to purchase masses for his soul.' But it is perhaps more reasonable to imagine that it was a civil institution intended to produce care and caution on the part of the owners of cattle and goods, and that the subsequent application of the things forfeited has been mistaken for the origin of the law itself. The custom was also a part of the Mosaic Law. (*Exod. xxi. 28.*) In

England it has prevailed from the earliest period, and there is no trace of the deodands having been applied to pious uses. The custom is thus mentioned by Bracton, one of the earliest writers on English law, who lived in the reign of Henry III. 'Omnia quæ movent ad mortem sunt deodanda,' which is Englished in the 'Termes de la Ley.'

What moves to death, or kill'd the dead,
Is deodand, and forfeited.

A different rule prevails when the thing occasioning accidental death is at rest, and is composed of several parts, and when it is in motion. For instance, if a man, in climbing up the wheel of a cart, falls and is killed, the wheel only is forfeited; but if the cart is driven against the man, and the wheel goes over and kills him, not only the wheel but the cart and its loading are forfeited. In cases of homicide, the instrument of death is forfeited, even if it belongs to an innocent party, for which reason, in all indictments for homicide, a value is placed on the weapon used in killing, that the king or his grantee may claim the deodand, for it is no deodand unless it be presented by a jury of twelve men. In modern times juries have taken upon themselves to mitigate these forfeitures, and it is common for the coroner's juries to award a given amount as a deodand, less than the value of the chattel; and though it is said that this finding is hardly warrantable by law, yet the court of King's Bench has usually refused to interfere on behalf of the lord of the franchise to assist so inequitable a claim.

DEOGHUR, a district in the province of Gundwana, forming part of the dominions of the Rajah of Nagpore, and lying principally between 20° and 21° North latitude. It is separated into two divisions, designated Deoghur above the Ghauts and Deoghur below the Ghauts. The division above the Ghauts is an elevated tract of country having the valley of the Nerbudda to the north, and the plains of Nagpore to the south. Its surface is undulating, hills and dales occurring in regular succession; the general direction of the hills is east and west. The division below the Ghauts lies to the south; it is crossed by several ranges of hills branching off from the Vindhyan chain. In other parts, situated between the Wurda and the Wyne Gunga, the country is open and undulating, and watered by numerous streams.

In the time of Aurengzebe, this country was in a very wild and unsettled condition; the Rajah was little more than the nominal head of numerous petty chiefs, and was tributary to the throne of Delhi. Shortly after that time, the Bhoonsla family obtained the chief power in this part of India, and Deoghur became the central part of their dominions. The title of rajah, with a small part of the revenue, was still allowed to the Goond princes, and the show of sovereignty, but without any of its power, is still given to the ancient royal family. The number of towns and villages in the upper division was 1241 in the year 1824, and in the lower division 2075 in 1825; the population of the two divisions was in these years 145,363 and 572,972 respectively, and the revenue amounted to 19,04,828 rupees, or 190,483*l*.

Deoghur, the capital, is in 21° 43' North lat. and 78° 35' East long. It was formerly a place of some consequence, but has long fallen into decay.

DEOGHUR or **BAIDYANATH**, a place of great sanctity in the district of Birbhoom in the north-western extremity of Bengal, in 24° 32' North latitude and 86° 40' East longitude. At a particular season of the year, the roads leading to this place are covered with pilgrims of all ages, both male and female, each bearing a basket, containing the pilgrim's baggage and several small bottles filled with the waters of the Ganges, intended to be poured over the principal idol of the temple which they are about to visit. Some of the pilgrims take with them a larger stock of the sacred water than they require to satisfy their own devotional feelings; this surplus is made a subject of traffic with those who, coming from other parts of the country, have not been able to provide themselves with water from either of the Prayagas. The government imposes a small tax on each pilgrim, the exacting of which is justified, on the ground of its gratifying the natives, as an evidence of toleration on the part of their foreign rulers.

(*Report of Committee of Commons on Affairs of India, 1832.*)

DEOGHUR. [DOWLETABAD.]

DEPARCIEUX, ANTOINE (often written, but erroneously, *De Parcieux*), an able mathematician, was born in 1703 at the village of Cessoux near Nismes. His father was an humble peasant, and unable to afford him the least education; but the display of his precocious talents induced an opulent gentleman in his neighbourhood to place him in the College of Lyons, where his progress in his studies was rapid and striking, especially in the mathematical branches of science. After finishing his course in this institution, he repaired to Paris, without money and without friends; but he turned his talents to account by drawing sun-dials, and engaging in other employment of this kind, by which he was able to obtain a subsistence. His accuracy in these drawings being remarkable, he at length acquired an attachment to the pursuit, and obtained ample employment to secure him a comfortable livelihood. He afterwards appears to have turned his attention to machinery; and probably his talents were extensively employed in civil engineering and other collateral subjects. He died September 2nd, 1768, aged 65.

His publications were as follows:—

1. *Tables Astronomiques*, 4to. 1740.
2. *Traité de Trigonometries Rectiligne et Sphérique*, avec *Traité de Gnomonique et des Tables de Logarithmes*, 4to. 1741.
3. *Essai sur les Probabilités de la Durée de la Vie Humaine*, 4to. 1746.
4. *Réponse aux Objections contre l'Essai* (the last work), 4to. 1746.
5. *Additions à l'Essai*, &c. 4to. 1760.
6. *Mémoires sur la Possibilité et la Facilité d'amener auprès d'Estrapade à Paris les eaux de la rivière d'Ivette*, 4to. 1765.

Besides these separate works, he published sixteen memoirs amongst those of the Paris Academy, between the years 1735 and 1768.

Déparcieux was created Royal censor and member of the Academy of Sciences in Paris. He was also a member of the Academies of Berlin, Stockholm, Metz, Lyons, and Montpellier.

DEPARTMENT (or in French **DÉPARTEMENT**), a territorial division of France, introduced by the States General in the latter part of the reign of Louis XVI. We shall take this opportunity to give some account of the territorial divisions of France as they exist at present.

A commune is the smallest territorial division in the present system of France. In the rural districts and in the smaller towns a commune may be considered as equivalent in area and population to our ordinary parishes, or to the townships into which our more extensive parishes are divided. It is only in respect of area and population that we compare the communes of France with our own parishes: the two divisions were made for different purposes, the parish being an ecclesiastical division, which existed in France as well as in England, while the commune was for civil or military purposes. There is moreover this difference, that while our larger towns and cities (especially those whose extent and importance are of an antient date, such as Norwich, Exeter, Bristol, or York) consist of several parishes, the larger towns of France, with the exception of Paris, form but one commune. The term commune, which is nearly equivalent to corporation, is of antient date. When Louis VI. (le Gros) sought to raise from the towns of the royal domain a burgher militia as a substitute for the troops of his rebellious and disorderly vassals, and in order to form an alliance between the crown and the commons by sheltering the latter against feudal oppression, he formed the freemen inhabiting the towns into *communautés* (in the Latin of the middle ages *communitates*) or corporations, gave them power to raise troops from among themselves, and conferred upon a municipal body, constituted for the purpose, an authority over these troops similar to that which had been exercised over the baronial levies by the great lords themselves, and by their subordinates, the counts, or governors of towns, the viscounts, castellans, &c. These are not to be regarded as the first municipal corporations which had existed in France. Under the Roman dominion there were many; but during the distracted reigns of the later Carlovingian princes, these corporations had mostly, if not entirely, become extinct. The militia of the towns was designated in the Latin of the middle ages *communiæ* (*communes*), *communitates parochiarum* (the commonalties of the parishes), or *burgenses* (the burghers or

burghesses). Where the town consisted of several parishes the troops were formed into smaller bodies according to their parishes, and marched into the field in those divisions, the parochial clergy accompanying their respective parishioners, not to join in the conflict, but to discharge their spiritual duties of preaching to them, confessing them, and administering religious rites to the dying. Some communes consisted of a number of small towns united under one corporation charter. In process of time the greater barons followed the example of the king, in order to become independent of their vassals, among whom the like insubordination existed as among the vassals of the king.

The municipal officers were generally designated *Scabini* or *Echevins*, and the principal of them had the title of *Major* or *Maire* (Mayor). The communes enjoyed many rights and exemptions; they fortified their respective towns, and were, in fact, so many municipal republics scattered over the kingdom, constituting the most substantial bulwark both of the public liberty and the rights of the crown against the encroachments of the nobility. As however the regal power gained strength, the influence and importance of the communes declined. Their militia came into disuse when the kings of the race of Valois began to form a standing army; and upon various causes or pretexts many of the incorporated towns lost their charters, and returned under the jurisdiction of their feudal lords. Under the present system, the whole of France, the country as well as the towns, is divided into communes, and the local administration and the management of the revenues of each are placed under a municipal officer, who may be compared perhaps with our constable or headborough, but who bears the same title, that of *Maire*, which was borne by the head of the antient communes. He is appointed by the king, or the prefect of the department, and is assisted by a communal council, the members of which are chosen by the communal electors, who are those inhabitants who pay most direct taxes, in the proportion of one-tenth to the whole population. (*Loi sur l'Organisation Municipale*, 21 Mars, 1831.) As the plan in France has been to assimilate the divisions for civil and ecclesiastical purposes, we believe that the communes may in the rural districts and the smaller towns be regarded as ecclesiastically equivalent to our parishes. Each has its church and its curé or clergyman. Some have also succursales or chapels of ease. The larger towns have several churches.

A canton is a division consisting of several communes, over which a judicial officer entitled *justice de paix* (justice of the peace) is appointed. These functionaries receive a small salary; they decide civil suits if the amount in question is small: and all suits whatever must be heard by one of them (in order that he may if possible bring the parties to an agreement) before the cause is carried into a higher court. The cantons into which the arrondissements of St. Denis and Sceaux (comprehending the metropolitan department of the Seine, beyond the limits of Paris) are divided, contain from six to thirteen communes each, or upon the average nearly ten each; but the cantons which are farther from the capital contain a greater number: the average of France is nearly fifteen communes to a canton.

An arrondissement (circle) comprehends several cantons, seven on the average of France: the two arrondissements of the department of the Seine above-mentioned have each four cantons. The municipal officers of the arrondissements will be noticed presently.

A department consists of several arrondissements, usually four or five: some departments have only three arrondissements; others have as many as six. The substance of the following account of the departmental administration we take from the *Dictionnaire Universel de la France*. Although it immediately applies to the early part of the reign of Bonaparte, it is (in the leading points at least), we believe, applicable to the present state of France. There are at present in France eighty-six departments.

At the head of each department is an officer entitled *préfet* (prefect), who has alone the administration of the local government. His usual residence is at the departmental capital; but he makes every year a circuit of inspection through his department, and gives an account of the result of his circuit to the proper officer of the central government at Paris. He is not allowed to be absent from his department without the permission of the government, which he obtains through the *ministre de l'intérieur* (mi-

nister of the interior or home secretary). He is assisted in some of his duties by a conseil général de département (general departmental council), composed of sixteen, twenty, or twenty-four members, from different parts of the department, elected by the assemblies of arrondissements, which consist of the highest taxed inhabitants, in the proportion of 1 to 1000. This council assembles annually at a time fixed by the government, nominates one of its members president, and another secretary, and proceeds to its business, which must not occupy a session of more than fifteen days. The business of the council is to apportion between the arrondissements the direct taxes which are required by the general government; to hear and determine upon appeals made by the councils of arrondissements against this assessment; to levy, within certain limits fixed by law, an additional tax, destined, like our county rates, to meet the expenses of the local administration; to audit the account yearly rendered by the prefect of the expenditure of this local revenue; and to express, in a report addressed to the minister of the interior, an opinion upon the condition and wants of the department. The prefect is further assisted by a conseil de préfecture (prefectorial council), consisting of three, four, or five members, which decides upon individual appeals for an entire exemption or a reduction of the direct taxes; and upon questions arising from the execution of public works, whether arising between the government and the contractors as to the particulars of the contract, or between the contractors and parties who complain of injuries sustained at their hands, and upon the indemnity due to individuals whose possessions have been required for carrying on public works. The prefect when present at the sittings of this council acts as chairman, and in case of an equal division has a casting vote.

The arrondissements are under the administration of a sous-préfet (sub-prefect), subordinate to the prefect of the department, to whom he addresses a memorial on anything of importance to the arrondissement, assigning the reasons on which his opinions are founded. He receives and settles the accounts of the maires of the several communes. He is assisted by a conseil d'arrondissement (council of the arrondissement), consisting of eleven members, elected by the cantonal assemblies, consisting of the highest taxed inhabitants, in the proportion of 1 to 100. This council, like that of the department, meets at a time fixed by the government, and has a session limited to fifteen days: it has a president and secretary appointed by and from itself: its duties are—to apportion between the several towns and villages the direct taxes to which the arrondissement has been assessed by the departmental council; to give an opinion, with the reasons subjoined, upon appeals of towns and villages against the proportions levied upon them; and to audit the sub-prefect's account of the expenditure of that part of the departmental revenue assigned to meet the expenses of his administration; and to make a report to the prefect of the wants and condition of the arrondissement similar to that which the departmental council addresses to the minister of the interior.

As the capital of the department is also the chief place of an arrondissement, the prefect, and the prefectorial (not the departmental) council discharge in that arrondissement the duties which in the other arrondissements are assigned to their respective sub-prefects and councils.

The departments and arrondissements are electoral divisions. The members of the Chamber of Deputies are chosen for the departments, not for single towns, however important or populous; so that the deputies are all, according to our phrase, county members. The electors of each department are divided into collèges électoraux: each arrondissement has one of these, and each electoral college elects one deputy. There are 459 deputies for all France, and the number of electors is about 200,000 in all. Some departments have only between 300 and 400 electors, and return two deputies; that of the Seine reckons above 15,000, and returns 14 deputies. Most of the others have between one and two thousand, and return from four to six deputies each. The property qualification for an elector is the annual payment of 200 francs of direct taxes, and that for a deputy 500 francs. An elector must be above 25 years of age, and a deputy above 30. (*Loi relative aux Elections*, 19 Avril, 1831.) The elections are direct, and not graduated, as those under the constitution of the year VIII., or of the present Spanish Cortes.

Each arrondissement has a court of justice, entitled tri-

bunal de première instance, which, except in a very few cases, has its sittings at the capital of the arrondissement. These courts commonly consist of three or four ordinary and two or three supplementary judges: a few arrondissements which include large towns, such as Marseille or Bordeaux, have a considerably greater number of judges, who are divided into two or more sections. To each court there is a procureur du roi, or attorney general; and where the court consists of two or more sections, there are deputy attorneys. Each department has a tribunal criminel (criminal court), or cour d'assise (assize court), consisting of a president, who is a counsellor of the cour royale, to the jurisdiction of which the department is subject, two ordinary and two supplementary judges: to each court is attached a procureur du roi, or attorney general, and a greffier, or registrar. These courts, except in a few instances, have their seat at the capital of the department. Besides these courts, there are in different parts of France twenty-seven higher tribunals, called cours royales, consisting of from twelve to thirty-three salaried judges. Each of these courts has under its jurisdiction several departments. There is an appeal from these courts on questions of law, not of fact, to the supreme court, cour de cassation, at Paris. The departments are also formed into nineteen divisions militaires, or military districts: the head-quarters of these districts are fixed at some important town, usually at the capital of one of the included departments.

A department usually constitutes an ecclesiastical diocese. In a few instances two departments are comprehended in one diocese; and in one or two cases, a department is divided between two dioceses. The dioceses of France amount to eighty, of which fourteen are archbishoprics, and sixty-six bishoprics.

The instruction of youth in France being under the surveillance of government, has occasioned an arrangement of territory with a view to this object. Twenty-six districts, coincident with those respectively subject to the cours royales (except that the Island of Corsica is united to the departments subject to the cour royale of Aix), are under the direction, in matters relative to education, of as many local administrations or academies, which administrations are subject to the control of the great central body, the University of France, which has its seat in Paris. Each academical district is under the superintendence of a rector and an academical counsel, who inspects the schools of the district, and report thereon to the central administrative body. This body consists of a grand-master, who bears the title of minister of public instruction, and has a seat in the cabinet, and of a council composed of ten members. The province of the council is to superintend the business of instruction through the country generally, to judge and remove incompetent teachers, &c. The rector has the appointment of the teachers in the public collèges, or high schools, throughout France, upon the recommendation of the local authorities, and after strict examinations instituted by them.

In extent, the departments of France, with the exception of the metropolitan department of Seine, are more uniform than the counties of England. The department of Gironde, which is the largest, comprehends an area of 3954 square miles, about equal to the English counties of Devon and Cornwall. The department of the Seine comprehends an area of 183 square miles, not much greater than the area of Rutlandshire, and not much above two-thirds of that of Middlesex. The department of Tarn and Garonne, the smallest except that of Seine, comprehends an area of 871 square miles, and is rather larger than the counties of Cambridge, Hereford, Nottingham, or Leicester. The average extent of a department is 2380 square miles, rather greater than the area of Devonshire, but rather less than that of Lincolnshire. A great part of the French departments take their names from the mountains or rivers or parts of rivers which are within their limits.

The subdivisions of a department may, for their relative size, be compared with those of the county of Kent, the French arrondissements corresponding to the Kentish lathes, the cantons to the hundreds and liberties, and the communes to the parishes. The hundreds are however smaller in proportion and more numerous than the cantons. For the origin of the communes, see Raynouard, *Histoire du Droit Municipal en France*, 1829.

DEPARTURE, a nautical term for the number of miles which a ship has sailed east or west. Thus, supposing a

ship's course to be oblique to the meridian, there is a right-angled triangle, of which the hypotenuse is the course sailed over; one side on the meridian is the difference of latitudes of the beginning and end of the course (reduced to miles), and the other side, perpendicular to the meridian, is the *departure* (so called). Its use is to get a rough notion of the quantity by which the ship's longitude has changed, supposing the whole course so small that the portion of the sphere which contains the triangle may be considered as a plane. For the number of miles in the course multiplied by the sine of the angle which it makes with the meridian gives the departure in miles, which can be turned into minutes and seconds of longitude by dividing by the cosine of the latitude, and counting $69\frac{1}{2}$ miles to a degree in the result. But the rough purposes which this process answers are sufficiently well consulted by the tables which are to be found in all works of navigation.

DEPLOY, to extend in a line of small depth, an army, a division, or a battalion which has been previously formed in one or more columns: this may be done either for a review or preparatory to making a charge upon the enemy.

DEPORTATION. (Civil Law.) [BANISHMENT.]

DEPOSITION in its extended sense means the act of giving public testimony, but as applicable to English law the word is used to signify the testimony of a witness in a judicial proceeding reduced to writing. Informations upon oath and the evidence of witnesses before magistrates and coroners are reduced into writing in the very words used by the witnesses, or as near as possible thereto. Evidence in the Court of Chancery is taken in written answers to interrogatories, which are also in writing, either by commissioners appointed by the court for that purpose in the particular cause, if the witness resides at a greater distance from London than 20 miles, or if he resides nearer or is otherwise willing to appear, before the examiners of the Court of Chancery. The course of the Ecclesiastical Court following the practice under the civil law, is also by written interrogatory and answer. The Court of Chancery has power to grant a commission for the examination of witnesses residing abroad; and by the 1 Wm. IV., c. 22, extending the provisions of the 13 Geo. III., c. 63, the courts of law at Westminster, in actions pending before them, have power to order the examination of witnesses residing in any of his majesty's foreign dominions. When a witness is above the age of 70, or very infirm, or about to go abroad, so that his testimony may be lost before the regular period for his examination arrives, the Court of Chancery will order him to be examined *de bene esse*, as it is termed; that is, his examination is received for the present, and will be accepted as evidence when the proper time for taking the other evidence in the cause arrives, if the witness cannot be then produced. Courts of law do not possess similar power without the consent of both parties, but in order to enforce consent they will put off the trial at the instance of a defendant, if the plaintiff will not consent; and if the defendant refuse, will not give him judgment in case of nonsuit.

The Court of Chancery will also, upon bill filed by a person in the actual and undisturbed possession of property, and who has therefore no means of making his title the subject of judicial investigation, but which nevertheless may be materially affected by the evidence of living witnesses, allow the witnesses to be examined in *perpetuam rei memoriam*, that is, to perpetuate testimony. This is done in order that if any of the witnesses should die before the title to the property is disputed, their evidence may be preserved, otherwise a claimant might lie by until all the evidence against him was lost.

Depositions are not admitted as evidence in courts of law, unless the witness is either dead, or from some cause beyond the control of the party seeking to read the deposition, cannot be produced, or against any other persons than the parties to the proceeding in which they were taken, or claimants under them, and who had the opportunity of cross-examining the witness. In cases however relating to a custom, prescription, or pedigree, where mere reputation would be good evidence, a deposition may be received as against a stranger.

Depositions taken in Chancery *de bene esse* before answer put in, unless the defendant is in contempt for refusing to answer, are not admissible as evidence in a court of law, because until the defendant has answered he could not have an opportunity of cross-examining the witness; but the Court of Chancery will sometimes direct such depositions to be

read. Such order however, while it concludes the parties, is not binding upon the court of law; of course, however, if the depositions be not read and the decision should be contrary to justice, the Court of Chancery would interfere as between the parties. [EQUITY, EVIDENCE.]

DEPRESSION (Algebra), the reduction of an equation to a lower degree, by dividing both sides of it by a common factor. Thus $x^3 - x - 6 = 0$ having been found to have 2 as one of its roots, is *depressed* to an equation of the second degree by dividing by $x - 2$, which gives $x^2 + 2x + 3 = 0$; that is, the two roots of the latter equation are the two remaining roots of the former.

DEPRESSION, ANGLE OF, is the angle by which a line drawn from the eye to any object dips below the horizon. [ELEVATION, ANGLE OF.]

DEPTFORD. [GREENWICH.]

DE'RBEND, a town in the Russian government of Georgia, on the Caspian Sea, about $42^\circ 12'$ N. lat. and $43^\circ 20'$ E. long. A branch of Mount Caucasus, which runs eastward to the Caspian Sea, terminates about a mile from its shores. As the mountain ridges in no other place come so close to the sea, the extremity of this steep and nearly inaccessible ridge offered a very advantageous point for erecting fortifications to command the road along the coast. The town is built on the declivity with which the range terminates, and forms a parallelogram about fifteen miles in length, but only 400 yards across. The walls which include it on the north and south are continuous to the sea. There are two large gates in these walls, through which the road passes, and which may be shut at pleasure. Hence the town derives its name, which signifies *the shut-up gates*. The walls, which are of great antiquity and very strong, are built of hewn stones, and not less than ten yards high, and in many places ten feet thick. They are fortified with round and square towers. To the west of the town is the citadel, on a more elevated eminence, which is also well fortified. Derbend contains about 4000 inhabitants, but some travellers make its population 12,000. Many coarse stuffs of silk and wool are made here. Its commerce by the Caspian Sea is not considerable, the harbour being so shallow that only boats can land, and vessels remain at a distance of nearly a mile from the shore. (Bieberstein and Reineggs.)

DERBY, the capital of the county to which it gives name, is in the hundred of Morleston and Litchurch, on the right or west bank of the Derwent, a feeder of the Trent, 114 or 115 miles NNW. of London, in a straight line, or 126 miles by the road through St. Albans, Dunstable, Stoney Stratford, Northampton, Market Harborough, Leicester, Mount Sorrel, and Loughborough: in $52^\circ 55'$ N. lat., and $1^\circ 29'$ W. long.

The municipal and parliamentary limits of the borough of Derby coincide, and comprehend the whole of the two parishes of All Saints and St. Werburgh, and portions of the parishes of St. Michael, St. Alkmund, and St. Peter. All that can properly be considered as the town of Derby is within the borough limits, which enclose an area of 1660 statute acres. (*Boundary Reports and Municipal Corporation Reports*.)

We may consider Derby as having risen from the ruins of the Roman station, Derventio, which was on the site of Little Chester, a hamlet just out of the boundary of the borough and on the opposite side of the river; or as having been a British town upon the British road, the Rykneld, or Icknield-street. Of this Roman station, Dr. Stukely was able to trace the wall quite round: the inclosure was oblong, and contained five or six acres; streets or roads were visible in the fields near it, which he supposed to be the suburbs. Coins of brass, silver, and gold, with antiquities of every kind, have been found, and the foundations of buildings are still sometimes discovered. There are the foundations of a Roman bridge over the Derwent at Little Chester, which may be seen when the water is clear, or felt with an oar. (Hutton, *Hist. of Derby*.)

In the time of the Saxons Derby was called Northwor-thige; the name of Deoraby (Derby) is said to have been given it by the Danes, by whom it had been captured. The etymology of this name has been much disputed: we think that the names of the town, of the neighbouring village of Darley, of the Roman station, Derventio, and of the river (the Derwent) all contain the same British or Celtic root, 'dwr,' water. Skinner (*Etymologicon Linguae Anglicanae*) derives Derwent from the above root, and

'gwen' or gwin, clear or bright; and the name of the town from that of the river, with the addition of the Anglo-Saxon termination 'bye,' a habitation. Derby was recovered from the Danes by Ethelfleda, countess of Mercia, and daughter of king Alfred, who took the castle by storm, A.D. 917 or 918. It was again taken by the Danes, and recovered from them by king Edmund I. A.D. 942.

In the time of Edward the Confessor, Derby was a royal burgh, with 243 burgesses, besides 41 who occupied land adjoining to the town; but at the time of the Norman survey the town was greatly reduced, having only 140 burgesses, 40 of whom were of inferior degree: 103 dwellings were waste and empty which had formerly paid taxes. The castle probably went to ruin about the same time: its site is still called the castle-hill and the castle-field. The last remains of the building are said to have disappeared about 250 years since. Hutton traced one of the mounds of it 80 yards long. From the time of the Conquest no historical event of interest is connected with Derby for several centuries. King Charles I. marched through Derby soon after he set up his standard at Nottingham; but in the same year the town was garrisoned by the parliamentarians under Sir John Gell, and appears to have remained in the hands of that party through the war; the garrison however was removed in 1645. In December, 1745, the young Pretender, with his army, entered the town, but staid only two days, retreating into Scotland on the approach of the duke of Cumberland. (Pilkington, *Present State of Derbyshire*; Lysons' *Magna Britannia*.)

The town of Derby has received many charters; one each from John, Henry VI., Edward VI., James I., and Charles I., and two from Charles II. The last charter of Charles II. was, up to the passing of the late Municipal Reform Act, the governing charter; but Derby claimed to be a borough by prescription. Under the new Act, Derby is divided into six wards, and has twelve aldermen and thirty-six councillors.

Derby is situated in a luxuriant and well cultivated vale, surrounded with beautiful scenery. The streets in the older parts of the town are narrow and winding. The houses are mostly of red brick, the public buildings of stone. The market-place is not large, but commodious; a new market, adjacent to the old one, and communicating with it by a passage under the new town-hall, was several years since built by the corporation. The churches of Derby are six, one for each of the parishes mentioned above, and another erected within the last few years. All Saints (antiently and still popularly Allhallows church) is on the east side of the town not far from the river: the body of the church is a Roman Doric edifice by Gibbs, opened for divine service in 1725; the tower, erected about the time of Henry VIII., is in the perpendicular English style and of peculiar beauty; its general arrangement and details are very fine. It is 178 feet high (Hutton), and its situation adds to the effect of its elevation and its fine architecture. This church was formerly collegiate. The new church, St. John's, is a handsome Gothic building, but in a bad situation. Another handsome new church (that of Trinity), on the London road, has been paid for by public subscription. The new town-hall, between the old and new markets, is a handsome building with an Ionic portico on an elevated basement through which is the communication between the old and new markets. The county-hall is a large but heavy building of freestone, erected in 1660; new buildings have been erected behind the county-hall for holding the assizes and quarter-sessions. The borough jail is a plain, substantial, and convenient building; it was formerly the county prison, but not admitting the classification of prisoners required by the recent act, it was sold by the county to the corporation, and a new county prison, with every convenience for classing the prisoners, has been erected.

Derby has a theatre and an assembly-room. There are places of worship for different classes of dissenters, one each for Presbyterians, Independents, Particular Baptists, Quakers, Roman Catholics, and Swedenborgians; two for the General Baptists and five for different classes of Methodists. There is a stone bridge of three arches, a wooden bridge and a towing bridge over the Derwent, and three stone bridges across the Markeaton brook, which flows through the town into the Derwent. Derby is lighted with gas, and supplied with water from the Derwent.

The principal manufactures are of silk and cotton goods,

porcelain, jewellery, and ornamental articles made of the various kinds of spar found in the county, red and white lead, lead-pipe, sheet-lead, cast-iron, ribbed stockings, bobbin-net, and other lace. There is a considerable printing and publishing establishment and several printing offices.

In the early part of the eighteenth century the Italians exclusively possessed the art of spinning, or, as it is technically called, 'throwing' silk, and the British weaver had to import thrown silk at an exorbitant price. In 1702 a Mr. Crotchet erected a small silk-mill; but his capital and machinery were insufficient, and he failed. In 1717 Mr. John Lombe, who had in disguise and by bribing the workmen, obtained access to the machinery of the silk-throwsters of Piedmont in Italy, agreed with the corporation of Derby to rent, on a long lease, for 8*l.* a year, an island or swamp in the river Derwent, 500 feet long and 52 wide. Here he erected, at a cost of 30,000*l.*, an immense silk-mill, now the property of the corporation, the lease having expired. The foundation was formed with oaken piles 16 to 20 feet long, and over this mass of timber was laid a foundation of stone on which were turned stone arches that support the walls. In 1718 Lombe took out a patent, and was proceeding successfully in his business when he died, cut off, as it was thought, by poison, through the agency of an Italian woman, employed by the Italian manufacturers whose business he had drawn away to himself. He was succeeded in his mill by his brother William, and afterwards by his cousin Sir Thomas Lombe. The accounts of the machinery of this immense mill have been much exaggerated: the wheels have been said to amount to 26,000; Hutton's authority is the best, for he served an apprenticeship of seven years in the mill, and he reduces these wheels to 13,384. The whole was moved by one water-wheel. Many throwing-mills have since been erected at Derby, and this branch of industry may be regarded as the staple of the town. The cotton manufacture is of later introduction and of smaller extent. The manufacture of porcelain was introduced nearly a century ago; and the articles, both in design and execution, have been carried to a high pitch of excellence: the making of figures and ornaments in what is termed 'biscuit ware,' was for some time peculiar to this town, and we believe is so still. The spars of the county, especially the fluor spar or 'blue John,' are wrought into vases and other ornaments, and the black marble of Ashford into vases, columns, chimney-pieces, &c. These spar and marble-works were for some time carried on in the building erected by Crotchet in the year 1702 for a silk throwing-mill; the turning-lathes were set in motion by a water-wheel.

The population of Derby amounted in 1831 to 23,627, of whom 11,269 were males and 12,358 females. Of 5780 males upwards of 20 years of age, 140 were engaged in agricultural pursuits, 953 in manufactures or making machinery, 2714 in retail trade or handicrafts, 1172 in miscellaneous labour, and 85 were servants. The number of capitalists, bankers, and professional or other educated men was 427, and the occupation of 289 was not stated. The population had increased very much in forty years—in 1792 it was 8563; in 1801, 10,832; in 1811, 13,043, and in 1821, 17,423. As, since 1831 many new buildings have been erected, and the place is said (*Report of Commiss. on Munic. Corporations*) to be flourishing, we shall not be far wrong in estimating the present population at 28,000.

Derby returns two members to parliament. It returned burgesses to parliament, 26 Edward I., and has continued to do so ever since. The number of parliamentary electors registered in 1832 was 1384, viz.: 372 freemen and 1012 ten-pound occupiers. Derby is also the chief place of election, and one of the polling stations for the southern division of Derbyshire. The assizes for the county are held here, also the Epiphany, Easter, and Michaelmas sessions; the Midsummer sessions are held at Chesterfield. The borough sessions of the peace are held quarterly before the Recorder; a petty sessions is held daily. There are Courts of Record and of Requests for the borough. The principal market is on Friday. A cattle-market is held once a fortnight on Tuesday. There are nine fairs in the year for cattle, cheese, pedlery, &c., which are, for the most part, well attended. The river Derwent was, several years since, made navigable from the town of Derby to its junction with the Trent, but, since the opening of the Derby canal, the navigation has been disused. This canal branches from the Trent and Mersey (or Grand Trunk) canal at Swarkestone, a few miles south of Derby, runs northward, and intersects the

Derwent at Derby, a towing-bridge being thrown across that river. From Derby the course of the canal is eastward until it joins the Erewash canal at Sandiacre. Over the Markeaton brook, which runs through Derby, the canal is carried in a cast-iron trough or aqueduct. From Derby a short branch of this canal extends to Little Eaton, three or four miles north of Derby, with two arms to the quarries on Little Eaton common. The Derby canal is 44 feet wide at top and 24 feet wide at bottom, and 5 feet deep. Derby is supplied by this canal with coals, building-stone, gypsum, and other things.

There were formerly four religious houses at or close to Derby; an abbey (St. Helen's) of Augustin canons, a nunnery of Benedictines, and houses of Dominicans and Cluniacs. St. Helen's Abbey was founded by Robert de Ferraris, or de Ferrers, second Earl Ferrers. This abbey appears to have been first established in Derby town, and afterwards removed to a site about a mile north of Derby, where has subsequently risen the village of Darley or Darley Abbey. Its yearly revenue at the suppression was 285*l.* 9*s.* 6*d.* gross, or 258*l.* 13*s.* 5*d.* clear. The Benedictine nunnery, founded by one of the abbots of St. Helen's, had, at the dissolution, a yearly revenue of 21*l.* 18*s.* 8*d.* gross, or 18*l.* 6*s.* 2*d.* clear. There was one hospital, or perhaps two, for leprous persons.

There are several alms-houses at Derby: those founded by the countess of Shrewsbury, in 1599, for eight men and four women; those founded by Robert Wilmot, in 1638, for six poor men and four women, now for four poor men and four women; Large's Hospital, founded by Edward Large, in 1709, for five clergymen's widows, and enriched by subsequent donations. The countess of Shrewsbury's almshouses were rebuilt by the late duke of Devonshire, about 1777, in a style of architecture which has been considered too ornate for a charitable foundation of so humble a character. Thirteen neat and substantial almshouses have been lately erected from the funds of a charity bequeathed 300 years ago by Mr. Robert Liversage to the parish of St. Peter. There is a county infirmary equal to the accommodation of eighty patients besides those who have infectious disorders. The building is plain and neat in its architectural character, built of hard whitish stone. The internal arrangements, which are exceedingly convenient, were chiefly planned by the late William Strutt, Esq. There are also in the town 'a self-supporting charitable and parochial dispensary,' a ladies' charity for the assistance of poor women during their confinement, and many friendly societies, or benefit clubs.

There were in Derby, in 1833, one boarding-school containing 20 girls, and twenty-five day-schools, of all kinds, in which instruction was given to nearly 800 boys, 300 girls, and between 200 and 300 children whose sex is not discriminated in the returns. The grammar-school, one of the twenty-five mentioned above, is supposed to be one of the most antient endowments of the kind in England. It was formerly very flourishing, and enjoyed a high reputation, but at the time of the return had only one or two scholars. At present (1837) we are informed that it is again getting into repute. Two of the day-schools are on the 'national' system, and one on the Lancasterian system, and three are infant-schools. The number of Sunday-schools was twenty-four, and in these were instructed 3198 children, viz.: 1152 boys, 1326 girls, and 720 whose sex is not mentioned. In some of the Sunday-schools the children are taught writing and arithmetic on an evening in the week; to some schools lending-libraries are attached.

Of institutions for literary and scientific purposes there are—The Philosophical Society (originally held at the house of Dr. Darwin), with a good library, a collection of fossils, and mathematical and philosophical apparatus; the Permanent Library, which has lately been much enlarged, and has a public news-room and museum attached to it; and the Mechanics' Institution, the members of which have lately erected a handsome and spacious room for their meetings. Two weekly newspapers are published at Derby.

(Hutton's *History of Derby*; Glover's *History of Derbyshire*; *Report of Commissioners of Municipal Corporations and other Parliamentary Papers*; *Communication from Derby*.)

DERBYSHIRE, a midland county of England, bounded on the north-east by Yorkshire, from which it is partly separated by the rivers Derwent, Rother, and Sheaf; on the north-west by Cheshire, from which it is in this quarter se-

parated by the river Etherow; on the west by Cheshire, from which it is here separated by the river Goyt, and Staffordshire, which latter county bounds it also on the south-west (the Dove separates Staffordshire from Derbyshire on the west, and the Dove and the Trent on the south-west); on the south-east by Leicestershire, from which it is partly separated by the Trent; and on the east by Nottinghamshire, from which it is separated by the Erewash. Its form is irregular; the greatest length is from north (from the point where the three counties of Derby, Chester, and York meet) to south (near Lullington on the Mease, a feeder of the Trent) 56 miles; the greatest breadth is from east (Holm Car Farm near Worksop, Notts) to west (near Chapel-en-le-Frith) 34 miles. The area of the county is estimated at 1010 square miles by Arrowsmith, 1028 square miles according to the statement subjoined to the *Abstract of the Answers and Returns* made in 1831 under the Population Act, or 1036 by taking the area of the different parishes. The population in 1831 was 237,170, or about 235,231, or 229 to a square mile, according to the computation of the area which we adopt. Derby, the county town, is on the Derwent, a feeder of the Trent, 114 or 115 miles N.N.W. of London in a straight line, or 126 miles by the road through St. Albans, &c. [DERBY.]

The county is comprehended between 52° 41' and 53° 30' N. lat. and 1° 10' and 2° 4' W. long.; the county town is in 52° 55' N. lat. and 1° 29' W. long. Besides the main part of the county bounded and situated as above, there is a small detached portion near the southern extremity, inclosed between the counties of Warwick, Leicester, and Stafford. It contains the villages and parishes of Measham, Stretton-in-the-Fields, and Wilsley, and the village and chapelry of Chilcote.*

Surface, Hydrography, and Communications.—The southern and south-eastern parts may be considered as on the whole flat, yet they have an easy ascent towards the north-western portion, which comprehends one of the most elevated and rugged districts in England. This part (which is commonly known by the name of the Peak) is occupied by a part of that range of high lands, which some geographers have designated the Penine chain, which separates the waters which flow into the sea on the eastern side of the island from those on the west side. This chain of mountains enters the county at or near its northern extremity, and the principal ridge runs in an irregular line S.S.W. till it enters Staffordshire a few miles S.W. of Buxton. Along this ridge are the following heights: Dean Head Stones, 539 feet high; Blakelow Stones, which Farey considers to be the highest point of the ridge and of the county generally; Kinderscout, which Farey considers to be inferior in height only to Blakelow Stones, and which is stated, we presume, in round numbers, to be 1800 feet high (*Phys. and Pol. Geog. of the Brit. Isles*, in *Lib. of Usef. Kn.*); and the northern and middle peaks of Axe Edge Hill, the southern peak being in Staffordshire. The northern or great summit of Axe Edge Hill has been stated to be 1875 feet above the level of the sea (Farey), but later observations have reduced it to 1751 feet; Lord's Seat, to the east of the principal ridge of the Penine chain, is 1751 feet high. This ridge divides the basin of the Mersey from that of the Trent, one of that large system of rivers which has the Humber for its æstuary. From this, the principal ridge of the chain, lateral ridges proceed, which bound the subordinate basins of the various affluents of the greater rivers mentioned already. One of these lateral ridges, branching from the principal ridge near Axe Edge Hill and running south-east, separates the basin of the Derwent from that of the Dove. The length of this ridge, following its windings, is estimated at 46 miles; but the length of a direct line between its extremities is not estimated at more than 35½ miles. The ridge, which forms the eastern boundary of the basin of the Derwent, and which extends in a winding course about 67 miles, does not wholly belong to Derbyshire. It branches off from the Penine chain, in Yorkshire, and approaching the border of that county towards Derbyshire, runs along the boundary, then enters Derbyshire, and proceeds in a south-eastern direction across the east moors of the county into Nottinghamshire.

* We give the above dimensions and the latitude and longitude of the extreme points from Arrowsmith's map. The length and breadth, as given in Farey's *Agricultural Survey* (where the detached portion of the county is included), are nearly the same as we have given; but the county is said to be comprehended between 52° 38' and 53° 27' N. lat., and between 1° 13' and 2° 34' W. long.

The first part of this ridge separates the waters of the Derwent from those of the Don, the part nearest to Nottinghamshire from those of the Rother, a feeder of the Don. In this ridge is the hill called Ox Stones, 1377 feet high, between Sheffield (Yorkshire) and Hathersage. Alport or Orpit hill, south-east of Wirksworth, is 980 feet high. It is said that from this eminence the Wrekin hill, near Shrewsbury, which is 50 miles distant, may be seen.

The Derbyshire highlands are intersected by narrow valleys or dales abounding with the most striking and picturesque scenery. We subjoin the following observations from Rhodes's *Peak Scenery* (8vo. edit., Lond., 1824). 'A more marked and obvious contrast in form and feature is scarcely to be met with in any part of the kingdom than the county of Derby presents. The more southern districts, though richly cultivated, are generally flat and monotonous in outline; to the picturesque traveller they are therefore comparatively of but little value: approaching its northern boundary it wears a more dignified aspect; here the hills, gradually assuming a wilder, a bolder, and a more majestic appearance, swell into mountains which, extending to the most elevated parts of the Peak, mingle their summits with the thin white clouds that often float around them.

'That part of Derbyshire, known by the name of the High Peak, is everywhere composed of a succession of hills, of a greater or lesser elevation, and intervening dales which play into each other in various directions. Throughout the whole the same general character prevails. A thin mossy verdure, often intermingled with grey barren rock, adorns their sides; and sometimes the interference of what Mr. Farey has denominated "indestructible limestone rubble" disfigures their steep acclivities. Yet even then a little brushwood occasionally breaks in to enliven and diversify the otherwise sterile scene. These remarks particularly apply to the minor dales of Derbyshire. Those which form the channels of the principal rivers are of a more elevated description, and possess, in an eminent degree, that variety of object, form, and colour, which is essential to picturesque beauty, sometimes united with a magnitude of parts where grandeur and sublimity preside in solitary stillness.

'Travellers, accustomed to well-wooded and highly cultivated scenes only, have frequently expressed a feeling bordering on disgust at the bleak and barren appearance of the mountains in the Peak of Derbyshire; but to the man whose taste is unsophisticated by a fondness for artificial adornments, they possess superior interest and impart more pleasing sensations. Remotely seen they are often beautiful. Many of their forms, even when near, are decidedly good; and in distance the features of rudeness, by which they are occasionally marked, are softened down into general and harmonious masses. The graceful and long-continued outline which they present, the breadth of light and shadow that spreads over their extended surfaces, and the delightful colouring with which they are sometimes invested, never fail to attract the attention of the picturesque traveller.' . . . 'Such are the appearances that often occur amongst the mountains of Derbyshire. Descending into the dales, especially those through which the Derwent, the Dove, and the Wye meander, the eye is enchanted with brilliant streams, well-cultivated meadows, luxuriant foliage, steep heathy hills, and craggy rocks, which administer to the delight of the traveller, and alternately soothe or elevate his mind as he moves along.'

The broadest and the deepest valleys are in the higher parts of the Peak. The picturesque beauty of the valleys is increased by the frequently precipitous character of the hills or rocks which bound them. The faces of these rocks rise up almost perpendicularly from the sides of the valleys, as may be observed near Castleton in the centre of the Peak, and near Stoney Middleton in the valley of the Derwent, where the Castle Rock rises to a vast height, and obtains its name from the singular and turret-like form which its craggy projections and points assume. Matlock High Tor, and other rocks in Matlock Dale, and the rocks which skirt some parts of the valley of the Dove, are of this precipitous character. In the smaller and narrower dales the projections of one side have corresponding recesses on the other.

The rivers of Derbyshire rise, for the most part, in the north-western and more elevated part of the county, and have a course toward the south or south-east. This is the case with the Derwent and its principal affluent the Wye, with the Dove, which is the boundary river of Staffordshire and Derbyshire, and those of its tributaries which belong to the

latter county. In the eastern part of the county about Chesterfield, which is separated from the other parts by the ridge of high land which bounds on the east side the valley of the Derwent, the direction of the stream that drains it (the Rother) is north-east. In the extreme north-west there are a few streams that flow westward into the Etherow or Goyt and so into the Mersey.

The Derwent rises in a place called 'the Trough,' on the border of Yorkshire and Derbyshire, where the principal ridge of the Penine chain enters the latter county, and has a S.S.E. course. Four or five miles from its source it receives a stream (the Westend river) of about the same length as itself, and about nine or ten miles from its source it is joined by the Ashop river, into which the Alport brook flows; and three miles lower down it receives the Noe or Now, from Hope Dale: all these tributaries join it on the west or right bank. From the junction of the Now the Derwent flows on through Chatsworth Park, twelve or thirteen miles, until it meets the Wye at Great Rowsley, not receiving in the way any accessions worth notice, except the brooks Burbadge and Barbrook, which fall into it on the left bank. The Wye rises near the Axe Edge Hill in the principal ridge of the Penine chain, and flows to the south-east through Miller's Dale and Monsal Dale and past the town of Bakewell into the Derwent: its whole course is more than twenty miles. From the junction of the Wye the Derwent flows on in the same direction (S.S.E.) as hitherto to Derby, and receives in its way the River Amber, about fourteen miles long, which joins it on the left bank above Belper, and the Ecclesburn from Wirksworth, about ten miles long, which joins it on the right bank. From the junction of the Wye to Derby is about twenty-five miles. Below Derby the river runs south-east with a sinuous course of about twelve miles into the Trent: this part of the river was made navigable some years since, but the navigation of it has been superseded by the cutting of the Derby canal. Its whole course is about sixty to sixty-five miles. 'In the space of forty miles, which includes the whole course of this river from the highest and wildest parts of the Peak to the town of Derby, scenery more richly diversified with beauty can hardly anywhere be found. Generally its banks are luxuriantly wooded: the oak, the elm, the alder, and the ash, flourish abundantly along its course; beneath the shade of whose united branches the Derwent is sometimes secluded from the eye of the traveller and becomes a companion for the ear alone; then, suddenly emerging into day, it spreads through a more open valley, or winding round some huge mountain or rocky precipice reflects their dark sides as it glides beneath. Sometimes this ever-varying and ever-pleasing stream precipitates its foaming waters over the rugged projections and rocky fragments that interrupt its way: again the ruffled waves subside and the current steals smoothly and gently through the vale, clear and almost imperceptible in motion.' (Rhodes's *Peak Scenery*.) The course of the Wye is generally through narrow dells with precipitous sides: it receives a small tributary, the Lathkill, just before it falls into the Derwent. The current of the Derwent is rapid, and its waters are said to be of a higher temperature than ordinary; in the summer season it is said the thermometer will stand in them at 66° Fahrenheit, and in severe weather it has been observed that the Derwent has not been frozen so early as the Trent, and has become open nearly a month earlier. (Pilkington's *Derbyshire*.)

The Dove rises on the border of Staffordshire and Derbyshire, in the slope of the Axe Edge hill, and is, throughout its course, the boundary between the counties. Its course is S.S.E., with little variation for about twenty miles, to Hanging Bridge by Ashbourne, just above and below which bridge it receives its first two Derbyshire tributaries of any consequence, viz., a stream which comes from the village of Parwick, about nine miles long, and the Schoo, which rises near Wirksworth, and flows by Ashbourne into the Dove, after a course of about ten miles. The Dove, in the upper part of its course, 'is one of the most beautiful streams that ever gave a charm to landscape: and while passing through the first and least picturesque division of the Dale (Dove Dale), the ear is soothed by its murmurings, and the eye delighted with the brilliancy of its waters—in some places it flows smoothly and solemnly along, but never slowly, in others its motion is rapid, impetuous, and even turbulent. The ash, the hazel, the slender osier, and the graceful birch, hung with honeysuckles and wild roses, dip their pensile

branches in the stream and break its surface into beauteous ripples. Huge fragments of stone, toppled from the rocks above, and partly covered with moss and plants that haunt and love the water, divide the stream into many currents; round these it bubbles in limpid rills that circle into innumerable eddies, which by their activity give life and motion to a numerous variety of aquatic plants and flowers that grow in the bed of the river: these wave their slender stems under the surface of the water, which, flowing over them like the transparent varnish of a picture, brings forth the most vivid colouring. Occasionally large stones are thrown across the stream, and interrupt its progress: over and amongst these it rushes rapidly into the pool below, forming in its frequent falls a series of fairy cascades, about which it foams and sparkles with a beauty and brilliancy peculiar to this lively and romantic river.' (Rhodes's *Peak Scenery*.) Below its junction with the Schoo, the Dove flows south-west for about three or four miles; then south for about seven more, receiving by the way the Churnet, its largest Staffordshire tributary; it then flows in a winding course E.S.E. for twelve or fourteen miles and falls into the Trent, just below Burton, receiving several streams, the longest of which rises near Atlow, between Ashbourn and Belper, and has a course of above fifteen miles. The whole course of the Dove may be estimated at from forty to forty-five miles. The waters of this river have a clear blue tint, deepening through various shades to a dark purple. It frequently overflows its banks in the spring; and the fertilizing effect of these floods has given rise to the distich—

'In April, Dove's flood
Is worth a king's good.'

Sometimes, however, the waters rise with such rapidity and violence as to be very destructive.

The Erewash rises in Nottinghamshire, near the village of Kirkby, and flowing W.S.W. for about three miles reaches the border of Derbyshire, and then flows, first S.W. and then S. by E., along the boundary of the two counties into the Trent. Its whole course is about twenty miles.

The Mease rises in Leicestershire, near Ashby de la Zouch, and flows first S.S.W., then W., and then N.N.W., into the Trent. Its course, which is about eighteen or twenty miles, is, for a short distance, in the detached portion of Derbyshire, partly on the border of the county, and partly beyond the border, in the counties of Leicester and Stafford.

These four rivers fall into the Trent, which crosses Derbyshire in a direction nearly north-east. It touches the border five or six miles north-east of Lichfield, just at the point where the Mease falls into it, and flows about ten miles N.N.W. along the border of Derbyshire and Staffordshire, past Burton upon Trent, in Staffordshire, until its junction with the Dove, after which it quits the border, runs nearly due east through Derbyshire for about eleven miles to the border of Leicestershire. It then turns E.N.E. and runs for about ten miles along the border separating Derbyshire from Leicestershire and Nottinghamshire, till its junction with the Erewash, after which it quits Derbyshire altogether. The Derwent falls into it about five miles above the junction of the Erewash. About thirty-one miles of the course of the Trent are thus upon or within the Derbyshire border. It is calculated (Farcy, *Agricultural Survey of Derbyshire*) that it receives the drainage of ten-thirteenths of the county, exclusive of the streams in the eastern part which flow into the Idle, one of the tributaries which joins the Trent in the lower part of its course. The Trent is navigable from Burton-upon-Trent, but in 1805 the navigation was given up by agreement with the proprietors of the Trent and Mersey canal, which runs by its side, and the navigation of the river now commences just at the junction of the Derwent.

The Goyt rises near Axe Edge, and flows N.N.W. along the border of Derbyshire and Cheshire, about fourteen miles, till its junction with the Etherow, which has a south-west course of about fifteen or sixteen miles chiefly on the border of the same two counties. The springs of the Etherow are in Yorkshire and Cheshire. The united stream of these two rivers flows into the Mersey at Stockport. They receive many small streams from the adjacent part (the High Peak) of Derbyshire.

The Rother rises in the East Moor, a mile or two east of Chatsworth Park, and flows eastward about eight miles to Chesterfield, where it turns to the north-east and flows into Yorkshire. About twenty-two or three miles of its course belong to Derbyshire. It joins the Don at Rotherham in

Yorkshire. The Dawley (ten miles long) is its only Derbyshire tributary that requires notice. This rises on the Nottinghamshire border and flows north past Bolsover.

The Sheaf, which joins the Don at Sheffield, the Wallin, the Poulter, and the Ryton, whose waters flow directly or ultimately into the Idle, rise in Derbyshire.

Derbyshire has several navigable canals and railroads. The canals are, 1, Grand Trunk, or the Trent and Mersey canal; 2, the Erewash canal; 3, the Derby canal; 4, the Cromford canal; 5, the Nutbrook canal; and 6, the Chesterfield canal. The Peak Forest and the Ashby-de-la-Zouch canals have a small portion of their extent just within the county, but rather belong, the former to Cheshire and the latter to Leicestershire. We shall not therefore notice them here.

1. The Trent and Mersey canal belongs to Derbyshire from its commencement in the river Trent, at Wilden Ferry (at the junction of the Derwent), to Monk's Bridge, where the canal is carried for a mile and a quarter over the flat meadows of the Dove valley on an embankment thirteen feet high, with aqueduct bridges over the Dove and one or two other streams, containing twenty-three arches of from twelve to fifteen feet span: twelve of these arches are over the main branch of the Dove. This canal was begun in 1766, and its whole extent is ninety-three miles. It extends through Derbyshire, Staffordshire, and Cheshire. Until the year 1785, men were employed in large gangs to draw the boats; now horses are universally used.

2. The Erewash canal commences in the Trent, midway between the junction of the Derwent and that of the Erewash river, and runs northward along the valley of the Erewash, first on the west and then on the east side of that river, and terminates in the Cromford canal at Langley Bridge: that part of its course which is on the east side of the Erewash belongs to Nottinghamshire. Its whole length is nearly eleven miles. It has aqueduct arches over the Nut brook and the Erewash river. It serves for the importation of corn, malt, and timber, and for the export of coal, limestone, iron, lead, and marble and other stone.

3. The Derby canal is described under the town of Derby. [DERBY.]

4. The Cromford canal commences in the Erewash canal at Langley Bridge, and runs northward to the Codnor Park Iron Works, following the valley of the Erewash, and having the first part of its course on the east side of that river in Nottinghamshire, and the latter part on the west side in Derbyshire. From Codnor it sends off a branch, two miles and a half or three miles long, along the valley of the Erewash, on the west or Derbyshire side of that river, to the village of Pinxton, while the main line of the canal turns westward to the valley of the Derwent, crossing the river Amber in its way; it then turns to the north-west, and follows the valley of the Derwent, first on the east and then on the west side of that river, to Cromford Bridge, where it terminates: the length of the canal is fifteen miles nearly. Between the valley of the Erewash and that of the Derwent this canal is carried through the higher ground by a tunnel more than a mile and a half long. The width of the canal in the tunnel is nine feet at the surface of the water; the crown of the arch is eight feet above the water. The tunnel is lined with brick, except where the perforated rock appeared capable of supporting itself. There are three aqueduct bridges on the line of this canal. One is over the Erewash; one, Bull Bridge aqueduct, which is over the Amber, is six hundred feet long and fifty feet high: the third aqueduct is over the Derwent, at Wigwell, and is six hundred feet long and thirty feet high; the span of the river arch is eighty feet. This canal is chiefly used for the conveyance of coals and coke; but lime and limestone, gritstone, ironstone, iron, lead, slate, timber, corn, &c., are carried on it. Besides the Pinxton cut already noticed, there is another small cut near the Derwent aqueduct, and there are several short railways which enable the coal-works, &c., on its line to communicate with the canal. A railway from Mansfield communicates with the Pinxton branch, and the Cromford and High Peak railway communicates with the main line of the canal near its termination at Cromford Bridge.

5. The Nutbrook canal commences at the collieries at Shipley, on the right of the road from Derby to Mansfield, and runs S.S.E. four miles and a half into the Erewash canal. Several railroads lead from the neighbouring col

lieries to the Nutbrook canal, the conveyance of coal being its chief object.

6. The Chesterfield canal commences in the tideway of the Trent, below Gainsborough, and has the greater part of its course in Nottinghamshire, and a small part in Yorkshire. It enters Derbyshire from the latter county near the village of Kilmarsh, in the valley of the Rother, and runs S. S. W. along that valley to Chesterfield. Its whole length is forty-six miles, of which about twelve are in Derbyshire. In the Derbyshire part of the canal are two aqueduct bridges, one over a brook at Renishaw furnace, and one over the Doolee or Dawley, a branch of the Rother, near Stavely: many railways communicate with it, and are intended to convey coal and iron from the collieries and iron works thereabout. This canal was opened A. D. 1777: its object is the exportation of coal, lime, lead, and iron; and the importation of corn, timber, &c.

The principal railroad is the Cromford and High Peak railroad. The others are of less importance; they are chiefly private property, and are designed to convey the produce of mines, collieries, and iron works to the various canals.

The Cromford and High Peak railroad commences at the Cromford canal, near its termination at Cromford, and runs in an irregular line north-west to the Peak Forest canal, which it joins at Whaley Bridge, three or four miles west of Chapel-en-le Frith. It passes near Wirksworth and Buxton. Its length is thirty-four miles nearly, and it has six inclined planes. The Act of Parliament for it was obtained in 1825: we are not aware whether the railroad is yet completed.

The great road from London to Manchester, Carlisle, and Glasgow, passes through this county. It enters Derbyshire at Cavendish Bridge, over the Trent, just above its junction with the Derwent, runs north-west through Derby and Ashbourne, and quits the county at Hanging Bridge, over the Dove. Two other roads to Manchester branch off from that just described; one at Ashbourne, which runs N. N. W. through Buxton, and quits the county at Whaley Bridge; another at Derby, which runs through Matlock, Bakewell, and Chapel-en-le-Frith. The road which connects Bristol and Birmingham with Sheffield and Leeds enters Derbyshire at Monk's Bridge, over the Dove, and runs northward by Derby, Chesterfield, and Dronfield, into Yorkshire. The road from London to Sheffield and Leeds enters the eastern side of the county from Nottinghamshire, and runs to Chesterfield, where it unites with the road just mentioned. A road from Sheffield to Manchester crosses the Peak through Hathersage, Castleton, and Chapel-en-le-Frith. The other roads are too numerous for us to notice.

Geology and Mineralogy.—That part of Derbyshire which lies south of a line drawn through Ashbourne, Duffield, and Sandiacre, is almost entirely occupied by the red marl or new red sandstone, a formation which overspreads so large a portion of the midland counties. There are indeed a few spots in which the magnesian limestone, which ordinarily underlies it, rises to the surface; and just on the Leicestershire border, near Ashby-de-la-Zouch, the coal-measures emerge from beneath it, and form one or two small detached coal-fields. In many parts, and especially along the valleys of the lower Derwent and the Trent, the red marl is covered by beds of gravel, and upon the gravel alluvial flats of loam or sandy loam, of from one to several feet in thickness, and without stones, are occasionally found. The strata of the red marl present considerable variety: among them are some micaceous gritstone beds, producing a good freestone; other strata are not concreted, but appear as sand, red, white, and yellow; others are more clayey, and from them bricks and tiles are made. The strata of the red marl formation are generally horizontal or nearly so. Several deposits of gypsum are found in this formation, and are quarried in several places, as at Darley Abbey [DERBY], in the tongue of land formed by the Derwent and the Trent, and in the southern extremity of the country. That gypsum, which is quite white, or only faintly streaked with red, is used by the potters of Staffordshire (as Plaster of Paris) for their moulds; some fine blocks are selected for the turners of alabaster ornaments, and the inferior sort is used by plasterers for ordinary purposes or for making the plaster floors often seen in this county. Some of the best land in or near Derbyshire lies on the red marl; in general however it is inclined to be too tenacious and cold.

This formation also occupies a very small portion of the county at its eastern extremity.

The newer magnesian or conglomerate limestone, which crops out from under the red marl of Nottinghamshire and skirts it on its western border, extends into the eastern part of Derbyshire, where it occupies the part east of a line drawn north and south through Bolsover. The thickness of this formation is probably 300 feet. The general colour is yellow, of various shades, from a bright gamboge to a light straw colour or white. Many of the beds have a granular texture, and cannot be calcined; they have generally passed with the inhabitants for gritstone rather than limestone. This limestone is quarried for building, also for flooring and staircases. Towards the bottom of the series are several beds of compact blue limestone, imbedded in blue clay, and abounding with shells. This blue limestone yields excellent lime: it is quarried at Bolsover, where also pipe clay is obtained: the pipe clay separates the limestone beds. The strata of the magnesian limestone form a better subsoil for arable than for grass land.

The coal-measures underlie the magnesian limestone and crop out from beneath it on the west. These coal-measures form part of that important coal-field which occupies a considerable part of the west riding of Yorkshire, and extends into Nottinghamshire and Derbyshire, being bounded on the east by the magnesian limestone, and on the south by the red marl. The strata range from north to south, and dip to the east. The Derbyshire portion of this coal-field is east of a line drawn from between Hathersage and Sheffield to Little Eaton, near Derby. There are twenty gritstone-beds, some of them of great thickness, and numerous strata of slate-clay, as shale, bind, and clunch: some of the shale-beds contain rounded or ovate masses, and even thin strata of argillaceous ironstone, with impressions of mussel shells, and coaly impressions of vegetables. A hard argillaceous rock called crowstone forms in some places the floor of the coal-beds. The number or order of the coal-seams is probably about thirty, varying in thickness from six inches to eleven feet: their aggregate thickness is about eighty feet: these dimensions can only be considered as approximate. Every variety of coal seems to be found in this field, hard stone coal, cannel, peacock, and caking coal. The coal-pits in Derbyshire are dispersed over the coal-field, and are very numerous, especially about Chesterfield and Alfreton, and in the district south and west of the Cromford and Erewash canals. There are coal-pits also in the small detached coal-fields on the Leicestershire border, noticed in speaking of the red marl, and coal is obtained between Ashbourne and Derby apparently by working through the red marl to the coal-measures which lie underneath them. The beds which lie between the seams of coal are worked for various purposes. The workings of the ironstone are generally begun at the surface, and pursued until they become dangerous from the loose nature of the stratum in which they lie: that ironstone which is marked with impressions of mussel shells (called the mussel band) is worked as an ornamental marble. From the gritstone-beds are quarried grindstones for cutlers: the binds, where they are hard and black, are used as black chalk; others, when decomposed, make good brick earth: the clunch is sometimes of that kind which is used for fire-bricks; where it crops out to the surface it becomes soft clay. Potters' clay, of various colours and qualities, occurs in this coal-field.

Millstone-grit and shale form a series of strata, having an aggregate thickness of about 870 feet; the millstone-grit, 360 feet thick, forming the upper part, and the shale and its associated rocks, 510 feet, the lower part of the formation. The millstone-grit ranges on three sides (viz., the east, north, and west,) of the carboniferous limestone, which we shall have presently to notice as occupying the central part of the county north of Ashbourne and Duffield: it occupies a tract between Duffield, Belper, and Wirksworth, on the west side of the Derwent, and forms the heights that bound the valley of that river on the east side up to its source. It occupies also the northern and western borders of the High Peak, and extends southward to Buxton, near which it passes into Staffordshire. The hills formed by it usually present a bold escarpment, crowned by rude piles of crags, exhibiting some of the wildest rock scenery of the district. The shale occupies a lower district between this and the carboniferous limestone, but in this lower tract are occasional insulated mountains, crowned with a cap of

millstone-grit. Kinderscout is one of these. The shale contains some alternating beds of fine-grained siliceous grit and nodules of ironstone; and it has some subjacent and apparently local beds of shale limestone, which afford a beautiful black marble.

Carboniferous or mountain limestone occupies the tract bounded on the south by the red marl, and on all other sides by the millstone-grit and shale just described. This limestone district is entirely comprehended in Derbyshire, except on the north-east, where it just passes over the Yorkshire boundary, and on the south-west, where it enters Staffordshire. There are one or two places in the southern part of the county where the limestone crops out. On the eastern side of the county the strata dip under the shale; but on the western side, by a great fault, the lowest bed of the limestone is elevated and brought into contact on the same level with the shale. The limestone is divided into four beds by three intervening beds of toadstone. The respective thickness of these limestone-beds (reckoning from the uppermost) is as follows:—first bed, 150 feet; second bed, 150 feet; third bed, 210 feet; fourth bed, at least 250 feet; aggregate at least 760, but in fact the thickness of the lower bed is not ascertained: it is only known that it extends 250 feet. In each bed of this limestone thin beds of clay are found, with imbedded masses of toadstone, and various organic remains. The lowest bed, which is the most esteemed by the lime-burners, has very few dark coloured strata; but in the three upper beds these are more common, and the second bed contains some very fine black strata, which are quarried as black marble. The upper bed is also quarried as marble, and contains white chert or china-stone, which is extensively used in the Staffordshire potteries. The beautiful fluor spar called 'Blue John,' from which vases and other ornaments are made, is found in a mountain of limestone.

The outcrop of the carboniferous limestone forms the lead district of Derbyshire. Numerous veins have been worked in it, chiefly for lead; but ores of zinc, iron, manganese, and copper, also occur. Lead ore is found occasionally in the toadstone which intervenes between the limestone-beds, but commonly the veins are cut off by the toadstone-beds. The veins which contain lead have generally a direction east and west; some of them approach the perpendicular (rake veins); others are nearly horizontal (pipe veins), and are rather beds of spar and ore, lying between the strata of limestone, and in most cases connected with the surface by a rake vein.

The limestone strata of Derbyshire are subject to very remarkable derangements or faults. They are characterized also by numerous caverns, and by the frequent engulfment of the streams by subterraneous courses termed swallow holes. The caverns appear to have been excavated wholly or chiefly by the agency of water.

The three toadstone-beds have an average thickness of 60 feet for the upper, and 75 feet for each of the lower, giving an aggregate of 210 feet; in parts however the thickness of the three amounts to above 250 feet. There are several varieties of the toadstone, which sometimes passes into ordinary basalt: among the substances inclosed are the quartz crystals locally termed Derbyshire diamonds.

Of the limestone caverns, the most remarkable is that now generally known as Peak's Hole, or the Devil's Cave, near Castleton. It is situated at the extremity of a deep and narrow rocky chasm in the valley in which Castleton stands, where craggy projections hide it from the traveller until he approaches pretty near. The entrance is a tolerably regular arch of about 40 feet high and above 100 wide, extending in length nearly 300 feet. This part is inhabited by poor people engaged in making twine and pack-thread, who have built their habitations and carry on their work under this natural shelter. At the end of this vestibule, as it may be termed, the arch contracts, and the visiter is obliged to stoop until he emerges into a spacious vault, called 'the bell house.' A second contraction, where the rock closes almost down upon the surface of a stream of water which occupies the passage, conducts to a third cavern, said to be 200 feet wide, and in some parts 120 feet high: this is succeeded by a series of cavernous chambers, at the extremity of the farthest of which the rocks close down upon the stream of water in such a way as to preclude all access to the caverns which are supposed to lie beyond. The water which thus obstructs

farther progress is a stream engulfed at a spot called Perry-foot, three miles from Castleton, on the Manchester road; it reappears at the innermost recess of the cavern, through the successive chambers of which it flows, and emerges into daylight at the entrance. After heavy rains this stream is so much swelled as to render it impossible to reach the farther part of the cavern. The whole length of Peak's Hole is variously estimated. Pilkington estimated it at 2250 feet, beside an additional chamber nearly 500 feet long. Elden Hole is a perpendicular chasm in a limestone rock near Castleton, more than 180 feet deep, with a sloping passage to an interior cavern or series of caverns. It is supposed that a second chasm of unknown depth descends from the bottom of this cavern. Another series of grottoes (Bagshaw Grottoes), extending about 2000 feet, adorned with stalactites, was first explored about the commencement of the present century. [For Pool's Hole, see Buxton.] There are several other caverns in the Peak.

The mineral springs of Derbyshire are numerous and important. The most celebrated warm springs are those at Buxton [Buxton] and Matlock. There are warm springs at Stoney Middleton, where it is supposed that the Romans established a bath. The temperature of the Middleton waters is 2° higher than that of the warmest springs at Matlock. The most celebrated of the sulphureous waters is at Kedleston Park, three miles north-west of Derby. They are valued for their antiscorbutic qualities. There are several chalybeate springs. For the ebbing and flowing well on the road from Buxton to Castleton, see Buxton.

Agriculture.—On the high hills and moors of Derbyshire the cultivation is not extended as it might be; and there are great tracts of rough pasture of no great value in their present state, which, with a moderate outlay, might be improved or converted into arable land, as has been done in similar situations in Scotland. In the valleys, or on the less abrupt hills, a very fertile red marly loam is frequently met with, which is productive of every kind of grain without any extraordinary tillage. Of this kind are the lands about Barton, Blount, and Ash, and in several places in the southern and eastern part of the county. The soil on the surface naturally partakes of the nature of the rocks which are found immediately below it; and where any particular stratum rises to the surface, or crops out, as it is called, the soil is chiefly made up of the same earthy substances, which have been more or less decomposed by the action of the air and mixed with vegetable matter. An account of the different soils is given in the Agricultural Report of the county, by Farey, of which the following table forms an epitome, distinguishing the strata from which they are formed and the number of acres in extent.

Gravelly soils	77,000 acres.
Red marl soil	81,000
Yellow limestone soil	21,580
Coal measure, upper part	30,000
" lower part	60,000
Grit stone and shale soils	160,500
Mineral limestone and toadstone } soils	51,500
Fourth limestone soil	40,500
Total surface	522,080 acres.

Most of these soils may be ranked among the clays and loams of various degrees of fertility, there being but a very small proportion of sandy soils in Derbyshire. Where these occur, they are mostly alluvial, apparently washed out of the loam and brought together by currents, or the decomposition of the grit and micaceous sandstone in the grit or limestone shale.

The climate of Derbyshire varies according to the situation and height of the land above the level of the sea. The quantity of rain that falls in the mountainous parts is much greater than that in the low country: at Chatsworth, for instance, the annual fall of rain is about 28·411, and at Derby 24·77 inches. In the valleys it differs little from the surrounding counties. The time of harvest is rather late in exposed situations, and is frequently much protracted by abundant rains in the month of October; it is therefore of great importance to sow as early as the season will permit, so as to have the corn ripe in time to gather it in before the autumnal rains.

The manner in which the soil is cultivated varies as much as its nature. Rich proprietors who have experienced bailiffs adopt all the new improvements, and their farms are well managed. There are also a few farmers who have some capital and manage their land well; but the majority are small farmers, who follow the routine of their forefathers, and have not the means, if they had the inclination, to make permanent improvements. A great many farms might be doubled in value by judicious draining, and lands made to produce turnips which now are thought too heavy and wet for this useful root. The pastures also might, in many places, be greatly improved by underdraining, and rendered much better adapted to feed sheep. A common obstacle to improvement is the want of leases; for although tenants are seldom removed if they pay their rents, and it is not unusual for a tenant from year to year, when he dies, to give possession of the farm to his widow or one of his children by a testamentary bequest, which is generally respected by the landlord, the rent may be raised, if the estate comes into other hands, and the money laid out on improvements by the tenant may be the cause of this rise. Tenants from year to year are therefore satisfied with a bare livelihood, and have no motive to improve their farms. Many farms are so small that they are scarcely superior to cottage tenures, and the occupiers have other means of gaining a livelihood besides their land. In the neighbourhood of Derby and other manufacturing towns, as also near the most productive mines, some small portions of land are neatly cultivated, in a great measure by the spade, and are consequently very productive. They are let at higher rents than the quality of the soil would otherwise warrant.

The course of cultivation on the best loams is generally that which begins with a summer fallow manured with lime for wheat, and succeeded by spring corn with or without clover or grass seeds. Some farmers have adopted the improved convertible system, and find the superiority of it in point of profit, uniting the advantages of a dairy with those of an arable farm. Spring wheat has been introduced instead of barley on the best soils, and the land is laid down with grass seeds in the first crop after the fallow, or the turnips, where these are introduced.

The wheat produced on the red land is good and heavy. On the poorer soils oats and barley are more certain and profitable crops. When the wheat has failed during the winter, and looks poor and thin in spring, it used to be a common practice to sow barley amongst it; the mixed produce was called *blend*, and ground to a coarse meal of which bread was made for the labourers. Spring wheat has been found a better substitute, and blend is now seldom met with. Haver cake made of oatmeal is still a common bread of the labourers, although wheaten bread is now very generally preferred.

Potatoes are raised in considerable quantities, both in garden plots, and in the fields, where they are planted in rows and moulded up with the plough. The produce on good loams well manured, especially on land ploughed up from grass, is very great. Six hundred bushels per acre is not thought a very extraordinary crop in very superior soils. They are given to cattle, as well as used for human food.

A large proportion of the lands is in permanent pastures, of which some are very rich. Derbyshire cheese is noted as of a good quality, and the best is often sold for Cheshire or Gloucester when made of the shape and colour of these cheeses. The common Derbyshire cheese is not generally coloured. It resembles some kinds of Dutch cheeses, and keeps well.

There are some very highly productive meadows along the course of the rivers in this county, but an improved system of embankment and irrigation is still wanting in many favourable situations. The meadows along the Dove and other rivers are from their situation very subject to sudden floods, which endanger the safety of the cattle grazing in them. To obviate this mounds of earth have been raised in many places, to which the cattle may fly for refuge; but a judicious embankment would be much more useful, by keeping the waters within proper channels, and would allow the admission of the water by flood-gates, when it is advantageous to the land.

When the upland pastures are mown for hay, they are also called meadows. Some of these are very rich, and will fatten the heaviest oxen; but the generality of the hilly

pastures are below the medium quality of pastures in England. They might be much improved by draining and weeding, which is seldom attended to.

There are many woods and coppices scattered through the country. There being no great demand for fire wood in a country abounding with coal, the coppices are allowed to grow for twenty or twenty-five years before they are cut, in order that the poles may acquire a considerable size, and be proper for supporting the roofs and sides of excavations in mines and coal-pits, or fit to make ladders of. A good coppice of twenty-five years' growth may be worth from 25*l.* to 50*l.* per acre to cut for the above purposes, leaving a sufficient number of trees and poles at each cutting to keep up the timber growing, which when felled will be worth as much as the underwood. Many young plantations have been made of late years, and are in a thriving state.

The horned cattle of Derbyshire have no peculiar character. The various improved breeds are met with in the richer pastures, and hardier animals on the mountains. The same may be said of the sheep. The sheep on the hills are similar to those found on the Cheviot Hills; in the valleys the Leicester and South Down breeds, and various crosses are generally preferred by the best farmers: but the quantity fattened is not so great as would be the case were the land better adapted for turnips.

The Derbyshire breed of horses is good, and many are bred in this county which are fitted for the carriage and the saddle, as well as for the farm, and form an important article in the profits of some of the larger farms.

There are numerous fairs in the county, as well as weekly markets: the principal fairs are the following:—Alfreton, July 31; November 22 (for horses and horned cattle). Ashburne, first Tuesday in January; February 13 (for horses and cattle); April 3; May 21; July 5 (do. and wool); August 16 (horses and cattle); October 10 (do.); St. Andrew's eve, or Saturday before (a considerable horse fair). *Ashover, April 25 and October 15 (cattle and sheep). Bakewell, Easter Monday; Whit Monday; August 26; Monday after October 10; and Monday after November 22. Belper, May 12; October 31 (cattle and sheep). Bolsover, Easter Monday. Chapel-en-le-Frith, Thursday before February 13; March 24 and 29; Thursday before Easter; April 30; Holy Thursday and three weeks after (cattle); July 7 (wool); Thursday before August 24 (sheep and cheese); Thursday after September 29; Thursday before November 11 (cattle). Chesterfield, January 25 or Saturday before (cattle); February 28 or Saturday before; first Saturday in April; May 4; July 5 (horses and cattle); September 25 (cheese, onions, &c.); last Saturday in November (cattle, sheep). Crich, Old Lady Day; Old Michaelmas Day. *Cubley, November 30 (fat hogs). *Darley Flash, May 13; October 27 (cattle and sheep). Derby, January 25; March 21 and 22 (cheese); Friday in Easter week (cattle); Friday after May day; Friday in Whitsun week; July 25 (cattle); September 27, 28, 29 (cheese); Friday before Old Michaelmas (cattle); October 18 (cheese). Dronfield, April 25 (cattle and cheese); August 11. *Duffield, March 1 (cattle). Higham, first Wednesday in the year. *Hope, May 12 and September 29 (cattle). *Matlock, February 25; May 9; July 16; October 24 (cattle and sheep). *Newhaven, September 11; October 30 (horses, cattle, and sheep, and a great holiday fair). *Plesley, May 6; October 29 (horses, cattle and sheep). *Ripley, Wednesday in Easter week; October 23 (horses and cattle). *Sawley, November 12 or Saturday before (foals). Tideswell, May 3 (cattle); second Wednesday in September; October 29 (cattle and sheep). Winster, Easter Monday. Wirksworth, Shrove Tuesday; May 12; September 8; October 4 and 5 (cattle).

Those places which are marked (*) have no weekly markets. Buxton and Cromford have a market, and no fairs.

Divisions, Towns, &c.—The divisions of Derbyshire for civil purposes were antiently called wapentakes; and of these divisions the 'Domesday Survey' mentions five: Scarvedale (Scarsdale), Hamestan (supposed to be what is now called the High Peak Hundred), Morlestan (Morleston), Walecross (supposed to be what is now the hundred of Repton and Gresley), and Apultre (Appletree); beside a district called Peché Fers (Peak Forest). A document of a somewhat later date (the 'Hundred Roll,' A.D. 1273) speaks of the wapentakes of Peck (Peak), Scarvedale,

Apeltre, Repindon (Repington or Repton), Greseleg (Gresley), Littlechurch (Litchurch), and Wirksworth (Wirksworth). Other records speak of the hundreds of Risley (Gresley?), and Sawley. The present division is as follows. The Wirksworth division is still called wapentake: the others are called hundreds.

I. High Peak (203,190 acres), North and North-West, and Central. Population in 1831, 47,485.

II. Wirksworth (73,880 acres), West and Central. Population in 1831, 23,287.

III. Scarsdale (144,750 acres), East and Central. Population in 1831, 53,582.

IV. Morleston and Litchurch (77,440 acres), South-East. Population in 1831, 61,779.

V. Appletree (108,170 acres), South-West and Central. Population in 1831, 32,483.

VI. Repington or Repton and Gresley (55,750 acres), South. Population in 1831, 18,554.

There is in Derbyshire only one parliamentary borough and market-town, Derby, on the Derwent (population in 1831, 23,627) [DERBY]; the other market-towns are sixteen. Of the following an account will be found under their respective articles:—Alfreton, between Derby and Chesterfield (population in 1831, 5691); Ashbourne, near the Dove (pop. 4884); Ashover, near the East Moor (pop. 3179); Bakewell, on the Wye, (pop. 9503); Buxton, near the head of the Wye (pop. 1211); Chapel-en-le-Frith, in the High Peak (pop. 3220); Chesterfield, on the Rother (pop. 10,688); and Wirksworth, between Derby and Matlock (pop. 7754). The population given above is that of the whole parish, except in the cases of Buxton, which is a chapelry of Bakewell parish, and the population of which is included in the statement given of the population of Bakewell, and of Derby, which is a borough containing parts of five parishes. Of the other towns, viz., Belper, Crich, Cromford, Dronfield, Heanor, Ilkeston, Tideswell, and Winster, and of the village of Matlock, we subjoin an account. We observe here, that Messrs. Lysons omit Dronfield from their list of market-towns, stating the market to have been discontinued; and Mr. Farey omits Ashover, Heanor, and Ilkeston. There are several other places which formerly had markets; those at Bolsover [BOLSOVER], Higham-in-Shirland, Hope, Matlock, Measham, and Sawley appear to have been discontinued within memory.

Belper is on the east bank of the Derwent, eight miles north of Derby. It is a township and chapelry, in the parish of Duffield, in Appletree hundred. The prosperity of Belper is of modern date, and is to be principally ascribed to the establishment of the cotton-works of Messrs. Strutt. It is now one of the most flourishing towns in Derbyshire. The older buildings form a very insignificant portion of the place, which consists chiefly of more modern and better erections. New buildings, with neat exteriors, flower-gardens, orchards, and plantations are fast spreading over the rising grounds about the town; and on the opposite side of the Derwent is Bridge Hill, the seat of G. B. Strutt, Esq. Gritstone, which the neighbourhood furnishes of excellent quality, is much used in building. The antient chapel, dedicated to St. John, being too small for the increased population of the place, a new church has been erected at an expense of nearly 12,000*l.*, defrayed partly by subscription and partly by a grant from the commissioners for building new churches. It stands on a bold elevation above the town, and from its situation and architecture, which is of the florid English style, is a great ornament to the place. It will accommodate 1500 persons, besides 300 children; and two-thirds of the sittings are free. The antient chapel is still used for evening lectures and for a school-room. There are places of worship for Unitarians (built in 1782, chiefly at the expense of Messrs. Strutt), Independents, General and Particular Baptists, and Wesleyan and Primitive Methodists. There is a stone bridge of three arches over the Derwent. The population of the chapelry of Belper in 1831 was 7890; half the males above twenty years of age are employed in manufactures. The chief establishments are those of Messrs. Strutt, who have four cotton-mills; and of Messrs. Ward, Brettle, and Ward, the most extensive hosiery manufacturers in the kingdom: they make both silk and cotton hose. The manufacture of nails, though thought to be declining, is still considerable. Seams of coal are worked with advantage about a mile from Belper. The market is

on Saturday. Coaches to or from London and Manchester, Birmingham and Sheffield, Nottingham and Manchester, pass through the town daily. Many of the tradesmen hold some land, and many persons, whose principal occupation is in trade or manufacture, are also partially occupied in agriculture.

The living of Belper is a perpetual curacy in the gift of the vicar of Duffield; the yearly value is 158*l.*, with a glebe-house. The state of education, according to the parliamentary return of 1833, was as follows:—1 infant school, 50 boys, 30 girls; 21 day-schools, 356 boys, 288 girls, all instructed at the cost of the parents; 7 Sunday-schools, 935 boys, 1027 girls: three of the Sunday-schools have lending libraries attached, and one of them (of above 600 children) is taught on the Lancasterian system. There are two neat almshouses for aged people, with a small endowment.

Crich is a market-town and parish, chiefly in the hundred of Morleston and Litchurch, but extending into the hundred of Scarsdale and the wapentake of Wirksworth. It is between the rivers Amber and Derwent, on the road from Alfreton to Wirksworth, five miles west of Alfreton and five east of Wirksworth, and about twelve miles north from Derby. The town is built on a considerable limestone hill that overlooks all the eminences round it. The church forms a very conspicuous object: it has a very tall spire. On a cliff near the village is a circular tower of modern erection, from which an extensive and beautiful prospect is obtained. The parish of Crich is divided into three parts: Crich township, 3770 acres, 2115 inhabitants, Litchurch and Morleston hundred; Wessington township, 1260 acres, 465 inhabitants, Scarsdale hundred; Tansley hamlet, 1150 acres, 507 inhabitants, Wirksworth wapentake. Total, 6180 acres, 3087 inhabitants. The inhabitants of the township of Crich, which includes several villages round the town, are chiefly engaged in working the lead-mines round, in getting limestone, which is excellent both for agriculture and building, and burning it to lime, in the manufacture of stockings, and in agriculture. There was antiently a market at Crich; but it had been discontinued. In the middle of the last century an attempt was made to revive it, but the attempt failed; in 1810 it was re-opened, and is still held. It is on Thursday, but is not much resorted to. There are two fairs in the year for cattle, pedlars' wares, &c.

The living of Crich is a vicarage, of the annual value of 98*l.*, with a glebe-house, in the gift of Sir Willoughby Dixie. There are places of worship in the parish for Wesleyan and Primitive Methodists and General Baptists.

Crich township contained in 1833 10 day-schools, in which were 115 boys and 112 girls; and 3 Sunday-schools, with 157 boys and 140 girls. In the other divisions of the parish were 1 day-school, with 36 boys in it, and 2 Sunday-schools, containing 137 boys and 92 girls.

Cromford is a market-town, township, and chapelry in the parish and hundred of Wirksworth, chiefly on the north bank of the Derwent. It is in a deep valley, enclosed on the north, south, and west by lofty limestone rocks. Cromford, like Belper, owes its prosperity to the cotton manufacture. The late Sir Richard Arkwright erected here a spacious cotton-mill on the north side of the Derwent; it is now occupied by Messrs. R. and P. Arkwright, who employ in these mills and those at Masson, a little higher up the Derwent, 800 persons. The houses and mills are chiefly built of gritstone. The church is a plain building, begun by the late Sir R. Arkwright and finished by his son; there was a more antient chapel, but it has been demolished many years.

The population of Cromford, in 1831, was 1291. Lead-mines are worked in the neighbourhood; lapis calaminaris is ground and prepared, and red lead manufactured. The Cromford canal terminates here; and the Cromford and High Peak railway joins the canal a short distance south of the town. The land in the township chiefly belongs to R. Arkwright, Esq.; every man employed at the mills capable of purchasing a cow has a piece of land sufficient to maintain it allotted to him. The market is on Saturday, and there are two fairs in the year. The education returns for 1833 give 1 infant school, 10 boys, 12 girls; 2 day-schools, 34 boys, 8 girls: all these are taught at the expense of their parents; 2 day and Sunday-schools, partly supported by P. Arkwright, Esq., 110 boys, 82 girls, who attend daily; 50 boys, 70 girls, who attend on Sundays.

Mr. Arkwright was building in 1833 two new school-rooms. There is a Methodist chapel. There are almshouses for six poor widows.

The living of Cromford is a perpetual curacy, of the annual value of 96*l.*, in the gift of R. Arkwright, Esq.

Dronfield is a market-town in the hundred of Scarsdale, on the road between Chesterfield and Sheffield, about 5½ miles from the former and 6½ from the latter, and 30 miles from Derby. The parish is extensive, containing 15,580 acres, or more than 24 square miles. It contains, beside Dronfield town (population in 1831, 1653), the townships of Little Barlow (pop. 58), Coal Aston (pop. 300), and Unstone (pop. 586); the chapelries of Holmsfield (pop. 499), and Dore (pop. 527), and the hamlet of Totley (pop. 351); the population of the whole parish was 3974. The parish church is beautifully situated on a hill on one side of the town. It has a fine tower and spire, chiefly in the decorated English style. The chancel has been very fine; it contains three rich stone stalls, the foliage of which is very beautiful; but the large east window has been deprived of its tracery. There are meeting-houses for Quakers, Wesleyans, and Independents.

There are some manufactures carried on at Dronfield, chiefly of iron goods, as cast iron chains and nails, axes, chisels, and other edge tools, common cutlery, and agricultural implements. The market, which Farey states to be much declined and which other authorities state to be discontinued, is on Thursday. There were in 1833 a well-endowed free-school for 60 boys and 20 girls; 3 boarding-schools (1 was for day-scholars also), with nearly 100 children; 6 day-schools, with nearly 200 children; 2 Sunday-schools, with 105 boys and 110 girls. The living is a vicarage, in the gift of the Lord Chancellor; yearly value 224*l.*, with a glebe-house.

The dependent districts of the parish have some manufactures similar to those of the town itself. They contained in 1833 6 day-schools, with 203 children: some of these schools have small endowments; 1 day and Sunday-school, with 60 day and 70 Sunday scholars, partly supported by an endowment; and 5 Sunday-schools, with 253 children. (*Education Returns for 1833.*) Dore (which appears to include Totley) is a perpetual curacy of the yearly value of 90*l.*, in the gift of Earl Fitzwilliam; Holmsfield is also a perpetual curacy of the yearly value of 97*l.*, with a glebe-house. Beauchief Abbey will be noticed presently.

Heanor is a market-town or village in the hundred of Morleston and Litchurch, on the road from Derby to Mansfield (Notts.), about nine miles from Derby. The parish is extensive, containing 6870 acres (or nearly 11 square miles), and a population (in 1831) of 5380 inhabitants, thus distributed:—Heanor township, 2672; Codnor and Loscow township, 1439; Shipley township, 632; and Codnor Castle and Park Liberty (extra-parochial), 637. Heanor is well situated for trade, the Erewash canal passing through the parish, and the neighbouring district having many coal-pits. There are manufactories for cotton goods, hosiery, and bobbin-net lace. The market, according to Messrs. Lysons, is on Wednesday; it is very small, and some authorities state that it has been discontinued. The living is a vicarage, of the yearly value of 109*l.*, in the gift of the Lord Chancellor. The education returns for 1833 comprehended 12 day-schools, with 234 children, and 5 Sunday-schools, with 824 children. There are Independent, Particular Baptist, and Wesleyan Methodist meeting-houses in the parish.

Ilkeston is in the hundred of Morleston and Litchurch, nine miles from Derby, on one of the roads to Nottingham, in the valley of the Erewash. The parish contains 2290 acres, and a population of 4446, a considerable portion of whom are engaged in manufactures or in the coal-pits in the neighbourhood. The church has a stone screen in the early English style of architecture, and three stalls in the chancel. The principal manufactures are of stockings and lace. A warm mineral spring, the properties of which are said to differ from those of all others in the kingdom, and to resemble those of the Seltzer water, has been lately discovered, and is coming rapidly into repute. The water, taken internally, and the baths, have been found efficacious in many complaints. The Erewash and the Nutbrook canals both pass through the parish. The market is held occasionally on Thursdays for fruit and vegetables. The living is a vicarage, of the annual value of 150*l.*, with a

glebe-house, in the gift of the duke of Rutland. The education returns for 1833 gave 17 day-schools (1 with a small endowment), containing 215 boys and 144 girls; and 7 Sunday-schools, with 427 boys and 414 girls, one of which has a lending library attached.

Matlock is in the wapentake of Wirksworth, on the banks of the river Derwent, 18 miles from Derby. The parish of Matlock contains 3960 acres, or more than 6 square miles. The five principal villages in it are Matlock, Matlock Baths, Matlock Bank, Harston or Hearthstone, and Ryber. The village of Matlock is antient, and chiefly inhabited by the persons employed in the neighbouring lead-mines and in the cotton manufacture. Matlock bath is nearly a mile and a half distant from the village, nearer to Derby, and is much resorted to by visitors, as much for the beauty of the situation as for the baths. There are three inns or hotels, several lodging-houses, and a museum, containing an excellent and tastefully-arranged collection of minerals, shells, and birds, and some articles of sculpture. There is a bridge over the Derwent at Matlock village. The church is a small edifice in the later English style of Gothic architecture. There are several Dissenting meeting-houses in the parish. The population of Matlock, in 1831, was 3262. The living is a rectory, of the annual value of 320*l.*, with a glebe-house, in the gift of the dean of Lincoln. The market formerly held at Matlock has been discontinued, but the place is well supplied with provisions. The education returns for 1833 comprehended 11 day-schools, 1 of them supported by endowment, and containing 30 boys, the other 10 containing 127 boys and 92 girls; 2 boarding-schools, with 12 boys and 24 girls; and 4 Sunday-schools, with 214 boys and 233 girls.

Matlock village and bath are in a dale which extends for two miles north and south, bounded on each side by steep rocks, whose naked sides rise to the height of nearly 300 feet; the summits are sometimes bare, sometimes covered with wood. Through this dale the Derwent flows, and its banks are lined with trees, except where the rocks approach, and rise almost perpendicularly from the water. Not far from Matlock is Willersley Castle, built by Sir R. Arkwright, and occupied by his descendants. The Matlock waters were brought into notice about 1698, when a bath was paved and built; but the place for a long time presented few conveniences. At later periods other springs were discovered, and new baths formed. The waters have a temperature of about 66° or 68° of Fahrenheit. They are considered to resemble the Bristol waters, and are recommended in bilious disorders, in phthisis, diabetes, and other complaints.

Tideswell is a market-town and parish in the High Peak hundred, about half a mile out of the road from Derby to Manchester by Chapel-en-le-Frith, nearly 35 miles from Derby. It is a small town situated in a bottom amid bleak naked hills: immediately round the town are some well-grown trees. The houses are low, irregularly situated, and ill built, and the general appearance of the place indicates the absence of wealth, comfort, and cleanliness. A rivulet of clear water runs through the town; the ebbing well, which is supposed to have given name to the town, has ceased to flow. The church is a fine building in the form of a cross, built about the middle of the fourteenth century, and principally in the decorated English style. The chancel is lighted by nine richly ornamented Gothic windows, and contains the monument of Robert Pursglove, suffragan bishop of Hull in the reign of Mary, and founder of a free-school and almshouses for twelve poor people at Tideswell. The tower of the church is at the west end: it is embattled, and has eight pinnacles. There was formerly a chapel of higher antiquity than the church, but the ruins were demolished some time since. There is a market on Wednesday. That part of the parish which contains the town had in 1831 a population of 1553, many of them are engaged in spinning and weaving cotton: previous to the introduction of the cotton manufacture, mining was the predominant occupation. The hamlets of Litton and Wheston, and the chapelry of Wormhill, which are comprehended in Tideswell parish, had in 1831 a population of 866, 75, and 313, respectively, making the aggregate population of the parish 2807. The living of Tideswell is a vicarage, in the peculiar jurisdiction of the dean and chapter of Litchfield, in whose gift it is: the annual value is 109*l.*, with a glebe-house. The perpetual curacy of Wormhill is of the annual value of 270*l.*, with a glebe-house, and is in the gift of trustees.

In 1833, beside the free-school (which contained 71 boys), there were four day-schools, containing about 60 boys and 100 girls; and two Sunday-schools, one supported by the church people, containing 45 to 50 boys; the other by the Methodists, containing 75 boys and 85 girls. In Wheston, Wormhill, and Litton, were four day-schools (one having a very small endowment), containing 70 to 80 children; and two Sunday-schools, containing about 100 children.

Winster is a market-town and chapelry in the parish of Youlgrave, in the hundred of High Peak. It lies between two roads which lead from Derby to Manchester, one by Wirksworth, the other by Ashbourne: by the former it is 24 miles from Derby, by the latter more than 25. This little town runs along the side of a steep eminence. The houses are built of limestone, and are partly thatched and partly covered with stone: they are intermingled with orchards and gardens. The church is small; it has preserved some features of Norman architecture, but it has been much altered. The market is on Saturday. The population of the chapelry in 1831 was 951: that of the whole parish (which is large, and extends into Wirksworth hundred) was 3681: the inhabitants are chiefly engaged in mining. The living of Youlgrave is a vicarage, in the gift of the duke of Devonshire, of the annual value of 214*l.*, with a glebe-house: the perpetual curacy of Winster is worth 104*l.* a year, and is in the gift of the freeholders. The chapelry contained in 1833 one infant school (with above 40 children); three day-schools (one partially endowed), with more than 120 children, and two Sunday-schools, containing 120 boys and 160 girls. There is a Wesleyan Methodist chapel. In the whole parish there were (beside the above) 9 day-schools (some of them partly supported by donation or endowment), with 233 children, and 7 Sunday-schools, with 524 children.

There are several barrows on the commons in the neighbourhood of Winster; in one which was opened in 1768 several antiquities were found.

Divisions for Ecclesiastical and Legal Purposes.—Derbyshire is in the diocese of Litchfield and Coventry: it constitutes the archdeaconry of Derby, which is subdivided into the six rural deaneries of Ashbourne, Castillar, Chesterfield, Derby, High Peak, and Repton. The deanery of High Peak has by some been called the archdeaconry of Derby, as though this were an ecclesiastical subdivision of the county. The number of parishes was given by Camden from Wolsey's list at 106; but later authorities make them more numerous; Pilkington states them at 116, their dependent chapelries at 69, and the extra-parochial chapels at 2: Messrs. Lysons state the parishes at 117; with 67 chapels, in 52 of which (49 parochial, 3 extra-parochial) the rites of marriage and sepulture are performed; many of these are frequently described as parish churches. The population returns contain a list of 140 parishes (beside 4 which are chiefly in other counties), 3 extra-parochial chapelries, and 46 dependent chapelries. The difference between these numbers and those given by Messrs. Lysons, may be partly accounted for by supposing several of the dependent chapelries to be entered as distinct parishes. Of the 117 parishes given by Messrs. Lysons, 50 are rectories, 58 vicarages, and 9 donatives, or perpetual curacies. Some of the Derbyshire parishes are very large, especially those in the High Peak hundred. Glossop parish contains 49,960 acres, or more than 79 square miles; Bakewell, 43,020, or above 67 square miles; Hope, 36,160, or above 56 square miles; and Hartington (in Wirksworth hundred), 24,160, or above 37 square miles: 9 other parishes in the county have from 10,000 to 20,000 acres, or from 15 to 30 square miles.

Derbyshire is in the midland circuit: the assizes and the quarter-sessions are held at Derby, except the Easter sessions, which are held at Chesterfield. Until the year 1569 this county and Nottinghamshire formed but one shrievalty. Until the reign of Henry III. the assizes for both counties were held at Nottingham: afterwards, until Derby was made a distinct shrievalty, they were held alternately at Nottingham and Derby.

Beside the ordinary county jurisdiction, Derby has some legal peculiarities, the relics of the institutions of former times. The hundred of Appletree and the honour of Tutbury form parts of the duchy of Lancaster. The courts of pleas of the duchy, commonly called the three weeks' courts, are held at Sudbury for the hundred of Appletree, and at Tutbury (which is in Staffordshire) for the honour of Tut-

bury. The jurisdiction of these courts extends to most places in the county: in them all debts and damages under forty shillings are recoverable. The Peveril court has likewise a very extensive jurisdiction; actions are brought in it for the recovery of small debts, and the proceedings are more expeditious and less expensive than in the courts at Westminster. This court is held at Basford, near Nottingham.

Derbyshire has some peculiar laws and regulations connected with the working of the lead-mines. These laws and regulations are of very high antiquity. The principal part of the county where lead ore is found in any considerable quantity is called 'the King's Field,' and comprehends nearly all the wapentake of Wirksworth and a considerable part of the High Peak hundred. 'The King's Field' has been from time immemorial let on lease. The lessees (of whom, when Pilkington wrote his account of Derbyshire, A.D. 1789, there were two) have each in his respective district a steward and barmasters. The steward presides as judge in the barmote courts, and, with twenty-four jurymen, chosen every half-year, determines all disputes which arise respecting the working of the mines. Debts incurred in working the mines are cognizable in these courts. These courts meet twice a year, or oftener if need be. The court for the High Peak district meets at Monyash, that for the wapentake district at the town of Wirksworth.

The office of the barmaster is principally to put miners into the possession of veins that they have discovered, and to collect the proportion of ore to which the lessee of the crown or the lord of the manor has a claim. When a miner has discovered a new vein of ore in 'the King's Field,' he may acquire a title to the exclusive possession of it, provided it be not in a garden, orchard, or high road, by a proper application to the barmaster of the liberty. Should the miner neglect to work the vein, the barmaster may, after a certain time, dispose of it to any one who is willing to try it.

There are four members of parliament returned for the county (two for the northern and two for the southern division), and two for the borough of Derby. The northern division of the county includes the hundreds of High Peak and Scarsdale, and part of the wapentake of Wirksworth: the principal place of election is Bakewell, and the polling stations are Bakewell, Chesterfield, and Chapel-en-le-Frith. The southern division includes the hundreds of Appletree, Morleston and Litchurch, and Repton and Gresley, and part of the wapentake of Wirksworth: the principal place of election is Derby, and the polling stations are Derby, Ashbourne, Wirksworth, Melbourne, and Belper.

History and Antiquities.—Before the Roman conquest Derbyshire appears to have been included in the territory of the Coritani, who, with the Cornavii, occupied the whole of the midland district from the Lincolnshire coast to the upper part of the Severn and the Dee. Upon the conquest of South Britain by the Romans, and its division into provinces, Derbyshire was included in the province of Flavia Caesariensis, not (as Pilkington, and after him, Messrs. Lysons state) of Britannia Prima.

The barren moors of this county abound in masses of gritstone, and single stones of vast size appearing above the surface: many tors (as Mock Beggar Hall, on Stanton moor, between Winster and Bakewell, Robin Hood's Mark, on Ashover common, &c.) and rocking stones have been found, and many rock-basins; but all these, to which it was once common to ascribe a druidical origin, seem referable, like the granite tors of Cornwall and Devonshire [CORNWALL], rather to natural causes. There are however circles of stones some upright stones, and tumuli or barrows of earth and stones, (called in Derbyshire, 'lows'), and some rude military works which appear to be memorials of the early inhabitants. The most remarkable of these monuments is the stone circle of Arbelows, or Arbor-low, two or three miles north-west of the town of Winster. An elliptical area of fifty-two yards by forty-six (having the greater diameter in a direction north and south), is enclosed by a ditch six yards broad, and an outer bank formed of the soil thrown out from the ditch, five yards high on the inside. In the inclosure there are openings or entrances on the north and south sides about fourteen yards wide, and adjacent to the southern entrance is a small mound or barrow. About thirty rough unhewn stones about five feet long by three broad, and one foot thick, lie round the inclosure, having their smaller ends pointing towards the centre: there is

reason to think these once stood obliquely on one end. About fourteen smaller stones are intermingled with these in an irregular manner, and there are three stones lying near the centre, one of which is larger than any other within the area. (Pilkington's *Derbyshire*.)

The antient British road, the Rykneld Street, and the Roman road, which usually coincided with it, cross this county in its whole extent from south-west to north-east, from the borders of Staffordshire to those of Yorkshire. The Rykneld Street enters Derbyshire where Monk's-bridge, over the Dove, now stands, and runs north-east in the direction of Little Chester, supposed to be the Roman station Derventio: the Rykneld Street is supposed to have passed the Derwent by a ford, perhaps at the town of Derby, the Roman road by a bridge a little higher up the river. [DERBY.] The two roads meet again near Derventio, and they may be traced in a direction nearly N.N.E. towards Chesterfield.

Chesterfield has been supposed to be a Roman station, the Lutudarum of Ravennas; and the first part of the name of the town (Chester—which, with its kindred forms, cester and caster, usually indicates the site of a Roman station) and the discovery of Roman coins there give probability to the supposition. The name of Lutudarum in an abridged form (LVR and LVRTVD) is stamped on three Roman pigs of lead (now in the British Museum) which have been found at different times near Matlock. (*Library of Entertaining Knowledge; Townley Gallery*, vol. ii., p. 288.)

A second Roman road has been traced from Brough in Hope Dale to Buxton, both of which are ascertained to have been Roman stations. At Brough three sides of the station, which was an oblong 310 feet by 270, are still perfect; and the foundations of a temple and another large building, with other antiquities, have been discovered. At Buxton several Roman baths have been discovered, and three of their roads at least, the one mentioned above, one from Derventio, and a third from Mancunium (Manchester), meet here,—a sufficient indication of the site of a station. It is conjectured that it was the Aquæ mentioned by Ravennas. Another Roman road, locally designated Long Lane, runs through the county from the river Dove at or near Rocester, which from its name was probably a station, to Derventio, and appears to have continued in the same line from thence into Nottinghamshire. Another Roman road, locally designated the Doctor's Gate, runs from the station of Melandra Castle, in Glossop parish, on the border of Cheshire, to Brough. There are some traces of other roads.

Derventio, now Little Chester [DERBY], appears to have been the most considerable Roman station in the county. The stations at Buxton, Brough in Hope Dale, and Melandra Castle in Glossop, have been mentioned. The last is on a moderate elevation at the meeting of two mountain streams: it is nearly square, 366 feet by 336; the ramparts and part of the ditch still remain, and the gates and the site of the Prætorium may be discovered: there are the foundations of many buildings on the side sloping to the water. It has been conjectured, but on uncertain grounds, that there were Roman stations at Parwich, between Buxton and Ashbourne, and at Pentrich, on the Rykneld Street, between Derventio and the modern Chesterfield: there are camps of the Roman form at both these places. The two camps, one on a hill above Castleton, and the other at Combe Moss, four miles from Buxton, may perhaps have been Roman summer camps.

Of Roman antiquities the most remarkable are an altar preserved at Haddon Hall, a silver plate found in Risley park, and the pigs of lead found near Matlock. These last are sufficient proofs of the Romans having wrought the lead mines of Derbyshire; and the number of their roads and stations indicates the importance they attached to the district. It is considered by some (Glover, *Hist. of Derbyshire*) that the working of the mines was anterior to the Roman conquest.

In the Saxon division of England, Derbyshire was comprehended in the kingdom of Mercia; and Repandun, or Repton, on the south bank of the Trent, was one of the royal residences. In the great invasion of England by the Danes in the time of Ethelred I. and Alfred [ALFRED], Derbyshire was overrun by them, and in the wars which Alfred and his successors maintained against them this county was frequently the scene of contest. The town of Derby was repeatedly taken and retaken. [DERBY.] At the Norman conquest considerable grants of land within the county were made to Henry de Ferrers, whose son Robert

was the first earl Ferrers. Another Robert, son of the first earl Ferrers, was created earl of Derby in 1138. William Peverel, a natural son of the Conqueror, received also considerable grants. He built the castle of the Peak; and he, or his son, is supposed to have built the original Bolsover Castle. [BOLSOVER.] The Peak castle is now an 'ill-shapen ruin,' situated on the verge of the rocky precipice that forms the roof of the Peak cavern at Castleton. It was small, but, from its situation, very strong. In the civil war in the reign of Henry II., Robert, earl Ferrers and Derby, who had supported prince Henry in his rebellion against his father, surrendered his castles of Duffield in Derbyshire and Tutbury in Staffordshire to the king. He was afterwards deprived of the earldom of Derby by Richard I., who bestowed it on his own brother John. In the civil war in the time of John, William earl Ferrers, who had obtained a new grant of the earldom of Derby, and who was one of the king's party, took the castles of the Peak and Bolsover, which had by this time passed out of the hands of the Peverel family, and were held by some of the party of the insurgent barons. In the reign of Henry III. the earl of Ferrers and Derby was one of the most active of the insurgent barons; but having been worsted and taken prisoner by Henry, the king's nephew, at the battle of Chesterfield, he was deprived of the earldom of Derby, with the vast possessions attached to it. These were afterwards given to Edmund, earl of Lancaster, son of Henry III., and thus eventually formed part of the domains of the duchy of Lancaster. No public events of interest are connected with Derbyshire until after the Reformation. The earldom of Derby, in connection with that of Lancaster, descended from prince Edmund to his son Thomas, who headed an insurrection of the barons against Piers Gavestone and Hugh de Spencer, the successive minions of Edward II.: the failure of this last enterprise led to the death of the earl, who was defeated and taken at Boroughbridge, and beheaded in Pontefract Castle in 1322. He was succeeded in his titles and possessions by his brother Henry, who supported queen Isabella and the earl of March (Roger Mortimer) in their successful attempt to dethrone Edward II. The earl was appointed head of the council of twelve bishops and peers, to whom the government was ostensibly intrusted. He died in 1344, and was succeeded in the earldoms of Lancaster and Derby by his son Henry, who had, with the title though not the possessions of earl of Derby, commanded the English forces in Guienne with signal success. This Henry died without male issue; his daughter Blanch married John of Gaunt, or Ghent, son of Edward III., who thus became earl of Lancaster and Derby, and transmitted these titles to his son, afterwards Henry IV. The earldom of Derby was conferred by Henry VII. upon his supporter, lord Stanley, in whose family it has ever since continued.

Derbyshire contains various relics of the middle ages, baronial, ecclesiastical, and monastic. Besides the Peak Castle, there are some remains of Codnor Castle, near Heanor, the antient residence of the Greys of Codnor: these remains are partly converted into a farm-house. Haddon Hall, the seat of the duke of Rutland, is on the north-east or left bank of the Wye, below Bakewell: it consists of two courts of irregular form, approaching to squares, surrounded by suites of apartments, and was evidently designed to have a domestic, not a military character. The chapel and the hall, the most antient parts, were erected in the earlier part of the fifteenth century, and no part of the edifice appears to be of later date than the reign of Henry VIII., except some of the interior fittings, which may be of the time of Elizabeth. The situation is beautiful, and the variety of the outline and the fine trees round the hall render it a very picturesque object. Hardwick Hall is a curious specimen of the style of domestic architecture in Elizabeth's reign, and has remained unaltered since the time of its erection; it is between Chesterfield and Mansfield, and belongs to the duke of Devonshire. Some of the furniture is perhaps older than the house itself, and was removed from the old hall, now in ruins, near the present mansion. There is at Hardwick some embroidery done by Mary, queen of Scots, who was imprisoned here and at Chatsworth and South Winfield for some time. South Winfield manor-house, near Alfreton, was built in the reign of Henry VI., and ruined in the civil wars of Charles I.: the remains present some beautiful features.

The churches of Derbyshire contain some very antient

portions. Repton church has under the chancel a very curious Norman or rather Saxon crypt, which there is reason to suppose was a part of the conventual church destroyed here by the Danes, A.D. 874. The rest of the church is of a later period; the architecture is varied, partly Norman, partly early English, and partly decorated English: the tower and spire, which are very lofty and of fine outline, are in the perpendicular English style. Melbourne church, near the border of Leicestershire, is a fine example of early Norman architecture, and is nearly in its original state. It has been conjectured, but without sufficient reason, to be as ancient as the seventh century. The desecrated chapel at Streetly is a Norman edifice, perfect, with the exception of the windows, which have been enlarged, and the roof: the ornaments are elaborate and well executed. The remains of early Gothic architecture in Derbyshire are few and by no means remarkable, except All Saints church at Derby [DERBY], and perhaps Ashbourne, Bakewell, Chesterfield, and Dronfield churches, the last of which has been noticed above. [ASHBOURNE, BAKEWELL, CHESTERFIELD.]

The monastic establishments of Derbyshire were neither large nor wealthy; there are very few remains of them. Some remains of Repton priory may be seen in the school at Repton and in the master's house. Repton has been noticed as a residence of the kings of Mercia. The priory was the place of sepulture for several of that royal race. After the old Saxon priory was destroyed by the Danes (see above), a monastery of Black (or Augustinian) canons was founded here by Maud, widow of Ranulph, second earl of Chester. Its yearly revenue at the dissolution was 167*l.* 18*s.* 2*d.* gross, or 118*l.* 8*s.* 6*d.* clear. There are at Yeaveley, four miles south of Ashbourne, some ruins of a chapel, formerly a preceptory of the order of St. John of Jerusalem. Of Dale Abbey, 6½ miles east of Derby, founded in 1204, for Premonstratensian Canons (clear yearly revenue, at the dissolution, 144*l.* 12*s.*), there are no remains, except the arch of the east window of the church. Beauchief Abbey, Norton, near Sheffield, is just within the boundary of Derbyshire: it was founded in 1183, for Premonstratensian or White Canons, by Robert Fitz Ranulph, lord of Alfreton, said to have been one of the murderers of Thomas à Becket, in expiation of whose murder the abbey was built, and to whom, when canonized, it was dedicated. Its yearly revenues, at the dissolution, were 157*l.* 10*s.* 2*d.* gross, or 126*l.* 3*s.* 4*d.* clear. The only part of the abbey now remaining is the west end of the conventual church, which is used as the chapel of the extra-parochial district of Beauchief. The architecture is plain, but the situation amidst woods and hills delightful. Dr. Pegge denies that Beauchief Abbey was erected in expiation of Becket's death, or that Fitz Ranulph had any connection with that deed.

The principal historical events connected with Derbyshire, since the Reformation, occurred during the civil war of Charles I. The county at first declared for the king,

who, after setting up his standard at Nottingham, marched to Derby; but it was soon brought over to the side of the parliament by the activity and influence of Sir John Gell, who, marching from Hull into Derbyshire (October, 1642), with a regiment of foot, only 140 men, raised 200 men at Chesterfield, and, proceeding to Derby, garrisoned that town. South Winfield manor-house was also garrisoned for the parliament. In November, 1642, Sir John drove Sir Francis Wortley and the king's forces from Wirksworth and the Peak, took Bretby House, south of the Trent, which had been fortified by the earl of Chesterfield, and defeated the royalists at Swarkestone bridge on the Trent. Next year (A.D. 1643) he took Bolsover Castle, which the earl of Newcastle had fortified for the king; and his brother, Colonel Gell, took Sutton House, near Chesterfield, which had been also garrisoned for the king by lord Deincourt. The earl of Newcastle is said, however, to have gained a victory over the parliamentarians near Chesterfield; he afterwards took South Winfield manor-house; and the royalists possessed themselves of the northern parts of the county. In March, 1644, there was an engagement on Egginton Heath, near the junction of the Dove with the Trent, in which the victory was doubtful. In the summer of the same year, Sir John Gell took South Winfield manor-house, and defeated the forces sent to relieve it; and General Crawford, another parliamentary commander, took Bolsover Castle and Stavely House. The king, after the battle of Naseby (A.D. 1645), retreated through Derbyshire into Yorkshire, gaining some advantages over Sir John Gell by the way. The subsequent events of the war were unimportant.

The advance of the young pretender to Derby in 1745 has been noticed in the account of the town of Derby. [DERBY.]

STATISTICS.—Population. Derbyshire is both an agricultural and manufacturing county; it ranked the twenty-ninth on the list of agricultural counties in 1811, but in 1831 it was the thirty-second, its manufacturing class having increased in a greater proportion than the agricultural class. Of 58,178 males twenty years of age and upwards, inhabitants of Derbyshire in 1831, 18,170 were engaged in agricultural pursuits, 10,593 of whom were labourers; and 8863 were employed in manufactures, or in making manufacturing machinery; there were likewise 10,897 labourers not employed as agriculturists. Of those employed in manufactures, about 1700 were engaged in the cotton-yarn and in the silk manufactures; 1400 in frame-work and twist; 1200 in cotton and silk hosiery; calico and ginghams, 600; lace and twist net, 450; tape, 60; paper, 40; and about 1400 not accurately classed, engaged in some of the above manufactures and in the preparation of dye colours, &c.; of these about 900 were employed in the town of Derby.

The following summary of the population taken at the enumeration of 1831, exhibits the number of inhabitants, &c., in each hundred of the county.

HUNDREDS, &c.	HOUSES.				OCCUPATIONS.			PERSONS.			Males twenty years of age.
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.	
Appletree . . .	6,143	6,542	23	180	2,778	2,689	1,075	16,212	16,271	32,483	7,924
High Peak . . .	8,911	9,335	115	565	2,619	4,246	2,470	23,654	23,831	47,485	11,832
Morleston and Lit-church . . .	7,322	7,754	36	184	2,036	3,154	2,564	18,877	19,275	38,152	9,182
Repton and Gresley . . .	3,664	3,826	26	69	1,728	1,384	714	9,259	9,295	18,554	4,531
Scarsdale . . .	10,552	11,008	91	384	2,841	3,762	4,405	27,072	26,510	53,582	13,324
Wirksworth . . .	4,664	4,784	22	275	1,267	1,873	1,644	11,397	11,890	23,287	5,605
Derby (borough) . . .	4,842	5,071	44	332	55	3,680	1,336	11,269	12,358	23,627	5,780
Totals . . .	46,098	48,320	357	1989	13,324	20,788	14,208	117,740	119,430	237,170	58,178

The population of Derbyshire at each of the four periods of—				
	Males.	Females.	Total.	Incr. per cent.
1801 was	79,401	81,741	161,142	
1811 „	91,494	93,993	185,487	15.10
1821 „	105,873	107,460	213,333	15.01
1831 „	117,740	119,430	237,170	11.22

Showing an increase between the first and last periods of 76,028, or not quite 47½ per cent., which is about 10 per cent. below the general rate of increase throughout England.

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of—

1801 were £54,459, which was 6s. 9d.	
1811 „ 93,963 „ „ 10s. 1d.	for each inhabitant.
1821 „ 86,756 „ „ 8s. 1d.	
1831 „ 78,717 „ „ 6s. 7d.	

The sum expended for the same purpose in the year ending 25th March, 1836, was 55,018*l.* 1*s.*, and assuming that the population had increased at the same rate of percentage since 1831, as in the ten years preceding that period, the above sum gives an average of 4*s.* 5*d.* for each inhabitant. All these averages are below those for the whole of England and Wales.

The sum raised in Derbyshire for poor's-rates, county-rate, and other local purposes, in the year ending 25th March, 1833, was 108,074*l.* 6*s.*, and was levied upon various descriptions of property as follows:—

	£	s.
On land	81,846	0
„ dwelling-houses	20,340	6
„ mills, factories, &c.	3,358	3
„ manorial profits, navigation, &c.	2,529	17
	<u>£108,074</u>	<u>6</u>

The amount expended was:—

For the relief of the poor	76,685	19
For suits of law, removal of paupers, &c.	4,211	11
For other purposes	30,226	2
	<u>£111,123</u>	<u>12</u>

In the returns made up for the subsequent years, the descriptions of property assessed for local purposes are not distinguished. In the years 1834, 1835, and 1836, 107,236*l.* 19*s.*, 93,392*l.* 19*s.*, and 80,578*l.* 17*s.*, were respectively raised, and the expenditure in the same years was as follow:—

	1834.	1835.	1836.
For the relief of the poor	£72,720 13	£62,885 15	£55,018 1
In suits of law, removals, &c.	4,163 8	3,422 10	2,981 17
Payment for or towards the county-rate	31,232 12	12,652 9	11,368 3
For all other purposes		13,818 7	11,890 14
Total money expended	<u>£108,116 13</u>	<u>92,779 1</u>	<u>81,197 15</u>

The saving effected in the sums expended for the relief of the poor in 1836, as compared with the expenditure of 1834, is therefore about 24½ per cent., and the saving effected upon the whole amount is rather more.

The number of turnpike trusts in Derbyshire is 40, as ascertained in 1834; the number of miles of road under their charge was 574; the annual income of that year, arising from the tolls and parish composition, was 38,920*l.* 10*s.* 2*d.*, and the annual expenditure 41,819*l.* 14*s.*

The county expenditure in 1834, exclusive of the relief for the poor, was 12,311*l.* 5*s.* 4*d.*, disbursed as follows:—

	£	s.	d.
Bridges, buildings, and repairs, &c.	778	10	0
Gaols, houses of correction, &c., and } maintaining prisoners, &c.	1,781	5	11
Shire halls and courts of justice— building, repairing, &c.	271	16	7
Prosecutions	1,690	3	5
Clerk of the peace	1,020	3	2
Conveyance of prisoners before trial	322	8	7
„ of transports	145	16	8
Apprehending and conveying vagrants	48	14	3
Constables—high and special	393	15	6
Coroner	244	13	0
Payment of debt, principal and interest	4,941	15	0
Miscellaneous	672	3	3

The number of persons charged with criminal offences, in the three septennial periods ending with 1820, 1827, and 1834, were 670,736, and 1314 respectively; making an average of 96 annually in the first period, of 105 in the second period, and of 189 in the third period. The numbers of persons tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect of which any costs were paid out of the county-rates, were 96, 82, and 68 respectively. Among the persons charged with offences, there were—

	1831.	1832.	1833.
Committed for felonies	85	73	63
„ misdemeanors	11	9	5

The total number of committals in each of the same years was 123, 107, and 82 respectively: of whom

	1831.	1832.	1833.
The number convicted was	82	80	64
„ acquitted	40	24	17
Discharged by proclamation	1	3	1

In 1835, at the assizes and sessions, 175 persons were charged with crimes in Derbyshire. Of these, 14 were charged with offences against the person, 7 of which were for common assaults; 17 for offences against property, committed with violence; 132 offences against property, committed without violence; 3 for uttering counterfeit coin; 7 for poaching; and 2 for misdemeanors. Of the whole number committed, 125 were convicted and 50 acquitted, or no bill found against them. Of those convicted, 21 were transported for life, 2 for 14 years, and 23 for 7 years; 19 were imprisoned for 1 year or above 6 months, and 58 for 6 months and under; 1 was fined, and 1 was discharged on sureties. Of the offenders, 155 were males and 20 were females. Among the offenders 60 could read and write, 56 could read only, 58 could neither read nor write, and the instruction of 1 could not be ascertained. The proportion of the offenders to the population was 1 in 1355.

The number of persons qualified to vote for the county members of Derbyshire is 12,040, being 1 in 19 of the whole population, and rather more than 1 in 5 of the male population twenty years of age and upwards, as taken in 1831. The expenses of the last election of the county members to parliament were to the inhabitants of the county 282*l.* 8*s.* 8*d.*, and were paid out of the general county-rate.

There are six savings-banks in this county. The number of depositors and amount of deposits on the 20th of November, 1832, 1833, 1834, and 1835 respectively, were:—

	1832.	1833.	1834.	1835.
Number of depositors	4829	5086	5380	5710
Amount of deposits	£172,581	177,470	187,253	201,927

The various sums placed in the savings-banks in 1834 and 1835 were distributed as under:—

	1834.		1835.	
	Depositors.	Deposits.	Depositors.	Deposits.
Not exceeding £20	2462	£19,382	2568	£21,933
„ 50	1796	54,310	1905	58,174
„ 100	696	47,851	794	53,843
„ 150	232	28,153	248	30,076
„ 200	145	24,786	142	24,555
Above 200	49	12,771	53	13,346
	5380	187,253	5710	201,927

Education.—The following particulars are obtained from the parliamentary inquiry on education, made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant Schools	46		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		497	
Females		498	
Sex not specified		411	
		<u>1,406</u>	

Daily Schools	730		
Number of children at such schools; ages from 4 to 14 years:—			
Males		10,989	
Females		8,723	
Sex not specified		3,390	
		<u>23,102</u>	
Schools	776		
Total of children under daily instruction			24,508

Sunday Schools	420		
Number of children at such schools; ages from 4 to 15 and 16 years:—			
Males		16,764	
Females		17,005	
Sex not specified		5,415	
		<u>39,184</u>	

Assuming that the population between 2 and 15 years has increased in the same uniform ratio from 1821 to 1834, as the whole population increased between 1821 and 1831, we find the approximate number living between those ages in Derbyshire, in 1834, was 81,982. A very large number of the children attend both daily and Sunday-schools; only 18 of the latter are in places where no other schools are kept; and 34 schools, in which there are 2058 children,

are both Sunday and daily schools. Duplicate entry is therefore known to have been created thus far, and probably in a much larger degree in other places; but this cannot be ascertained with exactness. In a few of the Sunday-schools there are some pupils receiving instruction who are beyond twenty years of age. Making allowance, therefore, for this uncertain data, we may conclude that perhaps not more than two-thirds of the population between 2 and 15 were receiving instruction at the period of the inquiry.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription		By payments from scholars.		Subscrip. and payment from scholars.	
	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.	Schls.	Scholars.
Infant Schools			1	12	34	900	11	494
Daily Schools	120	3632	23	646	533	14,395	54	4431
Sunday Schools	6	306	385	36,870	3	72	26	1936
Total...	126	3938	409	37,528	570	15,365	91	6861

The schools established by Dissenters, included in the above statement, are:—

	Schools.	Scholars.
Infant Schools	3	48
Daily „	9	287
Sunday „	166	18,485

The schools established since 1818 are:—

Infant and other daily schools	332	10,600
Sunday Schools	293	28,496

Thirty boarding-schools are daily included in the number of daily schools given above.

No schools in the county appear to be confined to the children of parents of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists, together with schools for children of Roman Catholic parents.

Lending libraries of books are attached to 90 schools in Derbyshire.

DEREHAM, EAST. [NORFOLK.]

DERG, LOUGH. [DONEGAL.]

DERHAM, the Rev. WILLIAM, D.D., an eminent English divine and philosopher, was born at Stowton, near Worcester, in November, 1657, and received his early education at Blockley in the same county. He was admitted of Trinity College, Oxford, in 1675. Having completed his academic studies, he was ordained, and in 1685 was instituted in the vicarage of Wargrave in Berkshire; and four years afterwards to the valuable rectory of Upminster in Essex, where he spent the remainder of his life. To this residence he was much attached; mainly because it gave him, by its contiguity to London, ample opportunities of associating with the scientific men of the metropolis. He was made canon of Windsor in 1716, and in 1730 he received from his university the diploma of D.D.

He devoted his attention, with great earnestness, to natural and experimental philosophy. He was enrolled a member of the Royal Society; and he contributed a considerable number of memoirs to its Transactions. These papers prove him to have been a man of indefatigable research and careful observation.

His first publication was the 'Artificial Clock-Maker,' which has gone through three or four editions, and is considered a useful manual even now. In 1711, 1712, and 1714, he preached those sermons at Boyle's Lecture which he afterwards expanded into the well-known works 'Physico-Theology' and 'Astro-Theology,' or a demonstration of the being and attributes of God from the works of creation and a survey of the heavens, enriched with valuable notes, and good engravings after drawings of his own. His next separate work was 'Christo-Theology,' or a demonstration of the divine authority of the Christian religion, being the substance of a sermon preached in the Abbey Church of Bath, in 1729. His last published work of his own was entitled 'A Defence of the Church's Right in Leasehold Estates,' written in answer to a work entitled 'An Inquiry into the Customary Estates and Tenant-rights of those who hold lands of the Church and other Foundations.' It was published in the name of Everard Fleetwood.

Dr. Derham also published some of the works of the naturalist Ray, of which he had procured the MSS., and to him the world is indebted for the publication of the philo-

sophical experiments of Dr. Hook. He also gave new editions of other of Ray's works, with valuable additions, original, and from the author's manuscripts; besides editing other works of value, amongst which was the 'Miscellanea Curiosa,' in 3 vols. small 8vo., a work of value even at this time.

A considerable number of his papers were printed in the Philosophical Transactions, from the 20th to the 39th volume inclusive, the principal of which are—

1. Experiments on Pendulums in vacuo.
2. Of an Instrument for finding the Meridian.
3. Experiments and Observations on the motion of Sound.
4. On the Migration of Birds.
5. On the Spots on the Sun from 1703 to 1711.
6. Observations on the Northern Lights, Oct. 8, 1726, and Oct. 13, 1728.
7. Tables of the Eclipses of Jupiter's Satellites.
8. Difference of Time in the Meridian of different places
9. On the Meteor called Ignis Fatuus.
10. The History of the Death-watch.
11. Meteorological Tables for several years.

Dr. Derham was of an ungainly appearance, small stature, and distorted form. He was not only the moral and religious benefactor of his parishioners, and of all those who came in his way, but he was likewise the physician of their bodies, and their pecuniary friend in all their difficulties. He lived beloved, and died lamented, at his rectory, in 1735, aged seventy-eight.

DERIVATION. The term *law of derivation* almost explains itself. Thus in finding the successive differential coefficients of a power of x , the law is,—to get the next differential coefficient, multiply the last by its exponent, and reduce the exponent by a unit. To treat of derivation in the most general sense would be to write a work on mathematical analysis, of which it may be said that most of its difficulties arise from want of sufficient knowledge of methods of derivation. But there is a more restricted use of the term, derived from the work of Arbogast [ARBOGAST], in which it applies to those laws of derivation which spring out of Taylor's Theorem. Hence the differential calculus, considered either in the manner of Lagrange, or in that of Arbogast, which is the treatment of a particular branch of the subject, is sometimes called the calculus of derivations. Lagrange himself calls the differential coefficient a derived function, the objection to which is the application of a generic term to one of its particular cases. For the successive logarithms, sines, &c., differences, integrals, &c., of a given function, are also functions derived from the original in different ways.

DERMATOBRANCHUS, a genus of Mollusks, established by M. Van-Hasselt and arranged by him among the *Nudibranchiata*. M. de Blainville thinks that its appropriate place is by the side of the *Scyllææ*. M. Rang in his manual, uncertain of its position, consigns it to the Genres non classés at the end of his book.

Generic character.—Animal depressed, semicircular, provided with a considerably large foot, and protected above by an enlarged mantle, rounded anteriorly, narrowed posteriorly, beset with elongated striæ or pustules, which are branchial. A pair of short, approximated, contractile tentacula situated between the head and the mantle. Eyes none? Three apertures on the right side of the body, the anterior opening near the head for the generative apparatus, the second for the vent, and the third for the urinary organ. *Locality*, Coast of Java.

DERMESTES. [DERMESTIDÆ.]

DERME/STIDÆ (Leach), a family of Coleopterous insects of the section Necrophaga (Mac Leay). Technical characters:—antennæ short, eleven-jointed, terminated by a compressed club, consisting of three or four joints; palpi small; mandibles short, thick, and generally dentated; head deeply inserted into the thorax; body generally oval, and more or less furnished with scales or hairs; legs short; tarsi five-jointed. The species of this family are for the most part of small size: their larvæ (at least those which are known) are covered with hair, and feed upon animal substances. The principal genera are *Dermestes*, *Ctesias*, *Megatoma*, and *Attagenus*.

The principal distinguishing characters of the genus *Dermestes* are:—antennæ scarcely differing in the sexes; the basal joint thick, the six following joints nearly of equal size, the eighth broader than long, the ninth and tenth very broad, and nearly of equal size, the eleventh also

broad, but not equal in size to the two preceding; palpi short and thick; body of an elongated oval shape.

Dermestes lardarius is about a quarter of an inch in length, and of a dull black colour; the basal half of each elytron is of an ashy tint, and has three black spots.

This insect is sometimes very abundant in houses in the neighbourhood of London and elsewhere, and when this is the case, is very destructive, since it will devour almost any animal substance, but we believe only in a dried state.

Dermestes vulpinus is about the same size as the last, from which it may be distinguished by the elytra being totally black, and the sides of the thorax and under parts of the body being covered with white scales.

This insect is brought over in great abundance in ships laden with hides. We have seen them in skins of quadrupeds, both from India and America. The larva is about half an inch in length, and covered with blackish brown hairs: like the perfect insect, it feeds upon dried skins, and hence, when abundant, is very destructive to this sort of property*.

Dermestes murinus is also about a quarter of an inch in length, and of a black colour; the upper parts of the head, thorax, and elytra, are mottled with scales of an ashy tint; the scutellum is of a fulvous colour; the under parts of the body are white.

This species is common in various parts of England, and is found in dried animals which have been suspended in the open air by gamekeepers and other persons.

In the genus *Ctesias* (Stephens), the two basal joints of the antennæ are thick; the six following are nearly of equal size, and rather slender; the ninth joint is rather long, and of an obconic form; the tenth joint is shorter than the last; and the terminal joint is conical. These three joints form together an elongated knob.

Ctesias serra is about an eighth of an inch in length, of a black colour, with yellowish antennæ. It is found under the loose bark of elm-trees. The larva is covered with long hairs†.

Genus *Megatoma* (Herbst). In this genus the two basal joints of the antennæ are thick; the four following are slender; the seventh and eighth joints are larger than the last mentioned, and the remainder form an elongated club; the terminal joint is twice as long as the others in the male, and but slightly elongated in the female.

Genus *Attagenus* (Latreille). Antennæ with the basal joint thick; the second less robust and shorter; the three following joints slender; the sixth, seventh, and eighth joints gradually increasing in size; the remainder forming a three-jointed club, of which the terminal joint is extremely long and almost cylindrical in the male, and of an elongated oval form in the female.

Attagenus Pellio is about an eighth of an inch in length, and of a black colour; the base of the antennæ is yellowish, and there is a round white spot in the middle of each elytron.

This insect is common in houses, and is very frequently found in quills, upon the pith of which it probably feeds.

DERMO'CHELYS. [TORTOISES.]

DERRY, a bishop's see in the archdiocese of Armagh in Ireland. The chapter consists of a dean, archdeacon, and three prebendaries. The diocese embraces the greater part of the county of Londonderry, a small portion of Antrim, a considerable portion of Tyrone, and a part of Donegal. Length from east to west 60 English miles; breadth from north to south 54½ do. It contains 55 parishes, constituting 57 benefices. In 1792 there were in this diocese 51 churches of the establishment. In 1834 the numbers were—churches of the establishment 62; Roman Catholic, 70; Presbyterian, 84; and other places of Protestant worship, 28. In the same year the gross population of the diocese was 367,041, of whom there were 50,350 members of the established church; 196,614 Roman Catholics; 118,339 Presbyterians; and 1,738 other Protestant dissenters; being in the proportion of rather more than five Protestants of whatever denomination to six Ro-

man Catholics. There were at the same time in the diocese 574 schools, educating 37,385 young persons, being in the proportion of 7²⁸/₁₀₀ per cent. of the entire population under daily instruction, in which respect Derry stands 5th among the 32 dioceses of Ireland. Of the above schools 74 were in connection with the national board of education.

Derry signifies 'a place of oaks.' In Pagan times, the eminence on which the city and cathedral of Derry now stand, was known as Derry-Calgaich, or the oak grove of Calgach. The place began to be known in ecclesiastical history towards the end of the sixth century, when Columba came hither from Iona, and founded a church. From this period down to the plantation of Ulster it was called from him Derry-Columbkil, and was famous for its abbey and religious foundations. There is no trace of a bishopric here till the time of the council of Rath-breasil in 1118, when this district seems to have been included in the ancient diocese of Ardstraw or Rathlury. The distinct episcopal see of Derry was not however established till 1158, when Flahertach O'Brolchain, the then abbot of the monastery, was raised to the dignity of bishop, by decree of the council of Brighmac-Taidhg, over which the celebrated primate Gelasius, who is said to have been the chief instrument in establishing the discipline and influence of the church of Rome in Ireland, presided.

This see remained unreformed, together with those of Raphoe and Clogher, down to the time of the plantation of Ulster. The first Protestant bishop was George Montgomery, nominated to the succession in 1603. Among the succeeding Protestant prelates may be mentioned Bramhall, the able partisan of Strafford; King, the author of the 'State of the Protestants in Ireland under king James's government;' Nicholson the compiler of the English, Scotch, and Irish Historical Libraries; and Hervey, earl of Bristol, distinguished for his zealous patriotism and munificent patronage of the arts. Derry is the richest bishop's see in Ireland. By the return of the Commissioners of Ecclesiastical Revenue and Patronage in Ireland, it appears that on an average of three years ending 1st December, 1831, the net yearly income of this see amounted to 12,159*l.* 3*s.* 6*d.* By the 3rd & 4th Wm. IV. c. 64, this is curtailed by 4160*l.* per annum during the life of the present bishop, which reduction is to be increased to the further amount of 6160*l.* per annum during the lives of his successors. [LONDONDERRY.] There is a very full account of the history and antiquities of this see in the first part of a 'Memoir of the Ordnance Survey of Ireland,' 4to. Hodges and Smith, Dublin, 1837.

DERWENT, DERWENTWATER. [BORROWDALE, CUMBERLAND.]

DERWENT. [DERBYSHIRE.]

DERWISH is a Persian word, properly an adjective, which signifies poor, indigent; as a substantive it is used to denote a religious mendicant, hermit, or any one who retires from social life in order to devote himself entirely to religious contemplation. It is synonymous with the Arabic *Fakîr*, and both expressions are chiefly employed to designate a class of persons in Mohammedan countries nearly corresponding to the different orders of monks among the Christians. It would be difficult to determine the age to which the origin of the Derwishes is to be referred. From time almost immemorial, pious men in the East, as elsewhere, seem to have thought it meritorious to renounce the enjoyment of temporal things and the ties of domestic and social relations, and to live in poverty and solitude for the purpose of turning their thoughts altogether towards spiritual matters. Oriental tradition makes the order of hermits as ancient not only as St. John the Baptist or Elias, but even as the time of Seth. In the *Koran* poverty is recommended as meritorious; and Mohammed is reported to have said, 'See that ye come poor before God, for the poor shall have the first place in his mansion.' Jâmi, the well-known Persian poet, is the author of an esteemed work on the lives of the *Sûfis*, or Mohammedan mystics. In the introduction, he divides those 'who seek the future life' into four classes: the *Zâhids*, who being filled with religious faith, look down with contempt on the life on earth, which they consider as imperfect and miserable; the *Fakîrs*, who renounce the world, hoping that they will thus have less to account for, that they shall be hereafter recompensed for present privations, and that their minds will by poverty be rendered fitter for the exercise of virtue; the *Khâdîms*, who attach themselves as servants to persons

* In the 14th vol. of the Linnean Transactions, page 586, will be found a notice of the occurrence of several specimens of this insect, and also of another beetle (*Necrobia violacea*) in the Egyptian mummy; and in the Transactions of the Entomological Society (vol. i. 'Journal of Proceedings,' page 11) the Rev. F. W. Hope describes several species of Coleopterous insects which had been found in the heads of Egyptian mummies. They are as follows:—*Necrobia Mumiarum*, *Dermestes pollinctus*, *Dermestes Roei*, and *Dermestes elongatus*:—accompanying these insects there were also found some fragments of a species of *Pimelia*—probably the *P. spinulosa*.

† A figure of this larva will be found in the 'Entomological Magazine,' vol. ii., plate 10.

conspicuous for their sanctity; and the *Abids*, who hope to merit future reward by entirely devoting themselves to religious exercises. Among the Turks several orders of Fakirs or Derwishes exist. The principal one is that of the *Maulavîs*, founded by the celebrated Persian poet Jelâl-eddîn Rûmî, who died A.D. 1262. The Derwishes of this order have a great monastery at Galata, and another at Iconium. Their demeanour is very humble, and their robes are extremely coarse: besides the fast during the month of Ramazan, they keep a weekly fast on every Thursday. It is part of their religious practices to turn round with great velocity to the sound of a pipe, and when the music ceases to stop at once, without showing symptoms of giddiness. They may leave their order, and are then released from their vow of chastity, and permitted to marry. Some amuse the common people by tricks of legerdemain, or apply themselves to the practice of sorcery and conjurations. They are notorious for their fondness of intoxicating liquors and of opium. They have convents in nearly all Mohammedan countries, which serve the travelling pilgrims of this order as inns. The order of the *Rufâîs*, founded A.D. 1182, by Sheikh Ahmed Rufâî, is distinguished by the strange excesses of self-mortification to which its members are carried by their fanaticism. In their weekly assemblies in the hall of their convents, some are always selected to hold a red hot piece of iron between their teeth till it becomes cool, while the others make deep incisions in their bodies with sharp-edged instruments. Another class of Derwishes is that of the *Calenders*. They are distinguished by the singularity of their dress, which is sometimes made of party-coloured cloth, and sometimes consists of a tiger's or sheep's hide, or is made of iron. Frequently the Calenders go about half naked, with their skin painted red or black. They wear feathers in their ears, and have their heads covered with hats or turbans of a fanciful shape. They generally carry in their hands a stick or a hatchet, or sometimes a drawn sword. In their girdles they carry a plate or bowl, which they hold out to receive charities. They often visit coffee-houses and other places of public resort to preach, and act as if they were inspired. In their religious opinions the greatest variety prevails. The Derwishes do not seem to be much respected by the public: they are considered as hypocrites, who have assumed a sanctimonious appearance in order to have a pretext for idleness, and who clandestinely indulge in the grossest licentiousness. All Derwishes, with the exception of the *Maulavîs*, are allowed to marry; but they are obliged to sleep one or two nights in the convent of their order. (Chardin's *Travels*, ed. Amsterdam, 1735, 4to., vol. ii., pp. 269-97; Paul Rycaut, *The present state of the Ottoman Empire*, &c., London, 1668, fol., p. 135 et seq.; D'Herbelot, *Bibl. Cr.*, art. *Derviche* and *Fakir*; Mouradgea d'Ohsson, *Tableau de l'Empire Ottoman*.)

DERZHAVIN, GABRIEL ROMANOVITCH, the most distinguished lyric poet Russia has yet produced, being acknowledged superior to Lomonosov himself, was born at Kasan, July 3, 1743. After completing his education in the Gymnasium of that city, he commenced the usual military career, 1760, by entering the engineer service, in which the attention he gave to his mathematical studies soon obtained for him promotion. He did not, however, rise to the grade of lieutenant until 1774, when he was sent with his corps to reduce the rebel Pugachev, on which occasion he displayed much bravery and address. He continued to advance in military promotion; but quitted the service, on being appointed a counsellor of state, in 1784, and afterwards governor of Olonetz and of Tambov successively. In 1791, Catherine bestowed on him the office of secretary of state; in 1793 he was called to the senate, and the following year was made president of the college of commerce. Various other appointments followed, the last of which was that of minister of justice, in 1802; from which he retired the following year, on a full pay pension. This he lived to enjoy for a considerable period, as he did not die until 1816, three days after he had entered his 74th year.

Such a career, both military and official, by no means an unusual one with the literary men of Russia, however uncongenial it may appear to us, did not prevent his cultivating the Muses during some of the most busy portion of it; for the finest of his odes were produced at that period. Pre-eminent among these, and perhaps unrivalled by any similar composition in any other language, is his 'Oda Bog' o: Address to the Deity,' a piece full of sublimity

both as regards the ideas and expressions. Indeed, elevation of conception and nobleness of sentiment, no less than great energy and mastery of language, are striking characteristics of Derzhavin's poetry; and if occasionally more negligent than Lomonosov, it is because he is borne away by the intensity of his feelings. On the other hand, he manifests greater freshness, originality, and richness than his predecessor; and while he enchants by the eloquence of his lyre, he elevates and purifies the soul by the moral grandeur of his strains. In the art of which he was so profound a master, he has shown himself no less able as a theorist and critic by his treatise on Lyric Poetry, printed in the 'Tchenie v Besedæ,' a miscellany edited by a society for the cultivation of the Russian language. Besides the essay just mentioned, he wrote some other works in prose, among which is a 'Topographical Description of the Government of Tambov.' A collection of his works was first printed in 1810, in four volumes; to which was added another, shortly before his death.

DESAGUADERO. [BOLIVIA, vol. v., p. 85.]

DESAGULIERS, JOHN THEOPHILUS, D.D. was brought to England while an infant by his father the Rev. John Desaguliers, a French Protestant refugee, after the Revocation of the Edict of Nantes. He was born at Rochelle, on the 12th of March, 1683.

His early education he owed to the instructions of his father, who appears to have been a very respectable scholar and sound divine, and at an early age he was sent to Christ Church, Oxford. In 1702, being then only nineteen, he succeeded Dr. Keil in reading lectures on Experimental Philosophy at Hart Hall; and he ever afterwards prosecuted his physical researches with great earnestness and success. Upon his marriage in 1712, he settled in London, where he was the first that introduced the reading of lectures to the public on natural and experimental philosophy. This he did with great and continued reputation to the end of his life, which terminated in 1749, in the sixty-sixth year of his age. The highest personages were attracted by the novelty of this mode of teaching; and he was several times honoured with reading his lectures before the king and royal family.

In 1714 Desaguliers was elected a Fellow of the Royal Society, of which he proved a valuable member. The duke of Chandos appointed him his chaplain, and presented him with the living of Edgware, near his seat at Cannons; and he was afterwards made chaplain to the prince of Wales.

From some causes which are not well understood, Desaguliers appears to have fallen into a state of great destitution;—we say appears, for the authority on which the assertion rests has, so far as we know, neither received collateral proof nor denial. He certainly did remove to lodgings over the Piazza in Covent Garden, in which he continued his lectures; but the lines of the poet Cawthorn are the only authority on which the statement of extreme indigence rests:—

Here poor neglected Desaguliers fell!
How he who taught two gracious kings to view
All Boyle ennobled, and all Bacon knew,
Died in a cell, without a friend to save,
Without a guinea, and without a grave!

If this statement be true, he must either have been the dupe of others to a great extent, or singularly improvident in his own affairs; as besides his emoluments from his lecturing, he held two church livings.

Desaguliers left a family. One of his sons was an officer in the royal artillery, being Colonel of one of four battalions of which that regiment was composed. Colonel Desaguliers, who was a great favourite with George the Third, died in 1775; and if any of his descendants be living, they may possibly be able to clear up this otherwise inexplicable circumstance.

The separate writings of Desaguliers contain an elegant exposition of the more popular portions of experimental philosophy. His mind was more fitted for the popular and the practical than for the profounder inquiries into those branches of science; and for the geometrical method of investigation than for the higher and then new calculus which has since so completely changed the whole current of research. His works are—

1. A Course of Lectures on Experimental Philosophy, 2 vols. 4to. 1734.

2. An Edition of Dr. David Gregory's Elements of Catoptrics and Dioptrics, with an Appendix on Reflecting Telescopes, 8vo. 1735.

This Appendix contains some original letters between Sir

Isaac Newton and Mr. James Gregory relative to these telescopes, which are worthy of attention.

3. A Translation of the curious, valuable, and little known Treatise on Perspective, by S'Gravesande, 8vo.

4. A Translation of S'Gravesande's Natural Philosophy, 2 vols. 4to. 1747.

5. A Translation of Nieuwentyt's Religious Philosopher, 3 vols. 8vo.

Several respectable papers by Desaguliers are inserted in the Philosophical Transactions from 1714 to 1743.

DESCANT, in music—(the etymology is very doubtful)—signifies, in strict language, a melody or air, extemporized on a *canto-fermo* [PLAIN CHANT], or, in other words, an enlarging *all'improvviso*, i. e. unpremeditatedly, on a given subject, which subject, sung by another voice, or other voices, forms the accompaniment of the descant. Thus the term was understood in the eleventh and twelfth centuries, both by Franchinus and John de Muris; but afterwards it became synonymous with counterpoint. [COUNTERPOINT.] It has now however fallen into disuse, and is not to be met with, except in dictionaries, in any writer of modern date.

DESCARTES, RENE', was born at La Haye, in Touraine, on the 31st of March, 1596, and died at Stockholm on the 11th of February, 1650, before he had completed his fifty-fourth year.

Descartes was of noble descent, being a younger son of a councillor in the parliament of Rennes. He is one of the many instances of great delicacy of constitution being combined with the highest order of mind. His early education was among the Jesuits, who had, shortly previous, established one of their seminaries or colleges in the neighbourhood of his father's residence at La Flèche; and though Descartes was one of those men who would have educated himself in the absence of all instruction, there can be no doubt that the system adopted in the colleges of the Jesuits was much better calculated to develop the peculiar powers of the students than any other which has ever prevailed in modern Europe.

During his course in the college of La Flèche he contracted a friendship with Marsenne, which continued to the end of the life of that distinguished monk, and this circumstance doubtless tended much to increase the attachment of Descartes to mathematical and metaphysical studies. Algebra was at this time studied by few, and it had acquired but little extent and power as an instrument of investigation; whilst geometry, as it was then cultivated, tended too much to run into a mere deduction of isolated but curious and difficult propositions, without much regard to the general principles upon which their analysis and synthesis depended, or to the nature of the fundamental principles upon which geometrical reasoning was ultimately founded. The comparative novelty of the algebraic methods would give a charm to the study in a mind constituted like that of Descartes; and an examination of its first principles, and the operations of the mind in the actual development of the truths of geometry, would be more likely to arrest his active mind than the mere deduction of curious but necessary consequences. It is easy to conceive that his reading and course of study in the college would be somewhat desultory, and that he often depended more upon his own innate power for going through his exercises than upon the lectures of the professor, or the books which were put into his hands. This character in Descartes was properly appreciated by his friends and tutors. He formed the determination of renouncing all books, and endeavouring to efface from his mind the knowledge which he had been taught, so as to only employ the power which he had gained by the discipline of his college, to investigate the fundamental principles of human knowledge *ab initio*. Still this can hardly be thought to be a suddenly-formed resolution. Even allowing this to have been a plan gradually formed, the execution of it was a Herculean task; nor was it unattended with personal danger, as the contemporary history of Galileo sufficiently proves. Considering therefore that Descartes was at this time only nineteen years of age, the whole circumstance is one without a parallel in intellectual history.

Descartes wisely abstained from publishing his views at this time, or indeed his mathematical discoveries, of which there is some probability that he was in possession at this early age; but conformably with the fashion of the age among men of his social and political condition, he engaged in the profession of arms. He served first as a volun-

teer in the army of Holland, and then in that of the duke of Bavaria; and he was present at the battle of Prague in 1620, in which he conducted himself with great intrepidity. There is no profession more inimical to the study of abstract science than that of arms, and hence Descartes soon abandoned it for the purer and more honourable career to which his previous studies and native ardour of mind were so admirably adapted. But even during his attachment to the camp he did not neglect his mathematical and philosophical inquiries. It is believed to have been during his stay at Breda that Descartes composed his *Compendium Musicae*, although it was not printed till after his death. Another circumstance indicative of his devotion to geometry is also narrated in connection with the same campaign, and occurring also at Breda. One day, seeing a group of people surrounding a placard, he found it written in Flemish, a language which he did not understand, and therefore applied to one of the bystanders for an explanation. This person chanced to be Beckmann, principal of the college of Dort, who, wondering that a young soldier should take any interest in geometry—the placard being in keeping with the practice of the age, a problem proposed as a challenge—explained the problem to him, but is said to have displayed something of the collegiate pedantry which was then so common. Descartes however promised him a solution, which he sent to the principal early next morning.

The cause of his resigning his commission is said to have been disgust at the atrocities which he witnessed in Hungary: but it is more likely that his object was to see the world under a different aspect, which his travelling as a private individual would enable him to do. He visited in succession Holland, France, Italy, and Switzerland, and stayed some time in Venice and Rome. It has often created surprise, that while in Italy he did not visit Galileo; and the cause which has been usually assigned was his jealousy of the fame of that father of physics, an assumption which there is reason to fear is too well founded. His repulsive conduct towards Fermat, whose overtures of an amicable correspondence he so long rejected with an appearance of disdain, seems also to intimate the wish of Descartes to reign alone in the circle of his associates, and in the philosophic world altogether.

After completing his travels, Descartes determined to devote his attention exclusively to philosophical and mathematical inquiries; and his ambition was to renovate the whole circle of the sciences. He sold a portion of his patrimony in France, and retired to Holland, where he imagined he should be more free to follow his inclination without the interruptions to which his celebrity in his own country rendered him perpetually liable. His writings, however, involved him in much controversy; and the vivacity and dogmatism of his temper often led him to treat in a somewhat supercilious manner the greatest men amongst his contemporaries. The personal courage of Descartes was great; and, unlike many valiant writers, he was valiant in the most trying personal dangers.

The fame of Descartes was very great, even in his lifetime: and that not only among the learned, but in the highest circles of society in every part of Europe. When, therefore, the church rose in arms against the heresy of his philosophy, and he was subjected to much persecution and some danger, he accepted the invitation of Christina, queen of Sweden, who offered him an asylum and complete protection from the bigoted hostility of his enemies. He was treated by the queen with the greatest distinction, and was released from the observance of any of the humiliating usages so generally exacted by sovereigns of those times from all whom they admitted into their presence. The queen, however, probably from the love of differing from every one else, chose to pursue her studies with Descartes at five o'clock in the morning; and as his health was always far from robust, and now peculiarly delicate, the rigour of the climate, and the unseasonable hour, which formed such a striking contrast with those to which he had been many years habituated, brought on pulmonary disease, of which he very soon expired, in the fifty-fourth year of his age. The queen wished to inter him with great honour in Sweden; but the French ambassador interposed, and his remains were conveyed for sepulture amongst his countrymen in Paris. Thus fell one of the greatest men of his age, a victim to the absurd caprice of the royal patron under whose auspices he had taken shelter from the persecutions of the church.

Probably there is scarcely a name on record, the bearer of which has given a greater impulse to mathematical and philosophical inquiry than Descartes. As a mathematician he actually published but little; and yet in every subject which he treated he has opened a new field of investigation. The simple application of the notation of indices to algebraical powers has totally new modelled the whole science of algebra. The very simple conception of expressing the fundamental property of curve lines and curve surfaces by equations between the co-ordinates, has led to an almost total supersedence of the geometry of the antients. The view which he proposed of the constitution of equations is contested as to originality; but admitting, as we do, his claims on this head to be open to dispute, the writings and discoveries of Descartes have laid the foundation for such a change in the general character of mathematical science as renders it extremely difficult for those who have not given very great attention to the older writers to follow the course of reasoning which they employed. The claims of Descartes, however, to the originality of his views on the composition of equations and the relation between their roots and their co-efficients, are discussed under the name of his competitor. [HARRIOTT.]

His speculations in physics have often been ridiculed by subsequent writers, and there can be no doubt that they are sufficiently absurd. Still many reasons may be urged in mitigation of that ridicule, and even of the more temperate censure which careful and judicious historians of science have dealt out upon the intellectual character of Descartes. It ought especially to be observed that the theories of all his predecessors were mere empirical conjectures respecting the places and paths of the celestial bodies; they constituted, so to speak, the plane astronomy of those times, in contradistinction to the physical astronomy of ours. Those paths were not deduced as the necessary effect of any given *law of force*, but as the result of some fixed and unalterable system of machinery invisible to us, and directly under either the control of original accident or the original will of God. Innumerable hypotheses of the nature of this machinery had been framed before the time of Descartes; and he, being dissatisfied with all others, adopted that of an ethereal fluid, which was continually revolving round a centre, like the water in a vortex. This was not so unnatural to a philosopher living before the 'Principia' made its appearance as it would be absurd in any one to contend for it now. We have indeed been too much in the habit of measuring the philosophical sanity of Descartes by the knowledge of our own times—a most unjust test to be applied to the intellectual efforts of any man by his successors. We ought rather to look to what he did accomplish under all the difficulties of his position in respect to the then state of science than measure him by the efforts which were attended with no beneficial result. He was, however, the first who brought optical science under the command of mathematics, by the discovery of the law of the refraction of the ordinary ray through diaphanous bodies. He determined the law itself, but not as the result of any law of force. This was a later discovery: but Descartes led the way.

His inquiries in the positive philosophy were distinguished by great acuteness and subtlety; and though his theory has not in a direct form obtained many advocates in this country, it has in reality been the foundation of most of the sects which have since risen in every part of Europe. Differing as these systems do so very widely at first sight, this may be considered a paradoxical assertion. It is nevertheless the fact. For its proofs the reader is referred to the articles PHILOSOPHY (POSITIVE), METAPHYSICS, and PHILOSOPHY OF THE HUMAN MIND.

The works of Descartes have been collected and reprinted three times. The first—

1. Opera Omnia, 1690-1701, 9 vols. 4to. Amst.
2. Opera Omnia, 1713, also 9 vols. 4to. Amst.
3. Opera Omnia, 1724-26, in 13 vols. 12mo. Paris.

DESCENT, in English law (from *discent*, Norman French, and so written in our older law books), may be defined the act of law by which on the death of the owner of an inheritance, without making any disposition thereof, it is cast upon another as an heir. Inheritance is sometimes used in the same sense, though it rather signifies that which is, or may be, inherited, or taken by descent. (Littleton, sect. 9.)

1. The law of inheritance with respect to descents which have taken place since, or shall take place after the 1st of January, 1834, is now regulated by the Act 3 & 4 Wm. IV.

c. 106, but some notice of what the law was before that time is necessary; since it is the constant practice, in the investigation of titles to property, to inquire what happened fifty or sixty years ago.

2. The death of the owner of the inheritance is the occasion of the descent of it. In his lifetime, there can be no descent, and therefore no heir, though there may be an 'heir apparent,' or 'heir presumptive;' an heir apparent being he who must be the heir, if he lives till the inheritance descends; an heir presumptive, he who may be forestalled by the birth of a nearer heir.

3. The person who dies must be at his death owner of the inheritance, or no descent of it will then take place.

4. Inheritances, *hereditaments*, things which may be *inherited* or *taken by descent*, are various. The principal of these is the crown, the descent of which differs in one material respect from that of a private inheritance, inasmuch as where there are no sons of the king, an elder daughter takes the whole of the inheritance, in exclusion of the younger sisters. Again, dignities and honours, as baronies and other peerages, are descendible, according to the limitations contained in the patents by which they were created. If created by summons in the first instance, they are called dignities in fee, and are descendible to females. [BARONY.] Finally, all the subjects of real property and all annuities, offices, and whatever other things may be 'held in fee,' are 'descendible,' and this whether they are in possession, reversion, remainder, or expectancy. So are all rights and titles to things that may be held in fee, and the expectancy of an heir apparent or presumptive. There are also 'descendible freeholds,' that is, estates created by leases for lives, which, though not estates in fee, may during their continuance be inherited as if they were. It has been already noticed [CHATTEL] that the large class of things called chattels are not generally the subject of descent, but that some of them are.

5. Upon the death of the owner, the law casts the inheritance upon the heir, without any act done by him, or price paid for his acquisition: in both these respects, the present law of descent differs from the old feudal customs from which it is derived. According to the old feudal customs, upon the death of the tenant of a fee, the lord of whom it was held was entitled to take and retain it till the heir, for whom proclamation was made, appeared, and paid a sum of money called a relief [RELIEF] as the consideration for his admission into the tenancy; whereupon 'seisin' or possession was given him, and he took the 'oath of fealty' [FEALTY], and if the tenancy was by 'knight's service,' 'did homage' [HOMAGE] also to the lord. All this was more like a new donation, than the present quiet succession of an heir. The descent of copyholds, however, is still regulated much in the manner described. The heir was not however formerly, to the same extent as now, subject to the charges and debts of the deceased tenant, in respect of the property descended [ASSERS]; and he had also an advantage, which is much insisted and commented upon by the old law writers, though its value is not so apparent to us. The descent of an inheritance, of which the rightful owner had been *disseised* or unlawfully dispossessed, prevented him from making an *entry* upon the heir of the disseisor, or bringing an action of ejectment, the right to maintain which is founded upon the right to make an actual entry, and left him only 'a writ of right,' or other real action, for the recovery of his property. One whole chapter of Littleton's *Tenures* is taken up with treating of descents which 'toll' (take away) entries, but a late Act (3 & 4 Wm. IV. c. 27) prevents descents from having any longer this effect. The present law of descents qualifies materially in one respect the title of the heir to the inheritance descended. Though it makes him as completely the owner of it as if he had purchased it, as to right of enjoyment and power of alienation, it does not allow it at his death to descend as if he had purchased it, but, on the contrary, declares that it shall descend as if he had never had it. Such at least is the new law (s. 1, 2 of the Act). The heir of an inheritance must be always the heir of the last 'purchaser' of it, that is, of the last person who acquired the property 'otherwise than by descent, or than by an escheat partition or inclosure, by the effect of which the land shall have become part of, or descendible, in the same manner as other land acquired by descent.' The practical importance of this rule cannot be understood without knowing who the person is who in any case is designated by the law as the 'heir' to another.

As to descents in fee simple, the fundamental rule is, that any person *of kin* to another, that is, descended from the same ancestor, however distant, may be his heir, but that no person connected with him by marriage or affinity only [AFFINITY], can inherit to him. If the son inherits to the father, his mother cannot succeed to him, for though she may be heir to the son, she cannot be heir to the father, from whom, and not from the son, 'the descent is to be traced.' On the other hand, if the father inherits to the son, the mother may succeed to him, for though she cannot be the heir of the father, she may be the heir of the son. The fee, fief, or feud, which may thus now descend to the kindred of the purchaser *in infinitum*, was once nothing more than a life interest given to the tenant or holder of it in consideration of the military services to be rendered by the latter to the donor. [ALLODIUM.] The fee was afterwards permitted to descend to the issue of the original grantee, and in process of time to his *collateral* heirs. This was only effected by means of a fiction; for so firmly settled was the notion that 'the blood' (descending) alone of the purchaser or original grantee could be allowed to inherit, that the feudal law was never brought to allow collateral heirs, as such, to be heirs. But when a feud was granted *ut antiquum*, that is, to be held by the donee as if it had descended to him from some remote unknown ancestor, then the law permitted collateral relations however distant, that is, relations descended from any common ancestor, however remote, to inherit. For it was not known how far distant the ancestor was who was supposed to have been the purchaser, nor who he was, and it was sufficient that the heir *might* be a descendant of his. (See for the early history of inheritable fiefs, Robertson's *Charles V.*, Sullivan's *Lectures*, Wright's *Tenures*, Gilbert on *Tenures* by Watkins, Butler's *Coke upon Littleton* 191. a. n. where there is an excellent comparison of the Roman and feudal laws of inheritance.)

While the law however went thus far, it did not, for reasons which some writers have attempted to explain, allow the *lineal* ancestors of the purchaser of the *quasi* ancient feud to inherit it, nor his relations by the half blood, that is, persons descended not from the same father *and* mother as the purchaser, or any lineal ancestor of his, but from one of them only. Still further exclusions followed from the rule which was afterwards established, that the heir of the fee must be the heir of the person last *seised* or possessed of it, as well as a kinsman of the whole blood to the actual purchaser. Among the practical consequences of this rule were the following: that if the child of the actual purchaser inherited to him, and became seised, the purchaser's child by another wife could not succeed, because only half brother to the person last seised; and that if the father's brother inherited to the son and became seised, the mother's brother could not succeed, because only related by marriage to the person last seised. All these exclusions and the fictions of the ancient feuds are done away with by the new act, the effect of which is, as before said, to admit among the heirs of the purchaser all his kindred, both of the whole and the half blood, and notwithstanding any previous descent to any heir of his. This it does by enacting that every lineal ancestor shall be capable of being heir to any of his issue (s. 6); that any person related to the purchaser by the half blood shall be capable of being his heir (s. 9), and that in every case descent shall be traced from the purchaser (s. 2). Still, however, the wife or her relations cannot inherit to the husband, nor the husband or his relations to the wife. But the hardship of these exclusions is at least mitigated by the law of dower and curtesy, which must be read together with the law of descent as one law. It remains to show in what order the kindred of the purchaser inherit. The old law on this subject is reduced by Blackstone to seven rules, which have been generally copied by later writers; but the new act so interferes with them, and they seem, besides, to be so capable of being simplified, that we shall propose instead of them the following rules, which, it is believed, embody the present law on this subject. We shall follow Blackstone's plan of stating the rules in the order in which they may have to be applied in searching for an heir.

1. The child (if any) of the last owner deceased is the heir of the purchaser. Thus not only is the child of the purchaser his heir upon his death, but if any other heir of the purchaser dies after having inherited, *his* child is the heir of the purchaser.

2. The person through whom another must trace his

descent from the purchaser is (if living) the heir before that other person. Now, bearing in mind that descent is always to be traced lineally, that is, either from parent to child, grandchild, &c., or *vice versa*, it follows that the purchaser's child must, if living, inherit before *his* child the brother before the nephew, the father before the brother or the grandfather, &c. If the purchaser had a child who died in his lifetime, leaving a child, that child is the purchaser's heir, according to rule 1: for the expectancy of the child of being next heir to the purchaser descended upon his death, to his child, as being his next heir, who consequently becomes, upon the purchaser's death, *his* heir. It is surprising that this plain and certainly true explanation of the effect in question has been overlooked by all the writers on the law of descents, who lay down a separate rule (the 4th of Blackstone's) to account for it.

According to these rules 1 and 2, the effect of which is very much to simplify the course of descents, when an inheritance has once got into a *line*, it will keep continually descending in that line, till the line ends; and then it will only go back as far as the head of the next line, which springs from the line in which it has been descending, and will descend in that line, and so on; thus:

3. Of persons related to each other, as brothers and sisters, the males inherit before the females: the former successively in order of birth; the latter altogether in equal shares, being therefore called *coparceners*. (This rule is qualified by rule 5.) Hence the sons of the purchaser inherit before the daughters, and first his eldest son, then his second, &c.; then all his daughters together. It makes no difference whether the coparceners are related to each other by the whole or the half blood. This division among females often causes the minute splitting of inheritances, as thus:

According to the custom of *gavelkind*, all the sons, and in default of sons, all the daughters inherit together as coparceners. As to the custom of *Borough English*, see that title.

4. Every male ancestor inherits before any female one. This is qualified by rule 2. (See s. 7 of the new act.) Hence the father takes before the mother, &c., but not the mother's father before her, for he claims through her.

5. Those who are relations by the half blood to the purchaser inherit next after their brothers and sisters, who are relations by the whole blood to the purchaser. (Qualified by rule 4 and 2; see s. 9 of the new act.) What the half blood is has been already explained. Thus (by an

exception to rule 3) the half brother takes after the whole sister, and the half sister does not share with the whole sister. The like is true of half uncles, &c. According to this rule 5, however, the purchaser's brother of the half blood on the part of the *mother* does not take next after his brother of the whole blood, for such half brother claims through, and therefore takes *after* (rule 2) the mother, who (rule 4) is postponed to the father.

6. The mother of the more remote male ancestor inherits before the mother of the less remote; and the mother of any male ancestor before the mother. (See s. 8 of the new act.) Thus the father's mother takes before the mother, and the father's father's mother before the father's mother, &c.

These six rules, read one with another, will, it is believed, point in any case to the heir. It is observable, and in this respect the new differs from the old law, that there cannot be a nearer heir born after the heir who has inherited. Formerly the sister of the purchaser might inherit, and a brother of his be afterwards born, in which case the inheritance *shifted* to the latter. But at present this cannot be, as the father takes before his children (rule 2), and all children in the womb are considered by law as if born. The practical difficulty in finding an heir or proving a title by descent is, not to understand the law, but to ascertain and prove the facts on which the law must operate. (As to this, see Burton's *Compendium of the Law of Real Property*.) The new act provides against the difficulty of tracing descent from the purchaser, by the enactment that the last owner shall be always presumed to be the purchaser till the contrary is proved (s. 2).

To comment at length upon the rules regulating the course of descent is beyond our limits. Some observations and references are however necessary. Rule 3, which makes the eldest son, brother, &c. sole heir, exclusive of the other children, or the other nephews and nieces, &c., is well known by the name of 'the law of primogeniture.' It is almost peculiar to our country, not having been observed by the ancients, and being generally abolished where it existed on the Continent and in the United States of America. For the history of this rule, see Hale's *History of the Common Law*; Sullivan's *Lectures*; Robinson on *Gavelkind*; 2 Blackstone's *Com.*; Wright's *Tenures*; and for observations on its expediency, Smith's *Wealth of Nations*. The preference of males to females is not so peculiar. The Jews, Athenians, and Arabians, though not the Romans, gave the inheritance to sons exclusive of daughters. (For the Athenian law of inheritance, see Jones's *Isæus*; for that of the Jews, Selden *de Successionibus apud Hebræos*.) This is not however the case among most foreign nations at present. The preference of the child of the elder son dead in the purchaser's lifetime to the younger son (which we have endeavoured to show is the necessary consequence of rule 1) has some interesting historical associations. The law on this point seems to have been derived from the civil law, and not to have been settled till after most of the other rules of descent. It was still somewhat doubtful when King John kept his nephew Arthur from the throne by disputing it. (See 2 Bl. *Com.*; Sullivan's *Lectures*, lect. 14. In Robertson's *Charles V.*, vol. i., p. 272, there is a curious story of the trial by combat of this point of law.)

The descent of estates tail (regulated by stat. 3 Ed. I., c. 1.) differs from that of fees simple principally in this, that only the descendants of the first donee can inherit; and of these only males claiming exclusively through males can be heirs when the estate is in 'tail male:' when it is in tail female (a mode of gift which is quite obsolete), only females claiming exclusively through females. [ENTAIL.] The limited descent of the estates, together with other qualities of them, makes them the best representatives at present existing (excepting indeed copyholds) of the antient fiefs.

(On the law of descent, as it existed before the late act, see Sir Matthew Hale's *History of the Common Law*, chap. xi.; 2 Bl. *Com.*, chap. xiv.; Cruise's *Digest*, vol. iii. Watkins on *Descents* principally treats of curious points, many of which have ceased to be important. As to the reasons for the new alterations, see *First Report, Real Property Commissioners*.)

DESCENT OF BODIES. [FALL OF BODIES.]

DESERTER, an officer or soldier who, either in time of peace or war, abandons the regiment, battalion or corps to which he belongs, without having obtained leave, and with the intention not to return.

As the last-mentioned circumstance distinguishes the crime of desertion from the less grave offence of being absent without leave, it becomes necessary, before the conviction of the offender, that evidence should be apparent of such intention. This evidence may be obtained generally from the circumstances under which the deserter is apprehended; for example, he may have been found in a carriage or vessel proceeding to a place so distant as to preclude the possibility of a return to his corps in a reasonable time; or letters may have been found in which an intention to desert is expressed; or some offer may have been made by him of enlisting in another corps, or of entering into some other branch of the service.

The civil courts of law, in this country, have ever had authority to try offenders accused of desertion; but they have long since ceased to exercise such authority, and they now interfere only in the rare case of an appeal from the decision of the court-martial which is held for the purpose of investigating the charge and awarding the punishment. The latter courts are permitted the exercise, to a certain extent, of a discretionary power in proportioning the punishments to the degrees of criminality in the accused; and this power is generally considered as more likely to promote the ends of justice than the inflexibility of the law in civil courts, where, since no middle course can be taken between condemnation and acquittal, the criminal frequently escapes through the compassion of the jury, when the punishment which by law must follow a verdict of guilty appears disproportionate to the crime. The leniency which has invariably characterised the decrees of courts-martial, and the custom of not awarding the punishment in its full extent till after a repetition of the crime, sufficiently justifies the confidence reposed in those courts.

The practice of deserting from one regiment or corps, and of enlisting in another, either from caprice or for the sake of a bounty, having been very frequent, a particular clause has been inserted in the Articles of War, in order to prevent this abuse. It declares that any non-commissioned officer or soldier so acting shall be considered as a deserter, and punished accordingly; and that any officer who knowingly enlists such offender shall be cashiered. It is also declared, that if any soldier, having committed an offence against military discipline, shall desert to another corps, he may be tried in the latter corps, and punished for such offence; and his desertion may be stated before the court as an aggravation of his guilt. Any officer or soldier who may advise or encourage another to desert is also punishable by a general court-martial.

Absconding from a recruiting party within four days after having received the enlisting money is also considered as desertion. And an apprentice who enlists, representing himself as free, if he afterwards quits the corps, is esteemed a deserter unless he deliver himself up at the expiration of his apprenticeship. Vagrants also, who, pretending to be deserters, give themselves up as such with a view of obtaining money or provisions, are, by a clause of the Mutiny Act, to be considered as soldiers whether enlisted or not.

A non-commissioned officer or soldier who simply absents himself from his corps without leave is exonerated from the graver part of the charge, if any circumstances can be adduced from which it may be inferred that the absence was intended to be but for a short time. Such circumstances are,—goods of value being left behind,—the occupation in which the absentee is found to be engaged being in its nature temporary,—an intention of returning having been expressed,—or again, the offender suffering himself to be brought back without resistance. Simple absence without leave is referred to regimental courts-martial, merely, and these award the punishment discretionally.

The Mutiny Act authorises general courts-martial to condemn a culprit to death, should his crime be found to deserve the extreme punishment; in other cases they may sentence him to be transported as a felon, either for life or for a term of years, or to serve in the ranks for life, or for a length of time exceeding that for which he had originally engaged to serve. In some cases, also, corporal punishment is awarded, and an offender may be sentenced to lose the increased pay or the pension to which he would have been entitled if the guilt had not been incurred.

The crime of desertion is justly considered as one of the greatest that can be committed by any man who has

adopted the profession of arms. The officer or soldier who has undertaken to assist in the defence of his country, and steals away from the duties he is called upon to perform, violates a sacred engagement, and shows himself insensible to the dictates of honour, patriotism, and morality. Whether he withdraw through caprice, or to escape the privations to which the soldier is occasionally exposed, he sets an example of discipline infringed, he deprives the army of his services at a time perhaps when he can with difficulty be replaced; and while he basely seeks his own ease, he throws an additional burthen upon his companions in arms. If he pass over to the enemy, he becomes the vilest of traitors; and, should he escape the retribution which awaits him from his injured country, he must submit to live dishonoured, an exile from its bosom.

DESERTS. This word is of very vague signification; it is used generally to designate an uninhabited place, a solitude, and in this sense is equally applicable to the fertile plains watered by the Marañon and the sandy wastes of Libya. It is, however, more exclusively appropriated to sandy and stony plains.

Whatever may be the origin of sand, whether it be the detritus of sandstone rocks or other quartzose masses, or to whatever causes it be due, we consider it is of great importance to man by reason of the fertility which its admixture with clayey soils procures, and by the innumerable uses to which it is applied in the arts.

In considering, however, the vast seas of sand which cover such an amazing proportion of the earth's surface, we are tempted to believe that there is too much of it, and that it had been better if in its stead were rich meadows and arable land; but since deserts exist, we must remain persuaded that they are necessary to the general economy of the globe.

Deserts of sand are much more abundant in the old than in the new world. Almost every plain, even the best cultivated in Europe, contains patches of sand of greater or less extent; but to confine ourselves to *deserts*, properly so called, let us consider the immense surface which they occupy on the antient continent.

Africa, from its western coast, between the Senegal river on the south and Marocco on the north, to the border of the Red Sea, presents one vast sea of sand, occupying upon an average about 48 degrees of longitude and 10 of latitude, which is but partially interrupted by a projecting part of Fezzan and by the narrow valley of the Nile. This sterile region is divided into two unequal parts; the more considerable, that to the west, being called the Sahara, or Great Desert, and the other, to the eastward, sometimes bearing the name of the Libyan Desert. Both the one and the other inclose a few small fertile spots called *Oases*, which rise in the midst of the sands like islands in the ocean. They serve as resting-places to the merchants, who, by means of camels, poetically termed the ships of the desert, traverse these dismal regions.

The Desert of Sahara is represented to us as covered with moving sands formed into ridges like the waves of the sea. In the midst of these sands, whose position and aspect are continually changing by the effect of the wind, are dispersed a few rocky hills, and small hollows where the collected waters nourish a few shrubs, ferns, and grasses. The mountains which bound the desert on the west present insulated pinnacles, descending gradually into a plain covered with white and sharp siliceous stones, and which is at last confounded with the sands. At Tegazza, and some other places, a gem salt, whiter than the whitest marble, extends in vast beds beneath a stratum of rock.

'During the greater part of the year,' says Malte Brun, the dry and heated air presents the aspect of a red vapour; the horizon seems beaming with the fires of innumerable volcanoes. The rains, which fall from July till October, do not extend their uncertain and momentary benefits to all parts alike. An aromatic herb resembling thyme, the plant which bears the Sahara berry, acacias, and other thorny shrubs, nettles, and briars; such is the only vegetation which is met with on a few spots in the desert: rarely is a grove of date trees or of other palms to be seen. A few monkeys, a few antelopes, content themselves with what little food they can find. The ostrich also inhabits this region in numerous flocks, feeding upon lizards and snails and a few coarse herbs. Lions, panthers, and serpents, often of a monstrous size, add to the horror of these dreadful solitudes. The desert presents no traces of

a beaten path, and the caravans that traverse it, directing their way by the polar star, describe a tortuous road in order to profit by the oases, described as brilliant with vegetation, but which probably owe a great part of their reputation to the contrast they form with the absolute barrenness of the desert.'

Such is the dryness of the terrible burning wind named Samoom, Samum, or more properly *Samiel*, that it frequently absorbs the water contained in the skins borne by the camels for the use of the merchants and drivers. A last cruise of water has been sold for ten thousand drachmas of gold. In 1805, an akkabah or caravan, composed of 2000 persons and 1800 camels, not having found water in the usual halting places, they all, men and animals, perished of thirst. It is in the desert that is seen most particularly that singular optical illusion termed the *Mirage*.

Desert of the North-East and East of Africa.—The great sandy region, as we have said, is contracted in one place by the country of Fezzan. To the east and south of this are deserts occupied by the Tibboos, a nation of Berbers; whilst on the north-east the desert of Barca, the antient Cyrenaica, extends as far as the Mediterranean: both these are continued on the eastern side by the great desert of Libya, which borders on Egypt, forming its western boundary. These deserts differ little in character from the Sahara. To the south, the Libyan desert joins the equally sterile region of northern Nubia; leaving which, and crossing the Nile, we again meet with sandy and rocky tracts, which, from Abyssinia on the south as far as Suez on the north, occupy the whole space between the river and the Red Sea.

Deserts of Arabia.—Passing from Africa to Arabia, we first meet with the sandy hills which form the isthmus of Suez, and separate the Arabian gulf from the Mediterranean, whose coast-line they follow as far as Palestine. Immediately to the south of these sands extends the stony and barren tract known by the name of Arabia Petraea. Mount Sinai, an imposing mass of granite, is there surrounded by rocks of inferior height, composed in part of sandstone, and inclosing a few fertile valleys producing grapes, pears, and other excellent fruits; but the country in general is of frightful sterility, presenting nothing but a few shrubs of Egyptian thorn (*acacia vera*), which furnishes the gum arabic, with capers, and a few other plants, intermixed with rocks of a blackish granite, of jasper, and of sienite, and plains covered with sand, flints, and rolled stones. There are however large herds of gazelles and other game.

On the south, as far as Hadramaut, and bounded on the east by the Euphrates and Persian Gulf, and on the west by Hejaz and Yemen, extend the vast deserts of Nejd and Ahkaff, which produce nothing but a few saline plants, and their general appearance differs little from the deserts of Africa, unless it be that they contain many hilly oases adorned with palms and date trees.

Continuing our route towards the Euphrates, we leave on our left that part of the Arabian desert which bears particularly the name of the Desert of Syria, which extends northward as far as Haleb, and in the middle of which the traveller discovers the extensive and solitary ruins of Palmyra, the once magnificent residence of Zenobia.

Desert of Mesopotamia.—Having crossed the Euphrates, we find ourselves in the antient Mesopotamia, so called from two Greek words signifying *between the rivers*, i. e., the Euphrates and the Tigris, and which, in the most extended sense of the name, includes Aljezireh on the north, and Irak-Arabia or Babylonia on the south.

With the exception of narrow slips along the two rivers just mentioned, Mesopotamia is a desert still more horrible than those of Africa and Arabia, of which it may be regarded as the continuation. It is covered with burning sands and sterile gypsum. Wormwood and certain aromatic shrubs are the only vegetation, which, covering immense spaces, banish all other plants. The waters of this desert, mostly all saline or sulphurous, give rise to pestilential miasmata, which remain suspended over the desert till, the equilibrium of the air being disturbed, there is formed that pestiferous wind so justly dreaded in Syria and the neighbourhood, and which suffocates any one who has temerity enough to expose himself to its influence.

This desert, occupied by Arabs living upon plunder, is traversed by the caravans which carry on the commerce between Haleb and Bagdad. Its southern portion, or Irak-Arabia, presents, by reason of the proximity of the two

rivers, an aspect quite different from that of Aljezireh. That portion of the plain which forms the antient Babylonia is covered with alluvium, and, like the delta of Egypt, is periodically inundated. It is an immense meadow, requiring only the hand of industry to be covered as heretofore with abundant harvests, and to become once more the garden of Asia.

Deserts of Persia.—Scarcely have we left behind us these dismal regions, still directing our course eastward, and near the 34th parallel of N. lat., when we meet with the mountains of Kurdistan, covered with forests, and intersected by fruitful valleys.

Having scaled this wall, which forms the eastern boundary of the basin of the Tigris and Euphrates, we find ourselves on the high table-land of Persia, where we again meet with extensive deserts, some of them sandy, such as we have already seen, but more generally of an argillaceous soil; and thus it is that the Persian deserts seem to form the transition between those of Africa and Arabia and the Tartarian *steppes*.

In Persia there are five principal deserts, which occupy about three-tenths of the surface of the country. Of these the first is the great salt desert, which separates Irak-Ajemi from Khorassan, and is about 130 leagues long and 70 wide. On the south it joins the desert of Carmania; on the east it unites to the province of Khorassan. Its soil is a stiff clay, whose surface is covered with a saline efflorescence in some places an inch thick; and its vegetation, as in all the high plains of the country, consists of saline plants, such as the *Statice Tartarica*, intermingled with a few patches of pasture. The three other deserts are those of Kiab, of Meckran, and of Karakoum. The desert of Meckran is in Beloochistan. It is bounded on the south by the sea of Oman, and is separated from the desert of Sinde in Hindostan by the Brahovic mountains and the Indus. It does not belong to the table-land of Persia, but to the basin of the sea, of which it forms the northern boundary, or coast line followed by a part of the army of Alexander the Great on its return from India. Its productions differ from those of the Great Desert, and consist of the Indian palm, and the aromatic shrubs of Arabia Felix. The desert of Karakoum is to the north of Khorassan; it is sandy.

Deserts of Grand Tartary.—Descending the Paropamian mountains which bound Khorassan on the north, and form in that direction the escarpment of the great highland of Persia, of which the sandy province of Kohistan seems to form the ridge, we enter upon the deserts of Independent Tartary. This country is bounded on the south by the Paropamisus already named, and by the lofty chain of the Hindoo Koosh, of which it seems to be the continuation; on the east by the high mountains [BOLOR TAGH] which separate it from China; on the north by some ridges which, on the one hand descend from the great Altaic chain; and on the other from the extremity of the Ouralian mountains; and on the west by the Caspian. It may be regarded as the north-western declivity of the great central plateau of Asia. It occupies a surface of about 60,000 square leagues, of which the greater half is a desert; for, with the exception of the immediate foot of the mountains and the water-courses, the whole country is condemned to drought and sterility. The saline and sandy plains extend even round the northern part of the Caspian as far as the Don, and, to the east of the Oural, join the steppe of Isim, claimed by Russia.

The country of Khwarezme or Karissum on the south of Lake Aral is now reduced, by causes among which the invasion of the sands is perhaps the most powerful, to the little district of Khiva, which rises like an oasis in the desert, and which a man may ride round in three days.

The Greater Bucharia, or Bokhara, is also surrounded by sands to the north and west. The whole of Independent Tartary at the present time perhaps hardly contains a population of five millions,—a proof of the extreme sterility of the soil.

On the south-east of the province of Kohistan, of which we have spoken, is situated Segestan, and the country of the Afghans.

Desert of Afghanistan.—Afghanistan is an extensive country, containing the city of Candahar. It is a vast sandy basin, except in the immediate vicinity of the mountains by which it is bounded on the east and north, and along the banks of the rivers Lhorah and Helمند or Hindamend, which latter traverses it from east to west, and terminates in the Lake Zorah. The land rises on the north-

east towards the lofty mountains which sustain the great central plateau of Asia, and from which descend the Indus towards the south-west, and the Ganges to the south-east.

The vast extent of arid deserts which we have just described, scarcely interrupted by the Indus itself, reaches to the very banks of the Hesydrus, the most eastern of the rivers of the Penjab.

From Cape Bojador on the Atlantic to beyond the Indus, the sandy region extends in a curved line of 1400 geographical miles, and, setting aside the fertile oases, is estimated by Humboldt as covering a surface of 300,000 square leagues; and yet, however extensive this tract, which seems condemned to eternal sterility, we have still to consider the great central table-land of Asia, not less arid than what we have just seen.

Deserts of the Great Central Plateau of Asia.—The first country we meet with as we go eastward is Little Bucharia, bounded on the north by the mountain chain of Alak, which separates it from Songaria, and on the south by the Moos Tagh and Great Tibet. On the east it joins Mongolia.

Little Bucharia is tolerably fertile near the mountains, whence descend innumerable streams, which uniting in the river Yarkand, flow with it into the Lake Lop, having no issue. The whole of the centre and eastern portion of the country is a sandy and salt desert.

Leaving on the north Songaria, which also contains immense arid spots, and whence the river Irtysh takes its rise, still continuing our route towards the east, we find the steril plain extending towards Mongolia, where it opens out to form the vast desert of Shamo, which extends to the Great Wall of China through a length of 500 leagues, rarely interspersed with a few fertile spots.

From the outer slopes of those mountains which inclose and sustain the central plateau, the highest in the world, descend those mighty rivers which, on the one hand, fertilise the great empire of China, and pour the tribute of their waters into the Pacific, and on the other, traverse the widely-extended *steppes* of Siberia to disembogue into the frozen ocean.

As for the area of the sandy deserts of the Tartarian table-land, it may on a very moderate computation be estimated at 100,000 square leagues, which, together with the former 300,000 for the African, Arabian, and Persian deserts, and about 100,000 more for the widely-spread sandy and barren tracts in the south of Africa, and sandy patches of Europe, gives a grand total of half a million of square leagues of desert in the old world alone; that is, a surface equal to the whole of Europe, or forty-four times the extent of Great Britain, and this without including the boundless *steppes* of Siberia, nor the marshy plains of northern Asia bordering on the icy sea.

The deserts of America being of a different character, and known by other names, as PAMPAS, SAVANNAHS, &c., are described under their proper heads.

DESHOULIÈRES, ANTOINETTE DU LIGIER DE LA GARDE, a French poetess, born of distinguished parents in 1633. Great pains were taken with her education: she learned the Latin, Italian, and Spanish languages, and studied poetry under the poet Hesnant, who often assisted her in her juvenile compositions, and polished her verses when defective. Her life was rather a romantic one. In 1651 she married the Seigneur Deshoulières, a lieutenant-colonel in the service of the Prince of Condé. She visited the court of Brussels in company with her husband, where she rendered herself suspected by the government, which caused her to be arrested and imprisoned at Vilvorde, near Brussels. Here she passed her time in reading the Bible and the works of the Fathers, until, after eight months, she found means to escape, with the assistance of her husband. They were shortly afterwards introduced to Louis XIV., and Mad. Deshoulières was soon esteemed one of the literary ornaments of the age. Not only did she write a variety of poems herself, but she was an object of adoration to the contemporary poets, who honoured her with the title of the tenth muse. Racine and Pradon having each written a tragedy on the subject of Phædra, Mad. Deshoulières brought upon herself some discredit by taking the part of the latter against the former, in ridicule of whom she composed a satirical poem. Racine, however, soon had his revenge, for Mad. Deshoulières brought out a tragedy which met with nothing but ridicule, and afforded him an opportunity

of writing a parody. She wrote several other dramatic pieces, but totally without success. The death of her husband, to whom she was greatly attached, was the occasion of one of her most popular Idyls; indeed her fame rests on her Idyls alone, the rest of her works having fallen into oblivion. She died in 1694, leaving a daughter, who obtained some celebrity as a poetess, and whose works are often bound up with those of her mother.

La Harpe, after saying that the Idyls are the only works of Mad. Deshoulières worth noticing, limits his commendation to three of them. He places her below Segrais, an old French pastoral poet, and justly censures her for treating books, flowers, &c., as if they were living persons. Thus, for instance, she envies a streamlet for bearing fish without pain to itself, and asks it why it murmurs when it is so happy? However, her little poem of *Les Oiseaux*, cited in La Harpe's *Cours de la Littérature*, is written with great lightness and elegance, and fully deserves the commendations bestowed on it by that severe though impartial critic.

DESICCATION is the chemical operation of drying bodies, and is effected in different modes according to the nature of the substance.

One of the simplest cases is that of drying a precipitate which has subsided in the fluid from which it is thrown down: this may be effected after due washing by transferring it to a glass, porcelain, silver, or platinum capsule, the weight of which being previously determined, that of the substance dried is readily found on weighing. Sometimes substances are dried merely by exposing them to the air, in other cases at a temperature regulated according to the nature of the substances, as at 100° or 212°, in warm chambers, or a sand heat, or at a red or white heat.

The desiccation of precipitates upon paper filters is very commonly effected to a certain extent by absorption, or by placing the filter and its contents upon a piece of chalk or upon a brick; the operation being completed either by exposure to the air, or in any of the vessels and at any of the temperatures above named. In many instances desiccation is performed by means of the air-pump, which is useful in those cases where delicate organic bodies, which would be injured even by moderate degrees of heat, require drying. Mr. Leslie's process consists in placing the substance to be dried (or a fluid to be evaporated) under the receiver of an air-pump, over a basin containing sulphuric acid, or some other substance having great affinity for water. The receiver being exhausted, the operation is left to itself. On account of the absence of the air, the moisture is readily vaporized and is quickly absorbed by the sulphuric acid; and the vaporization and absorption continue till the substance is dry.

Desiccation may be carried on at common temperatures without the process of exhaustion above described; thus a basin containing quick-lime with a moist precipitate placed above it, and the whole covered with a jar or receiver, will soon render the precipitate dry. Any deliquescent salt may be substituted in some cases for sulphuric acid or quick-lime, such, for example, as potash, carbonate of potash, and chloride of calcium.

In chemical investigations it is frequently necessary to deprive gaseous bodies of their moisture. The nature of the drying substance employed must depend upon that of the gas to be desiccated: thus ammoniacal gas is absorbed by chloride of calcium, and immediately by sulphuric acid; but potash or carbonate of potash answers well for it: again, chloride of calcium would be decomposed if exposed to sulphurous acid gas and some others; potash would absorb them, and its carbonate would evolve carbonic acid, and also unite with them. In fact care must be taken that the desiccator exert no chemical action upon the substance to be dried.

DESIGN. In the fine arts the word design (from the Italian *disegnare*, to draw) is employed in two very different significations: in the first place it is used merely to signify the act of drawing, or representing in lines, the form of any object; in the next place it expresses that combination of invention and purpose which enables the artist to compose a picture or a group, without reference to the material in which it is executed. The accurate conception of form and beauty is displayed in the most masterly degree in the ancient Greek sculptures; and in the invention of appropriate attitudes and perfection of physical form the design of the best Greek sculptors cannot be surpassed.

But of all the existing specimens of art the paintings of the Italian masters display the most consummate excellence in design, especially the Florentine and Roman schools, and among them Raphael's in particular. The conception of the story, and the ruling passion of the moment; the selection of forms appropriate to the dumb actors of the story; the invention of appropriate attitudes, not merely for the single figures, but for whole groups, artfully disposed in such manner as to be adapted at once to the freedom of nature and the intention of the artist to assign to each its position according to its prominence in the story; and the perfect execution of the design, placing before our eyes in a palpable shape the inward thoughts of the painter, combine to render the design of Raphael's works the most perfect in existence. Michel Angelo's power is more apparent in the conception and execution of forms purely physical, and his design is therefore of a more limited and less elevated style. In proof of this, a single figure, a mere life-study for instance, from his unrivalled hand may be contemplated with emotions of admiration and wonder scarcely less than those which we feel when the whole of his greatest work is before us. Raphael designed not merely to overawe the spectator with physical vastness, but to elevate him above the visible world. Human suffering, superhuman inspiration, and divine benignity are subjects within the reach of his pencil. The tortured figure of the chastised Ananias, the terrible power inspired into Peter, the prophetic absorption of the prophet near him, pointing with his finger to the source of that power, bring into the design of that one picture (the Death) the most awful and sublime speculations; and, if it is second to the Transfiguration, it is no less a model of perfection in design.

The student in design may discover the means by which former artists attained their power, by copying and analysing their works, namely, the sculptures of Greece, and the works of the old masters. But he must avoid following the implied advice of Reynolds, to do no better than store his mind with their thoughts, and give them forth second-hand as his own. That the greatest poets and painters have borrowed is no apology for an education which recommends only borrowing: to appropriate with justice and effect the thought of another, the borrower must be at least as great as the original inventor. A figure from Raphael in a poor design is only a mockery and a foil to the poverty of the rest. The legitimate object of study, or that part of study which seeks to shorten the process of education, is to discover the mode which other artists have pursued in disciplining their minds, and eyes, and hands, in order to comprehend and express the nature which they had to portray. In this way the student learns, not to pilfer the works of others, but to turn to the best account his own ability and industry, to produce originals instead of mere copies. The study of the best poets, of histories, and the lives of individuals, of emotions casually displayed in the events of daily life, and in fact everything that helps to teach a knowledge of human nature, and the working of its internal feelings, combined with an accurate knowledge of those external forms which must enter into every composition, will conduce to the development of a power of original design. For technical points no work approaches in utility to the *Treatise on Painting* by Leonardo da Vinci.

DESIGN, ARCHITECTURAL. The scheme, idea, or, as it is more usually termed, the design, whether for an intended building or that of one already erected, is shown by means of a series of diagrams or drawings, which being exact geometrical representations, therefore too technical and formal to satisfy those who look at them as pictures, and likewise in some degree imperfect as separate representations, yet, taken one with another, convey a much more exact and complete notion of the whole, both internally and externally, than can be obtained by any other mode of delineation; because they not only exhibit the actual forms and dimensions as they really exist, and not merely as they appear to the eye according to the situation of the spectator; but reveal the whole anatomy of the fabric, together with many particulars that are concealed from view in the edifice. Such drawings consist of *plan*, *elevation*, and *section*, besides others of *details*, or *parts at large*; and their number will depend either upon the nature of the building, that is, on its being more or less complex, or as it is intended to show it more or less fully.

Although a certain prejudice exists against such draw-

ings, on the score of their being too technical and difficult, they become, when once explained, intelligible enough to any person of common capacity, however ignorant he may be of architecture. To begin with the *plan* (the *plant*, or *plot*, as it is sometimes termed by old writers), as the first in natural order, it being that which must be determined upon before the walls can be raised,—it may no less briefly than clearly be described as the map of the building; consequently, any one who understands geographical or topographical plans of that kind can be at no loss to comprehend the nature of an architectural one; the latter being a far more exact and less arbitrary and conventional representation than the other class. By means of the plan we distinguish most clearly the exact shape and extent of the building as regards the space on which it stands; the thickness of the walls, the internal arrangement, with the forms, number, and areas of the rooms and passages into which it is divided; and the situation and width of the doors, windows, fire-places, staircases, &c.; the solid and raised parts, such as walls, columns, piers, &c., being shaded, and the voids or apertures in the walls, such as doors and windows, being left white. For every story of a building there must be a separate plan, although it is not usual in books of designs to give more than those of the ground-floor and the principal one above it, from which the arrangement and size of the rooms above them may be tolerably well guessed at, unless there should happen to be some uncommon deviation in such respects from those below. Plans may further be distinguished as simple or detailed: the former are mere *floor-plans*, indicating no more than belongs to the floor and walls, while the latter describe, by means of dotted lines on the floor, the projection of cornices, the compartments of ceilings, or the groining and coffering of those which are vaulted or arched; likewise domes and skylights. Or else, instead of expressing what belongs to the ceiling plane, a plan of this kind is made to indicate the pavement of floors, the situation of statues, sideboards, bookcases, and other pieces of furniture, particularly of the beds in sleeping-rooms, the position of which is of material importance. Sometimes, too, plans are given showing the exterior of the roof of the building, with its chimney-stacks, gutters, skylights, dormer-windows, parapets, &c.

Another species of plan is that termed a *block-plan*, namely, a map displaying the general mass of the building, together with its locality, either in regard to other edifices or not, as the case may be; and such plans are an exceedingly useful accompaniment to others, because they serve to make us acquainted not only with the structure itself, but with its situation. From a ground-plan alone, for instance, of St. Paul's, all that could be learnt in respect to the last-mentioned circumstance is, that it is insulated, whereas a block-plan would show the precise form and extent of the surrounding area; how confined and irregular it is, and how far it would be necessary to set back the houses in some places in order to reduce the whole to uniformity. Plans of this kind are, in fact, *special* maps laid down upon a larger scale, and therefore more exact and detailed, although less comprehensive than ordinary ones.

An *elevation* (formerly termed an 'upright,' in Italian *alzata*, in German *aufriß*) may be described as a vertical plan, showing the front or one external face of the building as raised upon the plan; it therefore gives the precise forms and measurements of every part, delineated geometrically according to scale, and not as they appear according to distance or the accidents of perspective, whether depending on the level at which the eye is placed, or as the building happens to be viewed parallelly, or more or less obliquely. When the elevation is a single general plane, as is the case, for example, with the Travellers' Club House, in London, it will not differ very much from a direct front view, the projections being only those of the cornice, the dressings of the windows, &c., which are rendered manifest, and may be measured from their profiles; consequently, an eye unaccustomed to such drawings cannot be puzzled. It is necessary, on the contrary, that a person should understand the principle of geometrical drawing before he can form a correct idea of the subject, and judge what its actual appearance would be, if it consists of several planes or separate elevations placed one by the side of the other, all standing upon the same line, and without their returns or the planes perpendicular to and connecting them together, being shown;

because, unless the plan is also seen, the shadows alone serve to indicate what parts project and what recede beyond the general line of the front, and in what degree they do so, the shadows being at an angle of 45°, whereby they are made equal to the projection of the part which occasions them, beyond the plane or surface they are thrown upon. This may be easily exemplified by St. Paul's Cathedral: in a geometrical elevation of the western front, the shadowing informs us (without referring to the plan) that the columns in the centre are at some distance from the wall behind them, yet do not form a projecting portico (or porticoes, one above the other); for that would cast a shadow from itself on the building; but that the parts behind the columns recede inwards. Again, we should perceive the whole of the cupola just as if it were immediately over the front, and *between* the two western towers. The only thing to indicate the contrary is, that the shadows would be less forcible, and a tint would be thrown over it, by way of expressing distance; and although, independently of that, no architect would imagine it to be so placed, yet it would be impossible to determine the precise distance from the front, there being no shadow cast upon it by any other part of the building. Consequently, this would remain to be ascertained, either from the ground-plan or from a lateral elevation of the building, in which the cupola would be shown above the transept. One particular in which elevations differ materially from other drawings and from the appearance of the objects themselves, is, that no distinction is made between curved horizontal lines and straight ones; so that whether the part be a plane or curved surface, can be understood only from the shadowing, unless there happens to be something that assists in denoting curvature of plan. Thus, the mouldings of the base of a column are all straight lines; consequently, without shadow to express rotundity, we could not determine whether they belonged to a flat or round surface, unless the shaft be fluted, in which case the flutes will diminish in width, according to their distance from the centre, as may be seen by referring to the cuts in the article COLUMN, pp. 385 and 386. So likewise, in respect to a tower without either apertures or vertical lines regularly placed, we cannot judge whether it be circular or not; whereas, if there be either, they suffice to show that the surface is curved, although represented only in outline; because the apertures and the spaces between them would become narrower in proportion as they are more distant from the centre, and their *reveals*, or inner surfaces, would appear. Still, without shadow, we should not know whether the surface was convex or concave, except by referring to the plan, or by the nature of the subject, there being no difference between the two as regards outline alone. This will be obvious when it is understood that the elevations of curved surfaces are projected, as it is termed, from their plans, by lines drawn perpendicularly to the geometrical plane of representation, which determine where the vertical lines to be shown in the elevation will fall, and the distances between them; consequently, whether the elevation be projected from a convex or concave plan, the result will be the same. When no curved parts occur in the elevation, the process just described is superfluous, because the measurements may be taken at once from the plan. The same method, however, it should be observed, is employed for polygonal figures as for circular or curved ones. Thus, of an octagon three sides would be shown in elevation: yet, although of the same width, the two diagonal or oblique ones will appear narrower than that seen directly in front; and the same applies to all oblique surfaces, let the angle they are placed at be what it may; and to such likewise as are oblique to the horizon as well as to those which are vertical. Hence a roof terminated by gables or pediments at the ends of the elevation will, as regards outline, be drawn as an upright plane, and the sloping lines of the pediment will appear vertical.

Notwithstanding, however, these circumstances, which are apt to perplex those who are prejudiced against geometrical drawings because they are not satisfactory as 'pictures,' a person at all accustomed to them is so far from being in danger of misconceiving them, that it would require an effort on his part to imagine the objects other than what the drawings are intended to express—to fancy a semicircular projection to be a plane, or the profile of a pediment to be upright.

Nevertheless, although the whole may be perfectly well

understood, it is not always that sufficient allowance is made, even by architects themselves, for the great difference which sometimes occurs between an elevation and the building itself; or that the real effect is duly considered beforehand. Recourse is therefore occasionally had to what is termed a *perspective elevation*—a kind of conventional representation, partly geometrical, partly perspective, and combining in some degree the advantage of both modes, although strictly neither of them. As in elevations of the usual kind, the building is shown exactly parallel to the picture, with the point of sight precisely in the centre, at the proper height from the ground, and as far as regards the first or principal plane, is treated as any other geometrical drawing; but the parts beyond this plane are thrown into perspective so as to show the sides of projections, the soffit of entablatures, the ceiling and pavement within porticoes, and how much of a dome or other part of the structure, standing back from the front, would be concealed from view, at a given distance. It may be further observed, that elevations, both those of the above description and such as are strictly geometrical, have very frequently a pictorial character given them, not only by colouring as well as by shadowing, but also by the addition of sky and background. Yet it would be better were such accompaniment no more than what is just sufficient to relieve the building, instead of being extended over the whole drawing, and carefully worked up; because it is calculated to seduce the eye, while, by making too great pretensions to the character of a picture, it causes the elevation itself to appear offensively formal and unnatural. In fact, *outline elevations* (which mode is now generally adopted in modern architectural publications, especially foreign ones) are preferable to those which are shadowed, as they exhibit all the forms more distinctly, and admit of being measured with much greater exactness. They do not, indeed, convey any notion of effect; yet that may very well be dispensed with in such drawings, particularly if they be accompanied by perspective views.

We now come to speak of *sections*, which are for the interior what elevations are for the exterior of a building. A section or profile (in French *coupe*, Italian *spaccato*, German *durchschnitt*), is a plane cutting through the structure on some line of its plan, and showing the thickness of the walls and floors, the heights of the rooms, the forms and profiles of ceilings, whether plain or decorated, flat, coved, or arched; also the exact forms of domes and skylights. In fact it exhibits all the separate elevations of the rooms intersected by such plane, that is, the elevation of that side of them which faces or lies behind the plane of representation. In addition to the particulars just enumerated, we are by this means made acquainted with a variety of others, in regard to which a plan cannot be made to afford any information. The thickness of the walls may be ascertained by the plan as well as by a section; so also might the height of the rooms be expressed in the former by means of figures, as the other dimensions generally are; and the form and size of the windows may be learned from the elevations; still we should not know what are the heights of the doors, how they are panelled and decorated, nor what is the form of the chimney-pieces, &c.; nor be able to judge so well of the general proportions of the apartments. Besides which, sections may be made to show much more than what belongs to the architecture alone, for there are many instances in which furniture, pictures, and other decorations and fittings-up, are introduced; and unless this be done, a section is apt to have a naked appearance, except the architecture itself be particularly interesting and rich. For detailed and filled-up sections it is usual to employ outline, with the walls and floors shaded, the former as more solid being made much darker than the latter. When, on the other hand, the elevations of the rooms themselves are shadowed, the thickness of the intersected walls, &c. are left white, in order to prevent confusion and exhibit the profiles better. It should be observed, too, that in sections of this latter description, it is the practice to throw a shadow from the side walls and ceilings of the rooms, as if it were a model of the building really cut through; thus producing an effect both disagreeable and unnatural, and by no means assisting towards rendering the representation more intelligible. Indeed, indispensable and interesting as they are, sections are a far more conventional mode of drawing than elevations, be-

cause they represent a building as it never can be seen at all, except where the front of a house has been taken down for the purpose of rebuilding it, while the floors and partition-walls are left standing; in which case any one may obtain a good idea of the nature of a section, but of one seen in perspective. Besides general sections showing the whole of a building from top to bottom, there are frequently partial ones, showing only the rooms on one floor, or even a single room, when it is desired to show it on a larger scale than could conveniently be done any other way. Or instead of this, recourse is sometimes had to a plan of the room with each of its elevations or sides drawn around it, as if laid down flat on the ground, by which means the whole of the apartment is described; for the ceiling may be represented on the plan itself. Horizontal sections again are occasionally made use of, in order to show more accurately than can be done upon a plan, not only the ceiling and its ornaments, but the soffits of entablatures, of window recesses and door-cases, also the capitals of columns and their projection.

Although not in general use, there are likewise many other modes and combinations which deserve to be pointed out. One of them is that of elevation and section united; that is, one half the drawing shows half the elevation, which, as far as understanding it, fully answers the purpose of an entire one; while the other half shows half the section. Another is that of *sectional perspective view*, which, while it serves the purpose of a section in regard to showing the exact form, profiles, and measurements, on the first plane, intersecting the structure, gives also a picture of its interior just as it would appear in any other drawing of the kind; the only difference being, that in this case the drawing extends beyond the interior, while in other views it is bounded by and confined within it. It is hardly necessary to observe that such a mode is suited only for showing a single space, and not one divided into separate rooms. It is exceedingly well calculated for displaying the interior of a portico, as it admits of the situation of the columns in front being shown by the foreground being made a *perspective plan*.

Besides the usual plans, elevations, and sections, there must likewise be *details* or *parts at large*, answering in some respect to what are termed working drawings; since without these we can judge only of the general design, but not of its minutiae and finishing, whether belonging to decoration or construction:—and far more may be learned, and that too more satisfactorily, by studying a single good example thoroughly, than by looking at many which are only imperfectly described. It is therefore to be regretted that published designs, unless they happen to be those of actual buildings, are so exceedingly defective in this respect, generally showing no more than a couple of plans with one or two elevations, while, although so very essential, sections are entirely omitted. In order to illustrate a subject properly, not only should there be a plan of every floor and an elevation of every side, but sections, both longitudinal and transverse, and as many of each as the nature of the plan may require.

Having done thus much to show the whole anatomy of the structure, we may then provide perspective views both of the exterior and principal parts of the interior, in order to show the character and effect, which, without such drawings, can be judged of only piecemeal, and inadequately even by those who perfectly understand the others. Yet however satisfactory as a representation, a perspective view of an interior must still leave much to conjecture, as one of the sides or ends of it cannot possibly be shown, while of the others two will be more or less foreshortened, so that if there be deep receding parts in them, they can be but imperfectly seen,—perhaps may be quite misunderstood; or can be well understood only by the aid of plan and section. In many cases, therefore, an interior would require two or even more perspective drawings in order to show it completely. But with every part of the building thus fully made out and described in drawings, the whole may be understood as well, in some respects even better, than by a model of it; for besides that the latter can do very little towards showing the interior—certainly not its effect, there is this drawback attending it, that it conveys no idea of situation or locality, and that, instead of the eye being confined either as to due distance or height, it views it from points from which the building itself can never

be seen under any circumstances. Neither has it the accompaniment of sky, background, foreground: a model exhibits the mere building alone—as it is, certainly, yet not as it appears; for it is seldom any attempt is made to give the proper local colouring—at least to do more than merely hint at it. By means of perspective views, on the contrary, provided they be sufficiently numerous and judiciously chosen, and not deceptively embellished with effects of rare occurrence, we may obtain a most accurate idea both of the architecture and of all its local accompaniments and accessories, whether favourable or the contrary. Of *bird's-eye* views of buildings [BIRD'S-EYE] we have said nothing, both because they are now seldom made use of, and because we consider them not only most awkward, disagreeable, and unnatural representations in themselves, but as altogether superfluous, if a building is properly described by the other modes, or even by a block-plan and elevation alone.

DESMAHIS, JOSEPH-FRANÇOIS-EDOUARD DE CORSEMBLEU, was born in the year 1722, at Sully-sur-Loire. His father designed him for the law, but he devoted himself to poetry, and at the age of eighteen came to Paris, where he was well received by Voltaire, and admitted into high society. He distinguished himself by a number of little poems, which enjoyed a considerable reputation in their day, but which, as most of them are suited to particular persons and occasions, and moreover are filled with mythological allusions, have little interest at present. The Greek mythology was put to a peculiar use in the days of Louis XIV. and those of our own Queen Anne; poems were written altogether in the court taste, and yet perpetual references were made to pagan gods. Not the slightest attempt was made to write in the true spirit of the Greeks, as Shelley and other modern poets, who have chosen mythological subjects, have done of late. Hence a variety of little works, which acquired a great reputation during the reign of a certain fashion, have fallen into oblivion on that fashion having passed away. The poems of Desmahis are precisely of this class. He wrote some comedies, of which 'L'Impertinent' was very successful in its day, but attempts to revive it have proved ineffectual, and La Harpe has censured it pretty severely. Desmahis was greatly blamed for the articles 'Fat' and 'Femme' in the 'Encyclopédie.' Instead of writing something that contained information, he only made two satirical essays in the style of Rochefoucauld. He died in 1761.

DESMARAIS. [REGNIER.]

DESMOND, and EARLS OF DESMOND. [CLARE and CORK.]

DESPOTISM. [MONARCHY.]

DESSALINES, JACQUES, a negro from the Gold Coast of Africa, was imported into the French colony of St. Domingo as a slave. Having become free like all his fellow slaves by a decree of the Convention, 4th February, 1794, he soon figured among the foremost in the insurrection of the blacks against the white colonists. He attached himself to the negro chief, Toussaint l'Ouverture, who made him his first lieutenant. His intrepidity, his extreme activity and quickness of movements, distinguished him in the war against the French troops, and particularly against generals Rigaud and Leclerc in 1802. After Toussaint's capture by the French, Dessalines submitted for awhile, and accepted an amnesty, but he was soon after at the head of a new insurrection against general Rochambeau, Leclerc's successor, and contributed greatly to the victory of the blacks at the battle of St. Marc, which decided the evacuation of the island by the French in October, 1803. Dessalines encouraged a general massacre of the whites, without distinction of age or sex. In 1804 he had himself proclaimed emperor of Haiti, under the name of Jacques I., and established his court in imitation of that which Bonaparte had just formed in France. But his cruelty and arbitrary conduct towards his former comrades led to a conspiracy, at the head of which were the negro chief Christophe, and Pethion, a mulatto. They rose upon Dessalines at a review, in October, 1806, and killed him on the spot. Christophe succeeded him as emperor of Haiti, by the name of Henri I.

DESSAU, ANHALT, a Saxon duchy in the north-west of Germany, bounded, where its limits do not touch the other duchies of Anhalt, Bernburg and Cöthen, by the Prussian province of Saxony. It is composed of six detached portions of territory, situated on the banks of the

Elbe, Mulde, Fuhne, and Wipper; and they are subdivided into

	Market Towns.		Vill. Houses.		Popula- tion.	Chief Town.

The duchy has an area of about 357 square miles: it extends from 11° 30' to 12° 35' E. long.; its most southerly point is in 51° 39', and its most northerly in 52° 7' N. lat. With the exception of some high ground in the bailiwick of Sandersleben, it presents a uniform and beautiful plain, the surface rising slightly along the banks of the Elbe and Mulde. The character of the soil varies considerably; the districts adjoining the Fuhne and Wipper are highly cultivated, and fertile in grain, vegetables, &c. the vicinity of the Elbe and Mulde is noted for its rich meadows and pastures; but the soil of Zerbst is poor and hungry, and many parts of Dessau Proper are sandy heaths. In general it may be said that the districts on the left bank of the Elbe are extremely fertile, and on the right bank sandy and unproductive. A fifth part of the surface of Anhalt-Dessau is covered by woods and forests, which occupy about seventy-three square miles, mostly on the left bank of the Elbe, about Wörlitz, Oranienbaum, &c., and from the abundance of game still render the duchy as famed in Germany as in former times.

The chief river is the Elbe, which traverses Anhalt-Dessau from east to west, and divides it into two very unequal parts, of which the larger lies on the left bank: its banks are defended by strong dams, called 'the Elbewall,' for the purpose of checking the inundations which at times devastate the adjacent lands. The Elbe separates Zerbst from the Prussian dominions, and is traversed by a flying-bridge, about three miles north of Dessau. All the streams in the duchy are tributaries of this river, either directly or indirectly; those of any importance which flow directly into it are the Mulde, a navigable stream, well known for its salmon, which comes from the bailiwick of Alsleben, receives the Wipper, and meets the Elbe at Henscheinen above Dessau, and the Ruthe, which enters the duchy from Zerbst. The minor streams, indirectly tributary to the Elbe, are the Taube, Wipper, Fuhne (the only native river of Anhalt-Dessau), and the Ziethe or Zittau, which flows into the Fuhne: the three first uniting their waters with the Saale, a tributary of the Elbe. The duchy is full of 'stillings,' narrow tracts of successive ponds or pieces of water, which bear evident traces of having been parts of the former beds of rivers; they partially skirt the course both of the Mulde and Elbe. There are a number of lakes also, the largest of which is the Pötnitz, situated between the Mulde and Elbe, and close to their confluence; the high road from Dessau to Oranienbaum passes across it by means of a wooden bridge, resting on stone piers. Lake Schönitz is of considerable length, and connected with Lakes Rehsen, Röttingen, and Döbritz. But the most picturesque is Lake Wörlitz, which is also connected with Lake Röttingen. All these receive their waters from the Elbe, and are supposed by many to have once been portions of an old bed of that river.

The climate of Anhalt-Dessau is temperate and healthy, though the inhabitants suffer at times from fevers and other diseases occasioned by inundations.

The industry of the people, encouraged by the paternal care of the government, who introduced the English system of husbandry in the latter part of the last century, has brought almost every available tract under cultivation, and placed the duchy in a situation to produce more grain than its wants require: and the same remark applies to fruit and vegetables. It grows all the ordinary descriptions of corn, as well as hops, hemp and flax, pulse, succory, madder, tobacco, rape seed (from which about 220 tons of oil are annually obtained). Buckwheat is raised in Zerbst, and yields large crops in wet seasons.

There are no mines in Anhalt-Dessau, nor any quarries, except those of limestone in the bailiwick of Sandersleben; neither has any advantage yet been taken of the beds of salt near Gröbzig and Sandersleben. There are beds of coal near the last-mentioned place, where also gypsum is dug; and at Qualendorf a species of agate is found which, when polished, has the appearance of diamonds. The soil near Zerbst is impregnated with iron, and there are chalybeate springs in this quarter. Here and there potters' clay and porcelain earth are obtained.

Game is so important a product of the duchy that the seignorial revenues derived from boars alone have at times amounted to 6000 rix dollars (about 850*l.*) a year. In 1688 we are told that 215 of these animals, some of them weighing from $4\frac{1}{2}$ to $5\frac{1}{2}$ cwt. each, were taken in one day. During the twenty years' interval, 1810 to 1829, 19,859 red deer and boars, including 2359 of the latter, were caught or killed. The lakes and rivers afford a good supply of fish, among which the salmon of the Mulde is highly esteemed; of this fish the produce for the seven years, 1817—1823, was 3348. Shadfish and sturgeons of large size are caught, and the lamprey is at times plentiful in the Mulde.

The duchy of Anhalt-Dessau, 23 years before the duchy of Zerbst was united to it in 1770, contained 31,909 inhabitants: in 1787 it had increased to 36,093; at the time of the union, in 1793, it was estimated at 38,000, exclusive of upwards of 10,000 for Zerbst; in 1812 the united territory had a population of 53,608, including 13,608 for Zerbst, at least according to Crome's returns. If he be correct, the numbers must have fallen off in the six years succeeding, inasmuch as they did not amount to more than 52,947 at the time of the census in 1818. The subsequent returns in 1830 state the number of houses in the whole duchy to be 8293, and of inhabitants 57,629, of whom 1125 were Roman Catholics and 1614 Jews. The males amounted to 27,471, and the females to 30,158. In the towns there were 4310 houses and 31,492 inhabitants; and in the rural districts 3983 houses and 26,137 inhabitants. Lindner observes that the duchy is more densely peopled than the other two duchies of Anhalt, Bernburg and Cöthen.

The rearing of cattle is an object of much attention in all parts, particularly on the private domains of the duke, which are very extensive, contain between 4000 and 5000 inhabitants, are let in large farms, and raise large crops of clover. The duchy abounds in fine pasture land. The whole stock of horned beasts in 1830 was 14,826, and most of them are of improved breeds. Greater care is taken of the flocks than in almost any other part of Germany, and the whole of those on the ducal dominions have been improved by crossing them with Merinos. Of sheep of all kinds the numbers in 1830 were 85,831. Less attention has been bestowed on the breed of horses, the stock of which in 1830 amounted to 4743. Swine are very generally reared.

The inhabitants being chiefly engaged in agriculture and rearing cattle, comparatively little attention is paid to manufactures. Linen-yarn is spun by the female peasantry in winter, and linens, including damask-cloths, are woven by small manufacturers and under the peasants' roofs, for home consumption only. There are manufactures of woollen cloths in Raguhn and Jessnitz, and on a smaller scale in Dessau, Zerbst, and other towns, whence there is some exportation.

There are tobacco manufactories at Dessau and Zerbst, and in the latter town an earthenware manufactory and wax bleaching grounds, as well as a large manufactory of gold and silver articles. Anhalt-Dessau has oil and paper mills, tile-houses, limekilns, potash and tar works, and tanneries, and manufactures leather, turnery, &c. The manufacturing part of the population, however, did not, in 1830, exceed 2796 masters and 2060 assistants, of whom upwards of one half (2557) were settled in the bailiwicks of Dessau and Zerbst.

The trade of Anhalt-Dessau is chiefly internal. Its external transactions do not amount to more than about 150,000*l.* per annum, imports and exports both inclusive. The exports consist principally of grain, rapeseed-oil, butter, cheese, timber, game, dried fruits, wool and woollens, fish, pork, linen-yarn, tobacco, turnery, and gold and silver wares. The imports consist of drugs and colonial produce, cottons, silks, &c. Dessau and Zerbst are the chief seats of trade.

The duke is uncontrolled sovereign, except with regard to taxation, which is subject to revision by the states-general of the three Anhalt duchies; and the affairs of the coun-

try are administered under his immediate direction by a secret cabinet (*geheime-kabinet*), and the revenue-board (*rent-kammer*), the latter of which administers the ducal revenues and domains as well as all matters of police. The supreme tribunals of justice are at Oranienbaum, Qualendorf, and Zerbst, in which last town is a high court of appeal for the three Anhalt duchies and the principalities of Schwarzburg-Rudolstadt and Sondershausen. The revenues (including about 19,000*l.* arising from the duke's isolated domains in Eastern Prussia, Brandenburg, and other parts of the Prussian dominions, of which the whole area is about 189 square miles, and the population about 12,000), are estimated by some at about 65,000*l.*; but Crome is of opinion that they are much underrated at that amount. The public debt is said to be about 92,000*l.* The military, on a war-footing, consist of a battalion each of regulars and militia; and the duke's contingent for the army of the German Confederation is 529 rank and file.

The national religion is the Lutheran; the non-conformists consist of about 1600 Jews and 1100 Roman Catholics. The number of parishes is 53, divided into two general superintendencies at Dessau and Zerbst. There are gymnasia or high schools in Dessau and Zerbst: in the former a seminary for educating teachers, and a Jewish school; and the duchy is so well provided with elementary and other schools that the proportion of children receiving instruction exceeds one in every nine inhabitants. (Lindner's *Hist. and Descript. of Anhalt*; Crome's *Anhalt-Dessau*; Hassel's *Principalities and Freestates of Germany*; Von Stein, Hörschelmann, &c.)

DESSAU, the capital of the duchy of Anhalt-Dessau, is situated on the left bank of the Mulde, about two miles from its junction with the Elbe, in $51^{\circ} 48' N.$ lat., and $12^{\circ} 18' E.$ long., at an elevation of 116 feet above the level of the sea. The town is about half a league in circumference: three sides of it are enclosed by a wall, and the fourth, towards the east, is bounded by the Mulde, which is crossed by a handsome bridge. Dessau has six gates, and is divided into the Altstadt, Neustadt, and the Sand, and three suburbs: it contains seven public squares, and thirty streets, which, upon the whole, are well and regularly built. Dessau may in fact be ranked among the better class of German cities: the Cavalier Street, would be an ornament to any capital, and some of the public buildings are handsome, especially the palace of the dukes of Dessau, which is a noble edifice, and contains some beautiful specimens of the old masters, and collections of works of art, coins, and engravings, among which are many excellent architectural designs; the palace or ducal chapel contains a chef-d'œuvre of Lucas Cranach, 'the Last Supper,' in which he has introduced portraits of Luther, Melancthon, and other contemporary characters. Among the other buildings we may mention the palace of the duchess-dowager, the town-hall, four churches, of which two are of the Reformed Lutheran ritual, one Lutheran, and one Roman Catholic; one synagogue, two hospitals, a poor-house, orphan asylum, infirmary, the Amelia and Wilhelmina foundation for the indigent and infirm; a theatre and musical academy, the fine ducal riding-school, and the public cemetery, which is laid out with great taste, and embellished with an elegant entrance in the Roman style.

Dessau is well supplied with schools of public instruction. The Franz school, for the education of Jews, is known throughout Europe. The gymnasium, or high-school, too, is an admirable institution, both for its system of instruction and the attention bestowed on the pupils. It took its rise from the Philanthropin, which was founded by Duke Francis in 1774, and remodelled in 1785. It is divided into three departments: an upper or classical school, consisting of five classes, which in 1819 had 79 pupils, and in 1830, 116; a citizens (*bürger*) school of three classes, which in 1819 had 123 pupils, in 1830, 160; and the elementary-school, which is preparatory to the two others, has four classes, and had 217 pupils in 1830. A small library and collection of models is attached to the gymnasium, which is besides in connection with the seminary for school-masters. Another excellent institution is the Louisa school of industry for the spinning of flax and cotton, the profits arising from which are partly divided among the children, and partly deposited in a savings'-bank; there is likewise a society for apprenticing young men to trades. The total number of children receiving instruction in the various public schools in Dessau is estimated at 1750, of whom 1020 are boys.

The population of Dessau in 1818 amounted to 9136, of whom 807 were Jews; in 1830, including the suburbs, it contained 1005 houses and 10,611 inhabitants, of whom 763 were Jews; and in 1836 the population was estimated at 10,900. They have but few manufactures, principally of cloth, stockings, hats, tobacco, vitriol, silver-lace, and beer: the retail trade is almost exclusively in the hands of the Jews. It however carries on a considerable trade in grain, &c., and has a salmon fishery on the Mulde. Dessau has three annual fairs. It is the birth-place of the philosopher Moses Mendelsohn, who died in 1786. In the environs are the ducal villas of Louisium, Georgium, and Vogelheerd, with gardens laid out in the English taste; the Drehberg is the burying-place of the dukes of Anhalt Dessau, which is excavated in an artificial mount, planted with shrubs, and surmounted by a building with a lantern and cupola; and the Stieglitzberg on the Elbe, with the monument to the memory of the duke of Dessau, who fell at the battle of Torgau.

It seems probable that Dessau, like many of the neighbouring towns, was built by the Dutch in the latter half of the twelfth century, under Albrecht the Bear; and though it is not mentioned by any existing records until 1213, it is, with some probability, conjectured that the church of St. Mary is of earlier date, the hospital having been erected some time previous to 1228. The school, which is the oldest in Anhalt, was founded in 1313. [ANHALT.]

DESTOUCHES, PHILIPPE NERICAULT, was born at Tours, in 1680. He much displeased his relations by turning actor, when they had designed him for the law. He wandered from town to town as director of a company of comedians, among whom he was distinguished by his strict morality and his great regard for religion. His first dramatic piece, 'Le Curieux Impertinent,' (founded on the episode of the same name in Don Quixote) was acted in 1710, and received with enthusiastic applause. Three pieces which followed seem to have had more success than they merited. In 1717 Destouches accompanied Cardinal Dubois to England, where he married an English Catholic lady, with whom on his return to France he retired to an estate in the country, where he passed nearly all the remainder of his life. In 1723 he was chosen a member of the Academie. About this time commenced his great reputation as a dramatist, for though his former pieces had been successful, they rose little above mediocrity. His 'Philosophe Marié' raised him to a high rank among the comic writers of France, and the envious critiques which were written against it only showed how highly it was valued. 'Le Glorieux,' which followed, was by some critics considered even superior to 'Le Philosophe Marié,' and La Harpe seems to be of this opinion; however the latter is generally considered the most perfect. He continued to write for the stage till his sixtieth year, though the pieces he produced were not equal to the two already mentioned; one of the most favorite was 'La Fausse Agnès,' a farcical comedy resembling Murphy's 'Citizen.' From that time he devoted himself to theology, and wrote several essays against infidelity. He died in 1754.

The 'Philosophe Marié,' on which, as we have seen, the fame of Destouches chiefly rests, is a model in its way. Although the subject and style of the whole are generally serious, there are situations and scenes which can scarcely be excelled for humour. The moral tendency of the piece is such as must give pleasure to a well-constituted mind. There are no hacknied sentiments or mawkish expressions, but the best of feelings are portrayed, and exhibited in so attractive a form, that even the bad characters of the piece are overcome by them, and the spectator feels that their conversion is perfectly natural. The very weaknesses which the author has implanted in his virtuous characters show that he knew human nature to be more interesting than a picture of faultless abstractions.

DESVAUXIA'CEÆ, an obscure and little known natural order of plants, consisting of a few New Holland sedge-like herbs, of no known utility. They are nearly related to Restiaceæ and Cyperaceæ, and are principally characterized among other glumose endogens by having several carpels placed in the middle of each flower. The most recent character is the following, given by Endlicher, in his 'Genera Plantarum.'

Dwarf Australian herbs with the appearance of a pigmy Cyperus or Scirpus; the roots fibrous or fasciculated. Culms filiform, undivided, leafless. Leaves radical, be-

tween thread-shaped and bristly, sheathing at the base. Spikelets hermaphrodite, in two ranks, one-flowered, or terminal and solitary with one or many florets. Glume single, anterior, or two nearly opposite each other, coarse. Paleæ none, or delicate, single or double, parallel with the glumes. Stamen single, anterior. Filament filiform, simple. Anthers turned inwards, one-celled, attached by the back above the base. Ovary either single and sessile (we would exclude this character) or several attached to a common axis at different heights, imbricated downwards, one-celled. Ovule solitary, suspended from the apex of the ovary, orthotropous, with the foramen regarding the base of the ovary. Styles filiform, simple, united to each other at the base. Stigmas simple, or with a feathery beard. Utricles membranous, dehiscing lengthwise at the side. Seed orthotropous, pendulous; skin leathery and rather hard. Albumen fleshy and abundant. Embryo antitropous, lenticular, applied to the albumen at the extremity of the seed opposite the umbilicus; the radicular extremity papillose, and regarding the base of the fruit. (*Genera Plantarum*, p. 119.)

DETACHMENT, in military affairs, is a certain number of battalions of infantry and squadrons of cavalry which are selected from an army for the purpose of being employed on some particular duty.

The danger of being beaten in detail renders it, generally speaking, improper to have considerable divisions of an army far separated from the main body, but in warfare many circumstances occur which render such a measure adviseable; as, for example, the necessity of keeping possession of certain important positions while the rest of the army is otherwise employed; of masking a fortress, or keeping a body of troops in check, during the temporary advance of the army into the enemy's country; or of protecting the magazines and ensuring the safety of convoys with provisions or stores. In these cases however, great precautions should be taken that the detachment may not be cut off; it should therefore be protected by some fortified place, or its distance from the main body should not be so great as to prevent it from rejoining the latter before it can be attacked by a superior force: good roads should of course exist, or be formed, by which it may retire if compelled.

Detachments, when judiciously disposed on a field of battle, may contribute much to a victory by turning an enemy's flank while a powerful attack is being made in front; but the greatest foresight and a perfect knowledge of the ground are necessary in order that the operations of the main body and the detachment may take place at the proper times. The king of Prussia (Frederick II.) seems to have been averse from making detachments on the field of battle; and, in his Instructions to his Generals, he observes, that they generally arrive too late or too early at the appointed place, on which account they frustrate the object which was intended by them. He quotes as examples, the defeat of Charles XII., at Pultawa, in consequence of the detachment which he sent out on the preceding evening having lost its way; and the failure of Prince Eugene to surprise Cremona from some such cause. The objection however does not apply when the army is able to make detachments without weakening itself too much, and when the divisions are not separated by local obstacles which might prevent them from succouring each other if required. At the battle of Vittoria, in 1813, the troops under General Graham may be considered as forming a detachment from the principal part of the army commanded by Lord Wellington and Sir Rowland Hill; and, as the communications between the divisions were very difficult from the nature of the country, so that the commanders were obliged to act independently of each other, the circumstances must have been very unfavourable for a unity of action; yet the event justified the measures taken, and the victory there gained completed the deliverance of Spain.

When an officer is detached with a few troops to watch an enemy, he should endeavour to get well acquainted with the ground, in order that he may be enabled to change his position according to circumstances, and he should keep his division concealed as much as possible. He may act offensively if a favourable opportunity should present itself, but, in general, his object is to gain information and keep the enemy on the alert rather than to fight. Men of intelligence should be appointed to such commands, which are frequently attended with considerable difficulty and danger;

but, on that account, the officer has the greater chance of distinguishing himself.

Small detachments are sent out in presence of the army to perform outpost duty, to throw up field-redoubts, repair bridges, roads, &c., or to protect the flanks on a march.

DETERMINE, a word applied in mathematics to those problems which have one answer only, or at least a certain and finite number of answers. Thus the problem, 'given the base of a triangle, and the sum of the other two sides, to construct the triangle so that its vertex may be on a given straight line,' is determinate; for the number of ways of solving it cannot exceed two. But if we omit the condition that the vertex is to be upon a given straight line, and merely require that a triangle shall be constructed having a given base, and two other sides of a given amount of length, the problem becomes indeterminate, that is, has an infinite number of solutions. The peculiarities of this subject, namely determinate analysis, are not striking: it is to the word **INDETERMINATE** that we must look for the most characteristic points of distinction.

DETINUE is the form of action prescribed by the English law for the recovery of goods and chattels which have lawfully come into the possession of a defendant either by delivery or finding. It does not lie for real property, but for mere personal chattels, except only deeds and charters. [**CHATELS.**] In this action the plaintiff recovers either the thing detained, or if the thing cannot be had, the value of it, with damages for the detention. In order to enforce the redelivery, the court will frequently give very large damages, with liberty to reduce them to a small amount on payment of costs and return of the thing itself. This is the only remedy at law for the recovery of a personal chattel in specie, unless in those cases where they can be recovered by replevin. The action of detinue is similar to the *actio depositi* of the civil law, and is identically the same in its properties, process, circumstances, and forms as the action of debt, with this difference, that one is for the recovery of a chattel, the other of money. In order to ground an action of detinue, which is only for the detaining, these points are necessary: 1. That the defendant came lawfully into the possession of the goods. 2. That the plaintiff have a property. 3. That the goods themselves be of some value. 4. That they be ascertained in point of identity. As in this action the defendant might formerly wage his law [**DEBT**], it has of late given place to the action of trover [**TROVER**], but the wager of law having been abolished by 3 and 4 W. IV. c. 42, it is probable that the action of detinue will again come into use. (F. N. B.; Fitzherbert, *Natura Brevium*.)

DETMOLD. [**LIPPE.**]

DETONATION is a chemical term employed to express combination or decomposition which occurs with noise and frequently with combustion. It may take place between bodies in very different states, as between gaseous bodies, a gas and a solid, &c. One of the simplest and most powerful cases of detonation is that which happens when two volumes of hydrogen gas and one volume of oxygen gas are mixed, and fired either by the taper, electricity, the action of spongy platinum or sudden compression; in this case the detonation is loud, and the result of the chemical action is water formed by the union, in the proportions stated, of the gases above mentioned.

The sun's rays falling suddenly on a mixture of hydrogen and chlorine gases cause them to detonate and combine with the formation of hydrochloric acid. A detonating tube for the union of gases is termed a eudiometer. [**EUDIOMETER.**]

Detonation also occurs when phosphorus, with chlorate of potash or with nitrate of lead, &c., is struck. And there are certain combinations of metallic oxides which detonate or fulminate, by slight friction, by heat, electricity, or sulphuric acid; such are the ammoniuret of silver and gold, fulminate of silver and of mercury. The chloride of azote and the iodide of the same element are very powerful detonating bodies. In some cases, as has been mentioned, the result of detonation is combination, as when oxygen and hydrogen unite to form water, chlorine and hydrogen to form hydrochloric acid, &c. In other cases decomposition occurs and is the result of detonation. Thus ammoniuret of gold is separated into metallic gold, and the ammonia is decomposed; iodide of azote separates into its elements, the iodine appearing as a purple vapour, and the azote assuming the gaseous form.

DETRITUS and **DEBRIS**, two words now universally received into the language, the former of Latin, the latter of French origin. They are very frequently employed in works of geology and physical geography, when treating of the formation of alluvial deposits. By *debris*, in geological language, is meant generally the fragments of rocks, boulders, gravel, sand, trunks of trees, carcasses of animals, &c., detached from the summits and sides of mountains by the effect of the elements, or resulting from sudden convulsions at the surface of the earth. By *detritus* we understand the same debris finely comminuted or pulverized by attrition. Debris in general comprises detritus; but detritus excludes the idea of the larger debris.

Modern debris seldom extend beyond the foot of the mountains whence they are derived, the channels of torrents, and the higher parts of the beds of rivers; detritus alone, except in the case of such things as float, being carried down to the mouths of large streams. The boulders which lie strewn over such great extents of land, and which are found at great depths below the surface soil, together with fossil trees, bones of animals, &c., are the debris of a former age, no cause now in action being apparently capable of bringing them to such distances from their original sites.

DETROIT, a fortified town and capital of the Michigan territory or State (for we believe Michigan has, in the present session of congress, 1836-7, been admitted into the Union) in the United States of America, is situated in Wayne county, on the bank of the river Detroit, one mile from Lake Saint Clair. The town was founded by the French about the year 1670; it was taken in 1812 by the English under General Brock, and recovered in the following year by the Americans under General Harrison. The fort is a regularly constructed work, with parapets and bastions, and surrounded by palisades, a deep ditch, and glacis.

Detroit is a thriving place, and carries on an active trade with Ohio and New York. Several lines of railroad have been projected, which, when completed, must add importantly to the trading facilities of the town. One of these lines, to connect Detroit with the east side of Lake Michigan at the mouth of the river Saint Joseph, was begun in the spring of 1836; when completed it will be nearly 200 miles long, and will accomplish a direct line of communication between Lake Michigan and New York, through Lake Erie. There were, belonging to the town in 1834, 13 steam-boats and 69 other vessels of the aggregate burthen of 4913 tons. The population of Detroit in 1821 was 1422; it had increased to 2222 in 1831, since which time the number has been greatly augmented. There are two incorporated banks established in the town, with capitals amounting to 1,550,000 dollars. Detroit is 526 miles northwest from Washington.

DETTINGEN, a market-town in the circle of Aschaffenburg and province of the Lower Main, in Bavaria: it lies on the right bank of the Main, has 80 houses and about 600 inhabitants. It was the scene of the signal victory obtained, on the 26th June, 1743, by the allied forces of England and Austria over the French army under the Marshal Duke de Noailles. The allies were commanded by the earl of Stair, and animated by the presence of George II., king of England.

DEUCA'LION, a prominent personage in the mythical traditions from which Greek history sprung up. He is represented as the son of Prometheus and Clymene (Schol. Pind. *Olymp.* ix. 72), or of Prometheus and Pandora (Strabo, ix. p. 443, and others), and is sometimes called the father (Thucyd. i. 3), and sometimes the brother of Hellen (Schol. Apollon. iii. 1086), the reputed founder of the Greek nation. The seat of his authority was Thessaly, from which, according to general tradition, he was driven to Parnassus by a great deluge (Apollodorus, i. 7, 2), which, however, according to Aristotle (*Meteorol.* i. 14), occurred between Dodona and the Achelous. But whatever may have been the scene of Deucalion's deluge, the old traditions represent it merely as a local one; and it was not till the time of Ptolemy Philadelphus, when the Hebrew scriptures became known to the Greeks, that some features borrowed from the universal deluge of Noah were incorporated into the story of the Thessalian flood. (See Clinton's *Fasti*, vol. i., p. 43, note.) The legend which tells how he repopled the wasted district by throwing stones behind him on Mount Parnassus, in obedience to the injunctions of the oracle of Themis, is well known to the readers of Ovid. (*Metam.* i.

375, foll.) The date assigned to Deucalion by the Parian Marble is 1548 B.C., and by Eusebius 1541 B.C.; but the stories connected with his history are so manifestly fabulous, that doubts as to his actual existence are unavoidably entertained, and it seems reasonable to conclude that he was a mere personification. It must be confessed that there are no etymological grounds for thinking so, as appears to be the case more or less with the early kings of Attica (*Philolog. Mus.* ii., p. 345, foll.), for the name Deucalion seems to signify nothing more than 'the illustrious' (Hesych. sub v. δευκίης), and is a possible name for a real person; it was also borne by a son of Minos II. (Apollod. iii. i. 2.)

DEULE, CANAL DE, is chiefly in the department of Nord in France. It commences in the river Scarpe and runs north-west to the neighbourhood of La Bassée; a small canal from that place joins it. It then turns to the north-east, passes through Lille, and turning again to the north-west joins the Lys at Denslemont near Warneton. Its course is partly in the department of Pas de Calais. Its whole length is about 40 miles. The part from the Scarpe to Lille is called Haute (or Upper) Deule, and was finished in 1690: from Lille to the Lys it is called Basse (or Lower) Deule.

DEUTERO'NOMY, the fifth book of the Pentateuch, or five books of Moses. The Hebrew title אֵלֶּה חֻמֹּתַי, *aleh hadebarim*, 'These (are) the words,' consists as usual of the commencing phrase, a mode of appellation similar to that adopted in technically quoting a legal instrument. Among the Rabbins it is also called *sepher tuckhuth*, 'the book of reproofs,' or 'denunciations,' of which there are many, as in chs. iv. ix. xxviii. xxx. xxxii.; and *Mishneh torah*, the repetition of the law, a restatement being made in this book of the Mosaic laws contained in the preceding books of the Pentateuch. The Greek title δευτερονόμιον, *deuteronómion*, given in the Septuagint translation, is equivalent to *Mishneh torah*, being composed of two words signifying 'second' and 'law.' By the Jews this book is divided into ten paraschioth, or chapters. In the translations the number of chapters is thirty-four. The events directly related by the writer are comprised in a period of five lunar weeks, from the commencement of the eleventh month to the seventh day of the twelfth month of the fortieth year of the wandering of the Israelites in the wilderness, after their departure from Egypt. The book is generally considered to have been written A.M. 2553, or 1451 B.C., by Moses, in the last year of his life, when at the age of 120, and in the plains of Moab (i. 5; *Numbers* xxxiii. 50, xxxv. 1), near the ford of the Jordan, where the Israelites afterwards crossed over into Canaan: not 'over against the Red Sea' (i. 1), as in the authorized version, where the word סוּף, *Suph*, the name of a city or nation, is wrongly translated the Red Sea, but as Dr. Geddes reads, 'in the wilderness on the other side of the Jordan, in the plain, over against Suph,' only 'eleven days journey from Mount Horeb,' the Israelites on their way from thence to the Jordan having wandered about nearly forty years. The opinion which attributes the authorship of this book to Moses is attended with difficulties which have induced Eichhorn and other learned commentators to assign a much later date to it than the age of Moses. The concluding chapter, which gives an account of the death of Moses, and of his having been buried by God, is believed by most but not by all of the commentators to have been not written by Moses, for some consider this account as a prophetic one, related in the past tense, a practice not unusual among the Jewish prophets. This last chapter is supposed by others to have been jointly or rather successively supplied by Joshua, Samuel, and Esdras. Dr. Adam Clarke adopts the opinion that it is properly the first chapter of the following book of Joshua. (Clarke's *Bible*, Alexander's *Heb. and Eng. Pentateuch*.) This opinion seems probable, as the Pentateuch in some synagogue copies is written as one continuous whole. However the assertion in verse 10, that 'there arose not a prophet since in Israel like unto Moses,' indicates a longer subsequent period than that from the death of Moses to the death of Joshua; and it must be remarked that the book of Joshua contains an account of the death and burial of Joshua (xxiv. xxix. xxx). The first book of Samuel also gives an account of the death and burial of Samuel (xxv. 1). Calmet suggests that the parts of the book of Deuteronomy which are not attributable to Moses may have been written by Aaron; but unfortunately for this suggestion the book itself contains an account of the

death and burial of Aaron, as having occurred long before the earliest time at which it is supposed to have been written. (Deut. x. 6.) Some writers have assumed that the whole book was written considerably after the age of Moses, probably after the return from the captivity of Babylon, when the sacred canon was re-collected and arranged; and they maintain that the entire plan of the book indicates it to be the work, not of Moses, but of another writer, who relates the proceedings of Moses historically in the third person, and occasionally introduces him as speaking at length in the first person. This dramatic style of the ancient Jewish historians commences at the sixth verse of the first chapter whence Moses speaks in the first person to verse 41 of chap. iv. The remaining nine verses of this chapter, and the beginning of verse 1 of chap. v., are by the writer. Moses is thence represented as speaking until chap. xxvii; in the 1st, 9th, and 11th verses of which the writer speaks. Thence, to the end of chap. xxviii., the words of Moses are continued. In verses 1 and 2 of chap. xxix. the writer speaks, and again in chap. xxxi., verses 1, 7, 9, 10, 14, 16, 22, 23, 24, 25, and 30; in chap. xxxii., verses 44, 45, and 48; in chap. xxxiii., 1; and finally throughout the xxxivth and concluding chapter. In the translation of the Bible by Dr. Geddes, all the parts consisting of the words of Moses are distinguished by inverted commas from the words of the writer by whom they are introduced. Besides an historical repetition from the preceding books of the Pentateuch of the events which passed throughout the forty years from the departure from Egypt, the book contains a complete recapitulation of the moral, ceremonial, and judicial law, exhibited in the preceding books of Exodus, Leviticus, and Numbers, with alterations, and some additions; as, for instance, that of the law (xxi. 18) which requires the parents of a stubborn son to lead him forth to be stoned to death by his fellow citizens. In repeating the 4th article of the decalogue (v. 12, 15), a difference from Exodus (xx. 8, 11) in the reason assigned for the sanctification of the Sabbath has occasioned considerable controversy on the subject. It is said in Exodus, 'the Lord rested on the seventh day, *wherefore* he blessed and hallowed the Sabbath day.' In Deuteronomy it is said, 'the Lord brought the Israelites out of Egypt, *therefore* he commanded them to keep the Sabbath day.' The thirteen first verses of chap. xxviii. proclaim the blessings promised to the observers of the law, and the fifty-five following verses recite the curses on the disobedient. The twelve last verses of the xxviiith chap. contain the twelve curses which serve to compose the Communion of the English Liturgy. The passages in chap. xviii. 15, 18, 19, are considered as prophetic of the Messiah, on the authority of Acts iii. 22, 23; and vii. 37. Chap. xxxii. consists of the last song of Moses, the poetry of which, in the opinion of a very competent judge, Bishop Lowth, is singularly magnificent. Dr. Adam Clarke remarks, that 'very few parts of the Old Testament Scriptures can be read with greater profit by the genuine Christian than the book of Deuteronomy,' which is to be considered as correlative with St. Paul's Epistle to the Hebrews. Some important amendments are proposed by Dr. Kennicott, in his 'State of the Hebrew Text,' especially in chap. xxxiii. 1-5, the adoption of which Dr. Clarke recommends, on account of 'the impossibility of giving a rational meaning to the text as it now stands.' In Wilson's 'Archæological Dictionary,' article *Law*, a valuable tabulated exhibition is given of the whole Mosaic Law, in three classes, moral, ceremonial, and political, with the places of references to Exod., Levit., Numb., and Deut. Dr. Adam Clarke concludes his commentary on the book with six elaborate chronological tables, for which he deserves the thanks of every biblical student. The 'Biblioth. Brit.,' by Watt, contains a numerous list of sermons and commentaries on Deuteronomy. (Eichhorn's *Einleitung in das Alte Test.*, abtheil ii., p. 385-433; Poli *Synopsis Criticorum*, tom. i., p. 751-895; Calmet's *Dict.*; Horne's *Introduc.*, vol. iv., p. 24; *Horæ Mosaicæ*, by Rev. G. Faber; *Lectures on the Pentateuch*, by Dr. Graves; *Comment. on the Mosaic Laws*, by Michaelis, trans. by Dr. Smith.)

DEUTZIA, a genus of deciduous shrubs, inhabiting the North of India, China, and Japan, and nearly allied to *Philadelphus*, with whose species they agree in habit, but from which they differ in having their flowers generally smaller and more panicled, and in the filaments being toothed, and placed on the outside of a cup-shaped disk.

DEUXPONTs (Germ. *Zweibrücken*), formerly a duchy but now a bailiwick (*Land-commissariat*) in the south-western part of the Bavarian province of the Rhine, is bounded on the south by France, and on the west by the Prussian province of the Lower Rhine. It has an area of about 1181 square miles, and a population of about 140,000 souls: and contains three circles, five towns, five market-towns, and 208 villages. The general character of the country is mountainous, with many gentle eminences, whose declivities and lowest parts are rich in woods, corn-fields, pastures, and vineyards. The principal river is the Blies, into which flow the Erlbach, Hornbach, Schwolb, and other streams. Deuxpontos produces rye, barley, oats, and other grain; rapeseed, flax, and hemp are cultivated in large quantities, but the two last are not converted into manufactured articles. Much attention is paid to the rearing of horses and cattle, and particularly to the breeding of sheep. There is abundance of wood. The only minerals are iron, copper, and freestone. There are few manufactures.

DEUXPONTs, the capital of the bailiwick, in $49^{\circ} 24'$ N. lat. and $7^{\circ} 20'$ E. long., is a pretty town situated on the Erlbach, about fifty miles west of Spire. It is embosomed in gardens and luxuriant meadows, encircled by eminences and woods. The town, which consists of the Old and New Towns, is surrounded by a wall, has a pleasant suburb, and is regularly built: it contains about 850 houses, and 7200 inhabitants, 5300 of whom are Protestants and 180 Jews. Of the public edifices the principal are a handsome old palace, part of which is at present used as a Roman Catholic place of worship, two Protestant churches, a gymnasium and lyceum, an orphan asylum, an hospital, and a school of industry. The inhabitants are engaged in various branches of industry, especially in breeding Merino sheep; linens, leather, oil, plaster of Paris, tobacco, and steel ware, are manufactured. The printing-press still exists from which issued the editions of the Greek and Latin classics, by Croll, Emser, and Erter. Deuxpontos is the seat of the judicial tribunals for the bailiwick as well as of its local government. Close to the town is 'Schifflick,' a country seat built by Stanislaus Lesczinski king of Poland, which has been converted into an establishment for breeding horses.

Deuxpontos, or 'Two-bridges' (in its Latinized form, *Bipontium*) derives its name from the site of its old castle between two bridges. Its origin is unknown, nor is it mentioned in history until the year 1197, when it was the property of the counts bearing its name. On the extinction of the direct line, in 1394, the earldom fell into the possession of Ruprecht, the elector-palatine, who divided it among his three sons, in 1410, all of whom being dukes, the country itself was thenceforward denominated a duchy. During the Thirty Years' War it was overrun by the Imperialists under Gallas, who laid siege to the town and treated it with great barbarity. Deuxpontos suffered also severely during the campaigns of Lewis XIV., and the French held possession of it until the peace of Ryswick in 1697, by the terms of which they were obliged to evacuate the place. As the duke, in the meantime, had died childless, it fell to the next heir, Charles XII. of Sweden, and, upon his decease, to the count-palatine: this prince also dying without children, in 1723, the duchy reverted to the house of Birkenfeld, the ancestors of the family who now occupy the throne of Bavaria. In 1793 Deuxpontos was taken possession of by the French, but it was restored to Bavaria in 1816, when other adjacent territories were added to it, and the whole was annexed to its dominion by the name of the Province of the Rhine.

DEVELOPMENT. (Algebra, &c.) A name given to the process by which any mathematical expression is changed into another of equivalent value or meaning, and of more expanded form. It is not to be understood that development either facilitates the calculation or the explanation of an expression, necessarily; it may sometimes do the one, and sometimes the other, but as often it is the reverse. Nevertheless, the mathematical use of an expression is frequently facilitated by employing its development, and this in a great variety of ways.

The expression of common algebra will frequently furnish instances of this. Let us take the development of $(x+y)^3$, namely $x^3 + 3x^2y + 3xy^2 + y^3$. The original expression implies an addition and two multiplications, while the development involves six multiplications as difficult as those of the original, two of a more simple character, and three

additions. Nevertheless the BINOMIAL THEOREM, of which the preceding is a particular case, is the foundation of many important branches of algebra. But the usual form of development is into infinite series [SERIES], a subject of peculiar interest, and the various points of which, as may readily be seen from comparison of mathematical writings, are not perfectly well settled.

The mere word development suggests only one question, namely, what connexion exists between the expression itself and its development. Are they both actual representations of the same arithmetical value? Or do they merely represent algebraical forms which have the same properties? There are cases in which the first question must be answered in the affirmative, and others in which the second question must be so answered, while it is palpably the contrary with regard to the first. Without entering into the reasons of such difficulties, it must here suffice to remind the student who seeks for such matter as is immediately connected with the common use of the word, that he must be cautious what he admits upon any point connected with it, since it may frequently happen that he will find himself endeavouring to reconcile a very narrow meaning of the term with the forms of expression used by writers who take for granted a knowledge such as can only be acquired by considerable experience and reflection. So wide is the modern use of the term, that the following caution may frequently be useful. When an author speaks of the development of an expression, remember that he may have so extended a signification of the word, that the student should consider him as meaning merely 'algebraical substitute,' or an expression which may be used for the original without change of algebraical properties. He will hardly understand what we mean, nor is it for our present purpose necessary that he should do so: our intention will be answered, if, in referring to this work for the use of this particular term, he should be distinctly made to understand that in all probability his difficulty arises from an indistinct view of the meaning of equality, or of the sign $=$, as employed in algebra, such as we conceive a very eminent modern English writer to have had, when he proposed, in order to overcome the difficulties attending the interpretation of a series, to consider *one* and *one* as having a meaning distinct from *two*.

There are two points connected with developments which it may be worth while to point out, as illustrative of this (at first sight) apparent want of connexion between an expression and its development, which it should seem ought to exist between two forms which are used indifferently each for the other.

1. An expression may preserve an algebraical identity with its development in cases where arithmetical identity is entirely lost. Let us consider the series $P = 1 + x + x^2 + \dots$ continued without end, of which it is an evident property that $P = 1 + xP$. And the same is also a property of its well known equivalent form $1 \div (1 - x)$ which is in truth nothing more than the value of P derived from the last equation. But suppose that $x = 2$, and there is no imaginable arithmetical connexion between $1 + 2 + 4 + 8 + \dots$ continued for ever, and $1 \div (1 - 2)$ or -1 . On this point see, INFINITE, DIVERGENT, and SERIES.

2. A development may present an intelligible result, in cases where the original expression altogether loses meaning. Thus, let the following expression be considered, 'the product of all whole numbers, beginning with 1 and ending with x ,' of which $1.2.3.4.5$ or 120 is a particular case. Considering this as a function of x , it is obvious that we can find meaning and value in all cases in which x is a whole number. But when x is a fraction, we lose all idea of meaning: what is implied for instance, by the product of all whole numbers up to $10\frac{1}{2}$? Nevertheless, when we take the approximate expression for this product mentioned in COMBINATIONS, or the series of which it is the first term, namely,

$$\sqrt{2\pi x} \left(\frac{x}{e}\right)^x \left(1 + \frac{1}{12x} + \frac{1}{288x^2} + \dots\right)$$

the difficulty has disappeared: this series is as easily intelligible and calculable when x is a fraction as when x is a whole number. This paradox, namely, an alteration of form giving more meaning to an expression than it had at first, is of a character which cannot be briefly treated.

The inverse word to development should be *invelopment*, so that while we say that $1 + x + x^2 + \dots$ is the develop-

ment of $1 \div (1 - x)$, we should also say that the latter is the *invelopment* of the former. But the latter term is never used, which frequently gives rise to a circumlocutory and sometimes defective mode of description.

DEVENTER, a fortified town in the province of Overysel, is situated on the right bank of the river Yssel, about forty-six English miles east from Amsterdam. Deventer was formerly a free imperial city, and a member of the Hanseatic league. The town is surrounded by a wall flanked with numerous towers, and defended by a broad deep ditch. The cathedral is a fine Gothic building, with an excellent set of bells. The college contains a well-chosen and extensive library; population 10,500.

DEVEREUX. [Essex.]

DEVICE, an emblem or ensign, formerly borne on shields or embroidered upon banners as a cognizance, contemporary, in the history of heraldry, with coat-armour itself. As early as the twelfth century, King Henry II. caused certain devices to be painted, which had a descriptive reference to his name: the *planta-genista*, or broom-sprig, and a jenet passing between two broom plants, the former of which is engraved upon the Great Seal of his son, Richard I., on either side of the throne. For many succeeding centuries these devices appear to have been confined to the royal use; but from the reign of Richard II., various houses of the nobility adopted their use. Thomas Mowbray, duke of Norfolk, appeared against Henry, duke of Hereford, in the celebrated just at Coventry, upon a horse whose velvet trappings were embroidered with lions and mulberry trees, intended to typify his name. The devices of greatest notoriety were the white and red roses, by which the contending families of the royal stem are still metaphorically described. From the close of the fifteenth to the middle of the sixteenth century the frieses, entablatures, and stained windows of the more sumptuous habitations were crowded with devices. The Bouchier and Stafford knots were of this description. Camden, in his *Remains*, has a section entitled 'Rebus, or Name-Devices;' these were probably adopted in imitation of the emblems which, during the Neapolitan wars of the fifteenth century, were painted by the Italian chiefs upon their shields, accompanied by mottoes or quotations descriptive of enterprise, or of the general character of the bearer. Such were called *Impresses*, from the Italian word '*Impresa*.'

DEVIL is the English name of the malignant evil being—the great spiritual adversary of mankind. He is regarded as the chief of a host of rebellious angels who, before the creation of the world, and after a contest with the obedient angels, headed by the archangel Michael, were expelled from heaven (2 Peter ii. 4; Rev. xii. 7–9; Jude 6.) for the sin of arrogance and insubordination. The etymology of the word is variously given by different lexicographers. Dr. Johnson, supposing its derivation to be from *διάβολος* (*diabolus*), considers *divel* the more correct mode of spelling. Others assert *devil* to be a mere contraction of *the evil*, as *God* from *the good*. (Lemon's *English Etymology*.) It is however apparent that, as Christianity was originally diffused throughout Europe from the church of Rome, the Latin *diabolus* and Greek *διάβολος* produced the Welsh *diafol*, Saxon *diöful* and *deofl*, Gothic *dioft*, English *devil*, German *teufel*, Dutch *duyvel*, French *diable*, Spanish *diablo*, and Italian *diavolo*, as these appellatives are similar not only in form and sound, but in designating the peculiar character of this evil being; and their existence is subsequent to the introduction of Christianity. The simple original signification of *διάβολος* (*διαβάλλειν*) is adversary, accuser, calumniator, opponent; it therefore serves to translate the Hebrew *יָצָן*

satan, which has precisely the same meaning. (Heb. and Gk. Lexicons of Parkhurst and Pasor.) The name *διάβολος* is applied to the spirit of evil as being specially the accusing enemy of the human race, who accuses them before God night and day (*ὁ κατηγορῶν*, &c. *Revelation* xii. 10). Divines enumerate about thirty different titles appropriated to the devil. The following are some of the principal:—

The god of this world (age, *seculum*), *ὁ θεὸς τοῦ αἰῶνος τούτου*, 2 Corinth. iv. 4. The prince of this world, *ὁ ἄρχων τοῦ κόσμου τούτου*, John xii. 31. The prince or power of darkness, the prince of the power of the air, *ὁ ἄρχων τῆς ἐξουσίας τοῦ αἵρος*, Ephes. ii. 2. The angel of the bottomless pit, *Abaddon* or *Apollyon*, *ὁ ἄγγελος τῆς ἀβύσσου*, *Ἀβαδδὼν*, *Ἀπολλύων*,

Rev. ix. 11. The prince of devils, *ἄρχων τῶν δαιμονίων*. The great red dragon, old serpent, devil and satan, *δράκων μέγας, πύρρος ὁ διάβολος, ὁ Σατανᾶς*, *Rev.* xii. 3, 9; and xxii. 2. A murderer from the beginning, a liar, and the father of lying, *ἀνθρωποκτόνος ἀπ' ἀρχῆς, ψεύστης, καὶ ὁ πατὴρ αὐτοῦ*. The tempter, *ὁ πειράζων*, *Matth.* iv. 3.

For explanations of numerous other appellatives, as Beelzebub, Lucifer, Belial, &c., we refer to the various works mentioned in the present article. The statements under the word Devil in Cruden's *Concordance* may serve to represent the doctrine of the church concerning the power and dominion of this being. Man, it is said, since the fall, is under the tyranny and slavery of Satan, who is an adversary surprisingly subtle, with strength greatly superior to ours; with malice the most deadly, and with activity equal to his malice. He has principalities and powers under his command, and walks about like a roaring lion (1 Peter v. 8) to tempt and betray us, seeking to involve us in sin, and to bring us to ruin and everlasting misery. In a work entitled '*The Attributes of Satan*,' 8vo., 1818; also '*An Essay on the Existence of the Devil, and his Influence on the Human Mind*,' 12mo., 1810, and an Essay '*On the Influence, Power, and evil Agency of Satan*,' 8vo., 1822, it is maintained that the same testimony which establishes the existence of God establishes also the existence of the devil, that is, an evil spirit, the enemy of the whole human race, who possesses the power of exciting evil thoughts and actions; and that though God in his wisdom has left his expulsion from heaven in mystery, there is no one point on which the Scriptures are more clear and explicit than this, that the hearts of men are under his dominion. In a subsequent part of this article we shall notice the discrepancy of opinion among Christians as to the reality and personal existence of this evil being.

It is not altogether useless nor un instructive to trace the history of opinions, however absurd they may be. As to the notions entertained of this evil being, it would be easy to show that in forming their speculations upon his nature, men early abandoned the plain words of Scripture, and by consequence fell into the wildest extravagances and conjectures. The more the knowledge of the original text and the exact study of it declined, the more did superstitious and unfounded notions as to this being obtain credit among mankind. The history of these absurdities is often ludicrous enough, but unfortunately the belief in supernatural agency of all kinds forms also one of the darkest chapters in the history of our race. Ignorance, which is the parent of superstition, is also the parent of cruelty and persecution. But as the popular belief in witchcraft is now gradually disappearing before sound knowledge, so the absurd and unscriptural notions of the nature and power of that evil being whom we call the devil have gradually lost ground since the Bible has been translated into modern languages and become the possession of the humblest reader. Divines too have at last discovered that a critical investigation of the original text of scripture, on this as well as other subjects of revelation, can alone lead to any true results.

An early sect of Christians we are told worshipped the devil. 'The Ophites,' says Tertullian, 'worship the serpent-devil more than Christ, because by him we have the knowledge of good and evil.' Of the conviction entertained by some of the early Christians of the supernatural power of the devil, we have abundant proof in the accounts of demoniacal possessions and exorcism recorded in the writings of the fathers. Saints Anthony, Bernard, and Dominic, we are told, had frequent communications with Satan himself. (Butler's *Lives of the Saints*.) Even Luther relates his personal discussions with the devil, whom he compliments as being a very expert logician, with a loud and sonorous voice, '*Diabolus sua argumenta fortiter figere et urgere novit voce gravi et forti*.' (Luther, *de Missa Privata*, tom. vi. p. 28.)

The curious work entitled '*Compendio dell' Arte Essorcista*,' by Girolamo Menghi, 12mo. 1601, gives a history of the supposed process of ejecting devils. The subject of the devil's battle with Michael and his expulsion from heaven excited during a long period the subtle wits of the schoolmen, in ascertaining when and where it was fought, what time it occupied, what was the number of forces arranged on each side, and what was the rank of each commander; questions which at length were determined by dint of logic, proving the battle to have lasted precisely three seconds, &c. (Reginald Scott's *Trea-*

tise on the Nature and Substance of Devils, fol. 1665, Lucifer's Fall, ch. 8. Heywood's 'Hierarchy of Angels, and Fall of Lucifer,' fol. 1635.) St. Jerome declares it to have been the common opinion of the primitive church that the middle region of the air between heaven and earth was still crowded with devils. During the sixteenth century the prevalence of the belief in the devil's supernatural agency was truly alarming. A sermon on witchcraft preached by bishop Jewel before queen Elizabeth, entreats her majesty to check the tremendous operations of the devil by exterminating his agents, the witches and wizards, who were then very numerous. ('Discovery of Witchcraft, by Reginald Scott,' fol. 1665. 'Doctrine of Devils the grand Apostacy, an essay to rectifie the undue apprehensions we have about evil spirits,' 12mo. 1676.) The following description of the devil's personal appearance in the days of Reginald Scott, is taken from the author's treatise on the subject. 'Our mothers' mayds,' he says, 'terrifie us with the ouglie devel, with hornes on his head, fier in his mouth, a huge tayle in his breech, eies like basons, fangs like a boar, claws like a tiger, a skin like a bear, and a voice roaring like a lion.'

Before the end of the last century, this extravagant superstition had greatly subsided, and tracts tending to make the existence of devils a questionable point began to appear even from ministers of the church; for instance, 'An Inquiry into the scriptural meaning of the word Satan,' by the Rev. Mr. Barker of Leeds, 8vo. 1772; 'Advocates for Devils refuted' by the Rev. H. Huntington, 8vo. 1794; 'An attempt to show that the opinion concerning the Devil or Satan as a fallen angel, and that he tempts men to sin, has no foundation in scripture,' by William Ashdowne, 8vo. 1791. The following work is of an earlier date, with a similar design, 'A critical Dissertation concerning the words Δαίμων and Δαιμόνιον,' 8vo. 1738. In these treatises it is contended that the word Satan is never used in the Old Testament as a proper name, to signify a fallen angel, or an evil spirit really existing: and that even Diabolus in the New Testament will admit of explanations which are inconsistent with the existence of the devil. A more recent and elaborate work, by a minister of the Unitarian community, the Rev. Russel Scott, is 'An analytical investigation of the Scriptural claims of the Devil,' 8vo. 1822. The proposition sought to be proved in this work may be stated in the words of the Rev. John Simpson ('Essays on the Language of Scripture,' vol. i. p. 159.) that, the word Satan or devil signifies, throughout the Scriptures, an adversary; that no single text, nor any number of texts in which these words occur, afford any proof of the proper personality or real existence of any such being as Satan or the devil is generally supposed to be; and that many distinct passages, and the general spirit of them all, oblige us to understand these terms figuratively, not of a *real*, but of an *allegorical* person.' Several hundred passages are adduced in proof and illustration of this statement, and it must be observed that the instances in which Satan and Diabolus, being taken in a particular instead of a general sense, have been unwarrantably Englished by the word *devil*, are sufficient to show the impossibility of forming any just argument on this subject from the authorised version, without referring to the words of the original text. The word Satan occurs in the Old Testament thirty-four times, and is variously translated in adaptation to preconceived dogmas, and occasionally in disregard of consistency, as in 1 Chron. xxi. 1, where it is said that *Satan* urged David, which is at variance with the statement in 2 Sam. xxiv. 1, which says the Lord in anger urged him, that is *an adversary*. God's angel stood as *Satan* (an opponent) before Balaam's ass to *satanize* (oppose) his progress. (Numb. xxii. 22. 32.) Dr. Campbell, in his 6th preliminary Dissertation (on διάβολος) observes, that the prefixing of the article restricts the signification to the devil, but that without the article the sense is accuser in general; otherwise in Titus ii. 3, the aged women would be exhorted to refrain from being, not false accusers, but *devils* (διάβολοι). We must here notice the work of Dr. Bekker of Amsterdam, 'Die Bezauberte Welt, oder eine gründliche untersuchung des allgemeinen aberglaubens betreffend die Art und das Vermögen Gewalt und Wirkung des Satans, und der bösen geister über den menschen,' Balthasar Bekker, S. T. D. 4to., Amsterd. 1673. Bayle, in one of his letters (tom. i. p. 340), says that the publication of this work caused a great commotion in Holland, and that the synods took alarm at the fact of a learned theologian having composed a book to demonstrate the

non-existence of the devil and his angels. The author adduces and explains all the passages in the Scriptures which relate to the subject, and concludes that there is no satisfactory evidence of the devil's existence: observing that, if all which is commonly believed about him were true, he would be infinitely superior to God in the extent of his power, in the number of his subjects, and in the ready obedience they render. The two following works are replies, 'De gebannen Duyvel weder in geroepen,' &c. (The banished Devil recalled) 4to., Amst. Dr. Bekker, 'Consideration over zyn Boek,' door I. S., 4to., Amst. Bekker's work is translated into French, 4 tomes, 12mo., 1694, Amst. Another very learned production nearly to the same purpose, is by the distinguished biblical critic John Salomon Semler, entitled, 'Versuch einer biblischen Daemonologie, oder untersuchung der lehre vom Teufel und seiner macht,' 8vo., Halle, 1785.

This and a large number of other treatises on the same subject are examined and replied to, in the 'Historia Diaboli,' by John Godof. Mayer, 8vo. 1780, a work written in Latin, and replete with curious learning and researches on the existence and power of evil spirits, and their state before and since their fall from heaven. The reader may consult also Schulz, 'Untersuchung über die bedeutung des worts Teufel und Satan in der Bibel.' Other learned works of Germany on this subject are G. F. Meyer, in 'philosophischen gedanken von den wirkungen des Teufels,' Cotta, 'historia dogmatis de angelis,' Edelman's 'Glaubensbekenntniss,' Faber's 'dissertat. de influxu adæmonismi,' Pfaffius 'dissertat. de operationibus diabolicis in hoc mundo.' Among the German adæmonists, or those who deny the personality of the devil, may also be named Wetstein, Webber, Naudæus, Wagstaaff, Reich and Damm. Unitarians, in accordance with the scriptural adæmonists of Germany, maintain that the Bible affords no sufficient evidence of the existence of a being purely malevolent, endowed with indefinite powers to do mischief, who shares with God the attributes of omniscience and omnipresence, and destroys his claim to omnipotence and infinite goodness. In rejecting therefore the theory of dualism, they attribute to God alone whatever exists, and especially refer to the passage in Isaiah (xlv. 7) where God expressly says, 'I create evil.' The reader may see the question as to those who in the Gospels are described as being possessed with devils treated at large by the commentators, and especially by Worthington, Barker, Lardner, and others.

The statements of biblical critics upon the subject of the temptation recorded in the first book of Genesis are very various and discordant. (See Edwards, Πολυποικίλος Σοφία, p. 61.) 'From the authority of many of the antient interpreters,' says Dr. Middleton, 'and from my own reflections, I have ever been inclined to consider the story of the fall of man as a moral fable, or allegory, in which certain doctrines are represented by a fiction of persons and facts, which had no real existence, for to understand it literally shocks at once the principle of probability.' (Middleton's Works, vol. ii. p. 131.) Dr. Clarke in his edition of the Bible declares this to be 'one of the most difficult and most important narrations in the whole book of God,' believing it however, in opposition to Middleton, to be, not an allegory, but a relation of facts. Dr. Clarke, finding the Hebrew word *nachash*, which is translated serpent, to be an ideographic term admitting of numerous meanings, resorts to the not very dissimilar Arabic word *chanas*, signifying ape, fiend, or satyr, and thence concludes that on this occasion the tempter assumed the form of a monkey, or ourang-outang, adding that the ability to chatter is all they have left of their original gift of speech which they lost at the fall. Such speculations, though supported by learning and ingenuity, can scarcely be said to be confined within the legitimate limits of scriptural interpretation.

Plutarch in his treatise on Isis and Osiris, speaks of the great antiquity and universality of the dogma of the two principles. All nations, he says, have admitted two deities, one the author of good, the other of evil. In Persia, the deities of good and evil, or light and darkness, were Oromasdes and Ahrimanes (ARIMANES); in Egypt and Phœnicia (Sanchoniathon), Osiris and Typhon.

As to the account of the origin of evil in the antient cosmogonies the student will find a store of erudition rather curious than useful in 'L'Origine de tous les Cultes,' par Dupuis, 4to., tome ii., c. 5; tome iii., c. 1. In Beausobre's 'Histoire de Manicheisme,' 4to., tome ii., l. 5; Bayle's Dict.,

art. 'Manicheens'; Dr. Hyde's 'Hist. Relig. Veterum Persarum'; Brunet, 'Parallèle des Religions,' 4to., tome i., p. 69; Gebelin's 'Monde Primitif'; Selden 'De Diis Syriis'; Mallet, 'North. Antiq.'; Brucker's 'Vedam,' tom. v. and vi.; Bryant's 'Analysis,' vol. iii.; Anquetil du Perron's 'Zendavesta,' 4to., 1771; Maximus Tyrius, dissert. 38, 'On Serpent Worship of Antient India.'

To the works incidentally mentioned on the subject of this article may be added—Michael Psellus, 'De Operatione Dæmonum,' 1615; M. Illyricus, 'Demonstrationes de Essentiâ Imaginis Dei et Diaboli,' 1569; Peter Viret's 'Devil let loose,' 1588; 'A Dissertation in Logic, arguing the moral, religious, and political Use of a Devil or Evil Spirit,' 1797-99, by G. Leicester; Dr. Hibbert's 'Philosophy of Apparitions,' art. 'Demon,' in Calmet's Dict.; A Comedy on the Temptation of Christ by Satan in the Desert, 1538, by John Bale, bishop of Ossory; Dissertations by Perkins, Waldegrave, Udall, Andrews, Farmer, &c. on the Combat of Jesus and the Devil in the Wilderness. De Foe's 'History of the Devil' is merely a satirical and political composition. As poetical fictions on the subject, see Milton's 'Par. Lost,' Dante's 'Inferno,' Rev. Robert Montgomery's 'Satan.'

DEVIL IN A BUSH,) vulgar names of the genus
DEVIL IN A MIST,) Nigella.

DEVIL'S BIT, the vulgar name of Scabiosa succisa.

DEVISE. [WILL.]

DEVIZES, a borough and market town, having separate jurisdiction, locally in the hundred of Potterne and Cannings, in the county of Wilts; 22 miles N.W. by N. from Salisbury, 19 E. by S. from Bath, and 89 W. by S. from London.

Before the Boundary Act, the borough of Devizes was considered to be coextensive with the parishes of St. John the Baptist and St. Mary the Virgin, including an old disparked park and the site of the antient castle; but since the passing of that act, for the purposes of parliamentary representation, the town extends into the chapelry of St. James and into the parish of St. Rowde, which adjoins that chapelry.

In antient records this place is called Divisæ, De Vies, Divisis, &c. The origin of the name seems to be a supposition that this place was divided by the king and the bishops of Salisbury.

In the reign of Henry I. a spacious and strong fortress was erected here by Roger, the wealthy bishop of Salisbury, which his nephew Nigel, bishop of Ely, garrisoned with troops and prepared to defend until the expected arrival of the Empress Matilda; but Stephen having besieged it, declared that in the event of its not surrendering, he would hang the son of Bishop Roger on a gallows which he had erected in front of the castle. On this being made known to Nigel, he surrendered the fortress, together with all the bishop's treasures, amounting to the sum of 40,000 marks. This castle was afterwards seized by Robert Fitz-Herbert, on pretence of holding it for Matilda, but on her arrival he refused to deliver it up, and was subsequently hanged as a traitor to both parties. About the end of the reign of Edward III. the castle was dismantled, and the site has lately been converted into pleasure-grounds.

It appears from Leland, who calls it 'The Vies,' that in the reign of Henry VIII. Devizes was celebrated for its market. It was besieged by Sir William Waller in the parliamentary war, but just as the royalists were preparing to capitulate, Lord Wilmot, who had been dispatched by the king from Oxford, appeared on Roundaway Hill, with 1500 horse and two pieces of artillery. Sir William withdrew his forces from the town, and immediately attacked Lord Wilmot, but was totally discomfited and obliged to fly to Bristol, having lost a considerable number of men, together with all his cannon, baggage, and ammunition.

The first charter of incorporation was by the Empress Matilda, granting to her burgesses 'De Divisis' freedom of toll throughout all England and the ports of the sea. This charter was successively confirmed by all the Henrys and the Edwards. The present governing charters were granted by James I. and Charles I. The corporation have power to hold a Court of Record on Friday for debt or damage not exceeding 40*l*. The quarter sessions of the county are held here in rotation with Salisbury, Warminster, and Marlborough. Petty sessions are held quarterly before the mayor, recorder, and justice, or any two of them.

Devizes returned members to the parliaments of Ed-

ward I., to two of Edward II., and constantly since the 4th of Edward III. The revenue of the corporation is only 434*l*. per annum.

This town is situated nearly in the centre of the county, on the Kennet canal: it consists of several streets, well paved and lighted with gas, and contains many good houses. There are no buildings of any consequence, except the town-hall and the churches. The former is a handsome modern building, in the basement of which a cheese-market is held.

The parishes of St. John and St. Mary the Virgin form a united rectory, in the archdeaconry and diocese of Salisbury; the net revenue of which is 518*l*. per annum. St. John's church is built partly in the Norman style and partly in the later English style of architecture, with a square embattled tower, and consists of a nave, transept, chancel, and two chantry chapels. The chancel is very handsome, and the tower is supported by two circular and two pointed arches enriched with foliage and mouldings of different periods. St. Mary's is situated in the north-eastern part of the town. The chancel is supposed to have been built soon after the Conquest, but nearly all the rest of the structure was rebuilt by William Smyth, who died in 1436. There are places of worship for the Society of Friends, Baptists, Independents, Presbyterians, and Wesleyan Methodists.

The woollen manufacture, once of considerable importance, is now extinct. There are at present three manufactories of silk, which afford employment to about 400 persons: the weaving of crape and sarsnet is on the increase. The malting business is carried on to some extent, and there is a large snuff manufactory. The market is on Thursday, and is the largest in the west of England for corn. A large cross, which is said to have cost nearly 2000*l*., was erected, in 1815, in the market-place by Lord Sidmouth, for many years member for and recorder of the borough. Fairs are held, on the 4th February for horses; Holy Thursday and April 20th, for cattle; and June 13th, July 5th, and October 2nd and 20th, for cattle, hops, cloth, &c. Devizes contains 1200 houses, and 6367 inhabitants. At the first election after the passing of the Reform Act there were 277 registered voters.

A national school was erected at the expense of John Pearse, Esq. There is a charity school called the 'Boar Club School,' in which 40 boys are instructed and clothed for three years, and then apprenticed to various trades, &c. There are also schools on the Lancasterian system and infant schools.

Richard of Devizes, a Benedictine monk of the twelfth century, who wrote a chronicle of English history, was a native of this place.

DEVONPORT, formerly called Plymouth Dock, in the parish of Stoke Damerall, hundred of Roborough, and county of Devon, 218 miles west by south from London, and one mile and a half from Plymouth.

Devonport owes its present importance to a naval arsenal established there in the reign of William III., under the name of Plymouth Dock, which name it retained till 1824, when the appellation of Devonport was conferred on it by royal permission. It was first fortified in the reign of George II., but the fortifications were considerably enlarged and improved under an act passed in the 21st year of the reign of George III. The government of the town is vested in Commissioners, among whom are the lord of the manor, who holds courts leet and baron at Michaelmas, the stewards of the manor, the rector of the parish, the commissioner of his majesty's dock-yard, the port-admiral, the mayor, aldermen, and recorder of the boroughs of Plymouth and Saltash, the manorial lords of East Stonehouse, and of East and West Anthony; with the stewards of those manors. These commissioners have the superintendence of all the affairs of the poor, the lighting, watching and cleaning of the town, and the granting of licenses to porters and watermen.

Petty sessions are held by the county magistrates every Wednesday in the town-hall, for the despatch of business connected with the town and parish.

Devonport was enfranchised by the 2nd William IV. chap. 45, and since the passing of that act returns two members to parliament. The parliamentary borough includes, in addition to the town of Devonport, the whole of the parish of Stoke Damerall and the township of Stonehouse. At the first election after the passing of the Reform Act,

there were 1777 persons registered. We understand that the inhabitants of the borough have recently petitioned the king to grant them a charter of incorporation, which petition is now before the Privy Council. (March 1837.)

Devonport is situated at the south-west corner of the county, and is bounded on the south and west by the mouth of the river Tamer, which forms the spacious harbour of Hamoaze; and on the east by Stonehouse creek. The streets are wide and regular, well paved, and lighted with gas; the footpaths are made of marble obtained in the neighbourhood. The houses are generally large and well built. The Fore-street is approached from the east through a handsome gateway, where there is a fosse and a draw-bridge, and forms a thoroughfare to the dock-yard. A wall, twelve feet in height, called 'the king's interior boundary wall,' defends the town on the north-east and south sides; and the heavy batteries on Mount Wise protect the entrance from the sea. Without the wall is a line, or breastwork, with a fosse excavated in the solid rock from twelve to twenty feet deep. There are three gates in the line, the north gate, the state barrier, and the Stonehouse gate. A promenade, called Richmond Walk, was recently made near the sea-shore under the direction of the duke of Richmond when master-general of the ordnance.

There is a small theatre, a subscription library, and a spacious and elegant assembly-room at the royal hotel, where balls are held. To the south of the town are convenient hot, cold, shower, vapour, and swimming baths. The water which supplies the inhabitants is brought from Dartmoor in a circuitous line of about thirty miles to a reservoir on the north side of the town, from whence it is conveyed in pipes to the different houses.

The town-hall is a spacious and handsome building, with a Doric portico. It contains a county-meeting room seventy-five feet by forty, a watch-house, temporary prison, engine-house, &c. Near it is a fluted column of the Doric order, to commemorate the naming of the town in 1824, from the top of which there is a splendid view of the harbour and the neighbouring scenery. To the south of the town are the port-admiral and the governor's houses, the telegraph, and the Grand Parade. Thirty-two telegraphic stations connect this place with the Admiralty in London; and it is said that on the occasion of Napoleon surrendering to the Bellerophon the news was known in the metropolis fifteen minutes after it was known in Devonport.

The dock-yard, one of the finest in the world, comprises an area of seventy-one acres. Within the yard is the basin, constructed in the reign of William the Third, and the dock sufficiently capacious for the reception of a seventy-four gun ship, as well as four building-slips, and three other docks, one of which, the new north dock, is 260 feet by 85 feet, and 27 feet 8 inches deep. The 'blacksmith's shop' is a building 210 feet square, containing 48 forges, the fires of which annually consume 1300 chaldron of coal. Several hundred of anchors, some weighing five tons each, are piled up on the wharf in front of this building.

The 'rigging-house,' is a splendid edifice 480 feet in length, and three stories high; it forms one side of a quadrangle, the area of which is entirely composed of stone and iron, and is called the 'combustible storehouse.' Our limits will not permit us to describe one half the objects of interest that are contained within the precincts of this dock-yard, and we must content ourselves with merely mentioning the boiling-house, the mast-house, the mast-pond, and the rope-houses. The rope-houses are limestone buildings 1200 feet long, parallel to each other, and two stories high. Cables are made here, 100 fathoms in length, and measuring in circumference 25 inches; a cable of this size weighs 116 cwt. 1qr. 6 lbs., and costs 404*l*.

The immense roofs over the docks, being on the span of an arch without a buttress, are extraordinary specimens of architectural skill; the area of one of them amounting to 1 acre 39 poles and 200 feet. The harbour of Hamoaze is four miles long and half a mile broad; its greatest depth at high water is about 20 fathoms, and at low water 15. [PLYMOUTH.]

A chapel has recently been erected by government in the yard, the chaplain of which receives, in addition to a stipend from government, twopence per month from the pay of each of the officers and seamen belonging to ships laid up in ordinary. There are two episcopal chapels of

ease at Devonport, St. Aubyn's, erected 1771, and St. John's, erected in 1799. The inhabitants have also access to the dock-yard chapel. There are places of worship for Baptists, Independents, Wesleyan Methodists, and Moravians. A classical school was established by subscription in 1821, and a public school for boys in 1808; over the latter is a school for girls, where about 100 are educated and clothed. The Baptists and Methodists have also their respective schools. A public dispensary for this town and East Stonehouse was erected in 1815, and a Savings' Bank in 1829.

Devonport is a branch of the port of Plymouth. [PLYMOUTH.] There is a market on Tuesdays, Thursdays, and Saturdays, well supplied with provisions of all kinds. To the south of Devonport is a ferry to Mount Edgcombe, and to the north-west, one to Torpoint. The population is returned with the parish, and in 1831 consisted of 34,883 inhabitants, of whom 19,466 were females.

DEVONSHIRE, a maritime county in the south-west part of England. Its form approximates to that of an irregular quadrangle, having for its angles, on the west, Hartland point on the Bristol channel; on the north the boundary of Devonshire and Somersetshire, near Oare, on the coast of the same channel; on the east the boundary of Devonshire and Dorsetshire, on the coast of the English channel, near Lyme Regis; and on the south Prawle Point, near the Start Point, on the coast of the English channel. The county is bounded on the north and north-west by the Bristol channel; on the north-east by Somersetshire; on the east by Dorsetshire; on the south-east and south by the English channel, and on the west by Cornwall, from which it is separated, along part of the boundary line, by the river Tamer. There is an insulated portion of the county inclosed between Dorsetshire and Somersetshire, and the boundaries, as given above, include an insulated portion of Dorsetshire which is entirely surrounded by Devonshire. The length of this county from north to south is about 71 miles; the breadth from east to west about 68. The area of the county is stated by Mr. Arrowsmith at 2580 square miles, and in the population returns at 2585: the aggregate areas of the parishes give 1,636,450 acres or about 2557 square miles. The population in 1831 was 494,478, giving 191 or 193 persons to the square mile according as we adopt the highest or lowest estimate of the area. Devonshire is the third English county in respect of size, being exceeded only by Yorkshire and Lincolnshire, and the fourth, in respect of population, being exceeded by Yorkshire, Middlesex, and Lancashire. Exeter, the capital, is 160 miles from London in a straight line W.S.W.; 164½ miles by the shortest road, through Staines, Basingstoke, Andover, Amesbury, Mere, Wincaunton, Ilminster, and Honiton; 173 miles by the Exeter mail-road, through Staines, Andover, Salisbury, Shaftesbury, Yeovil, Crewkerne, Chard, and Honiton; 176 by the Penzance and Falmouth mail-road, through Salisbury, Blandford, Dorchester, Bridport, and Honiton; or 193 miles by the Devonport and Plymouth mail-road, through Reading, Devizes, Bath, Wells, Bridgewater, Taunton, and Collumpton.

Coast-Line, Islands.—The coast of the Bristol channel which bounds Devonshire to the north and north-west is for the most part steep and rocky. On the side towards Somersetshire, the coast-line runs nearly east and west for about 22 miles, measured in a straight line from the border of Somersetshire to Bull Point, west of Ilfracombe; along one part of this line there are cliffs, in the other parts the coast, though steep, is not broken or precipitous: there are no marked headlands. From Bull point to Morte point (distant a mile and a half south-west) the coast forms a small bay (Rockham bay) bounded by cliffs; from Morte point to Baggy point, distant three miles and a half south by west, it forms a larger and deeper bay (Morte Bay), with cliffs at each extremity and a low shelving beach in the middle. From Baggy point to Hartland point (distant 14 or 15 miles south-west) the coast forms the deep bay, Barnstaple or Bideford Bay, into which the united stream of the Torridge and the Taw empties itself. From Baggy point to the æstuary of the Taw and Torridge, except near Baggy Point, the coast is shelving and sandy, with a multitude of sand-hills, called Braunton barrows; from the æstuary of the rivers to Hartland point the coast is lined with steep cliffs and rocks. From Hartland point the coast, still lined with cliffs, runs south or south by west for about eight miles to the border of Cornwall. This coast pre-

sents, in several places, very picturesque views, especially about Lymouth, or Lynmouth (the mouth of the river Lynn), on the border towards Somersetshire, and at Clovelly, in Bideford Bay.

The coast of the English channel, which bounds the county on the south, runs W.S.W. from the neighbourhood of Lyme Regis (in Dorsetshire), 22 miles measured in a direct line, to the mouth of the river Ex. This coast is lined with cliffs throughout its whole extent, and is marked by one headland, Beer Head, at the western extremity of Seaton Bay. The rivers Axe and Otter enter the sea in the course of this line. From the mouth of the Ex the coast, lined with cliffs, runs S.S.W. six miles to the mouth of the Teign, and from thence five miles south or south by east to the headland called Hope's Nose, at the northern extremity of Tor Bay. Tor Bay is a deep bay bounded on the south by Berry head (distant about five miles from Hope's Nose), having a shelving beach at the bottom of the bay, interrupted by a bluff headland (Roundham Head), and an abrupt coast towards each extremity. Tor Bay is memorable as the place in which William prince of Orange, afterwards William III., landed at the Revolution of 1688. Berry head appears to have been the Promontorium Hellenis of the antients (Richard of Cirencester). From Berry head the coast, still possessing the same bluff character, runs S.S.W. five or six miles to the mouth of the Dart, from thence to the Start point, nine miles further; it forms a wide shallow bay (Start bay), lined with a high sandy beach (Slapton sands) that intercepts the flow of the waters which descend from the interior toward the sea, and has formed a lagoon (Slapton Lee) similar to the étangs of Gascogne or Languedoc. From Start point a high rocky coast runs W.S.W. four miles to Prawle point, the southern extremity of the county, and thence three miles west by north across the wide æstuary of the Kingsbridge river to Bolt Head (430 feet high), and thence four or five miles further in the same direction to Bolt Tail. From Bolt Tail the coast, still for the most part lined with cliffs, runs W.N.W. to the entrance of Plymouth Sound, distant 12 miles in a straight line from Bolt Tail. This interval is partly occupied by the wide and shallow Bigbury bay, into which the rivers Avon or Aune and Erme flow, and by the mouth of the river Yealm. About two or three miles of coast on the west side of Plymouth sound belong to Devonshire. Plymouth sound is three miles wide and extends many miles inward. It receives from the north-west the Tamer (united with the Lynher or St. German's river), upon the æstuary of which, called Hamoaze, is the town of Devonport, formerly 'Dock,' the royal dock-yard of which ranks next in importance to that of Portsmouth; and from the north-east the Plym, the æstuary of which is called Catwater. Mill bay and Sutton pool are small inlets at the bottom of Plymouth sound; the latter is almost encircled by the town of Plymouth. Plymouth sound, with the æstuaries of the streams that run into it, forms one of the finest harbours in Great Britain for extent and safety. It is secured from the heavy swell, which formerly set into it, by a breakwater, nearly a mile long, which extends across the middle of the sound. [PLYMOUTH.]

The Devonshire coast may be estimated at from 155 to 160 miles; 55 to 60 miles on the Bristol channel and about 100 miles on the English channel.

Lundy Island, in the Bristol channel, 10 to 11 miles N.N.W. of Hartland point, is a mass of granite two miles and a half long from north to south and about a mile from east to west. Its area is about 900 to 1100 acres. It is surrounded on every side with rocks; the landing-place, up which two men can scarcely walk abreast, is on the eastern side. The southern point is occupied by a light-house. Rat Island is a rocky detachment from Lundy Island on the south-east or south. The northern part of Lundy Island rises considerably above the level of the sea, the highest part being 200 feet high. Several brooks flow from the higher ground into the sea. Considerable plantations have been formed on the island, but the trees are too exposed to keen north-easterly winds to flourish; in the south part of the island the soil is said to be pretty good. There is an abundance of puffins and rabbits, and the island is much infested with rats. Of the number of inhabitants we have no account: they must be very few; for in 1794 there were seven houses and 23 inhabitants, and in 1822 only two houses beside the residence of the light-house keeper. Their principal business is shooting rabbits for their skins, and puffins for their fea-

thers. There are the remains of a fort with a few dismounted guns commanding the landing-place: also the ruins of a chapel, dedicated to St. Ann. St. Nicholas Island is in Plymouth sound: it is fortified.

Surface, Hydrography.—Devonshire is more uniformly hilly than any other of the large counties of England. The principal ranges of hills may be considered as offsets from the elevated districts of Dartmoor, Exmoor, and Blackdown. Dartmoor is a granitic table-land, having its greatest elevation towards the north, and containing the highest ground in Devonshire. Cawsand or Cawsorn hill, in the northern part of the forest, is 1792 feet high: Rippon Tor, four or five miles north of Ashburton, 1549 feet: Butterton hill, in the south part of the forest, 1203 feet: the head of the river Erme 1131 feet; and the site of Harford or Harford church, also near Butterton, 658 feet. These heights are from the Ordnance Survey, except the last, which is given on the authority of Dr. Berger.

Dartmoor extends nearly 22 miles from north to south (from Belston, near Oakhampton, to the Plymouth road between the rivers Erme and Avon or Aune); and 14 miles from east to west, from the neighbourhood of Moreton Hampstead to that of Tavistock. This immense waste is thus described by Dr. Berger (*Geol. Trans.*, vol. i., p. 119): 'From Harford church (near the southern limit of Dartmoor) the country assumes quite a bare and alpine appearance, presenting a vast plain, extending beyond the visible horizon. The face of the country is formed by swellings and undulations gradually overtopping each other, without ever forming distinct mountains. There is neither vegetation nor any human dwelling; we tread upon a boggy soil of very little depth, and scarcely affording sufficient food to support some dwarf colts as wild as the country they inhabit.' The area of Dartmoor forest has been estimated at 80,000 (Fraser, *Agric. Report*) or 100,000 acres. Part of the waste is appropriated by the surrounding parishes, the freeholders of which possess the right of common, or as it is termed the right of *venville*, on these appropriated parts. The rest of Dartmoor, to which the name of Dartmoor forest (frequently given to the whole waste) strictly applies, and which belongs to the duchy of Cornwall, has been found by survey to contain 53,644 acres. It was on this part that the prison was built during the last war for the prisoners of war. The highest part of Dartmoor forest, in which some of the most important rivers of the county (the Taw, the Dart, the Teign, &c.) have their rise, consists of a succession of morasses formed by the decay of the successive crops of aquatic plants, with which this part teems: these morasses are in some parts 40 to 50 feet deep, in others not more than 5. In several places there have been land-slips, owing to the over-accumulation of marshy soil: these slips would be more frequent but for the granite rocks or 'tors' which continually rise to the surface. Peat is dug in this forest; and many sheep pastured there in summer, and some all the year round. The elevation of Dartmoor forest causes it to have a much lower average temperature than other parts of the county. The average difference of the temperature at Ilfracombe, on the north coast of the county, and Oakhampton, just on the northern border of Dartmoor, is 10° 5' of Fahrenheit: in summer the difference is small, but in winter it rises to 16° or 18°. (Vancouver's *Agric. Survey*.) Amicombe hill, Okement hill, and others, are elevated parts of Dartmoor. Brent Tor (802 feet, according to Dr. Berger,) and Blackdown, both near Tavistock, border upon Dartmoor, but are not composed of granite.

Dartmoor has been described as an elevated plain: the descent to the lower country all round is rapid. With the exception of Blackdown, there is no eminence near it which comes within 800 or 900 feet of its highest point. From Dartmoor several ranges of hills, composed chiefly of rocks of the transition series, branch off; one from the north-west part of it, near Oakhampton, runs in the direction of Hartland point, dividing the basin of the Tamer from that of the Torridge, and sending out branches which separate the valleys of the various feeders of the Tamer. This range has no remarkable elevations: part of it, with one of its branches, has the name of Broadbury. Another branch running northwards separates the valley of the Okement, and afterwards of the Torridge, from that of the Taw, and terminates near the junction of these last two rivers. Another branch runs eastward towards Exeter, turns to the south-south-east near that city, and separates the valleys of the Ex and the Teign. Little Haldon, in this range, near its termination, has an

elevation of 818 feet. A branch which this range sends off soon after leaving Dartmoor, runs north-eastward, separates the basin of the Ex from that of the Taw, and connects the heights of Dartmoor with those of Exmoor. Another range running south-east from Dartmoor separates the valleys of the Teign and the Dart: Furland hill, in this range between Brixham and Dartmouth, is 589 feet high.

Exmoor is a tract of high land, having its greatest elevation towards the north. It is composed of rocks of the transition class, and is chiefly included in Somersetshire, but extends into the north and north-east parts of Devon. Its highest point, Dunkerry beacon, Somersetshire, attains to the height of 1668 feet, according to the Ordnance Survey, or according to another measurement, 1784 feet. A range of hills extends from Exmoor along the north coast of Devonshire to Morte Bay; some of the summits are probably 1000 feet high: the village of Linton on this range, at the mouth of the river Lynn, is 428 feet high. The ridges of Exmoor forest and the branches which it sends off towards the south separate the valleys of the upper waters of the Ex.

A third system of hills consists of Blackdown, in the eastern part of the county, on the border of Somersetshire, between Taunton and Honiton; and of the ranges of hills which it sends off, chiefly to the southward, separating the basin of the Otter from those of the Ex on one side, and the Axe on the other, and dividing from each other the valleys watered by the several affluents of the Otter and the Axe. Dumpdon hill, north-west of Honiton, is 879 feet high. These hills have flat tabular summits; their steeper side is toward the west. [CRETACEOUS GROUP.]

Rivers.—The rivers of Devonshire are numerous, and some of them important. The Ex rises in Exmoor, in Somersetshire, and flows south-east past the villages of Exford and Winford to Exton, where it turns to the south, and reaches the border of Devonshire about 18 or 19 miles from its source. For about two miles it divides Devonshire from Somersetshire, being joined in this part by the river Barle, which also rises in Exmoor, and has a south-east course of 22 to 24 miles through Somersetshire before it falls into the Ex. A little below the junction of the Barle, the Ex enters Devonshire, and flows in a southerly direction, but with a very circuitous course, to Tiverton (about 10 or 11 miles), receiving in its way several feeders, of which the chief are the Batham (9 or 10 miles long), which flows from the border of Somersetshire past Bampton, and falls into the Ex on its left or eastern bank; and the Loman (8 or 10 miles long), which flows from the hills on the Somersetshire border, near Bampton, and joins the Ex on its left bank at Tiverton. From Tiverton the Ex flows still southward, 13 miles, to the junction of the Culm, receiving by the way, on its right bank, the Dart (8 miles long) from the moors between Tiverton and South Molton; and about 2 miles lower down, on its right bank, the Creedy (16 miles long), which passes near Crediton, and is joined by the Yeo (12 or 13 miles long) below that town. From the junction of the Creedy the Ex flows between 2 and 3 miles southward to Exeter, and then about 5 miles south-east to Topsham, where it receives the Clist, 16 or 18 miles long: just above Topsham, the Ex becomes a tide river. The tideway of it is about 5 miles long (or 7 by the low-water channel), and about a mile wide at high water. A sand-bank, dry at low water, divides its mouth into two channels. The whole length of the Ex is from 57 to 60 miles. A canal, formed in the reign of Henry VIII., runs by the side of this river between Exeter and Topsham: this canal was originally more than 3 miles long, and it has been lately lengthened so as to enter the tideway lower down. By this canal and the tideway of the river, vessels can get up to Exeter, above which the river is not navigable.

The Culm, mentioned above, rises in the Blackdown hills, just within the border of Somersetshire, and flows 11 miles westward to the village of Uffculm; from thence 5 miles south-west to the town of Collumpton or Cullumpton, and from thence for 10 miles south-west (26 miles in all) into the Ex.

The Torridge rises on the border of Devonshire and Cornwall, near the head of the Tamer [CORNWALL], and flows eastward about 7 miles to the neighbourhood of the villages of East and West Putford; it then turns to the south-east, and runs 8 or 9 miles to Bradford Mill, where it receives the Waldon (12 miles long) on its right bank.

From Bradford Mill it runs eastward 9 miles past Sheepwash or Shipwash to the junction of the stream (10 or 12 miles long) which passes Hatherleigh; and thence $1\frac{1}{2}$ mile north-east to the junction of the Okement, which is formed of two brooks (East and West Okement) that rise on Dartmoor and unite at Oakhampton, and has a northward course of 18 to 20 miles. From the junction of the Okement the Torridge has a very sinuous course of 25 or 26 miles in a north-west direction, past Torrington to Bideford, where it becomes a tide river. The tideway from Bideford to Appledore, where the Torridge and the Taw unite, is 3 miles, making the whole course of the Torridge 53 to 56 miles. The Torridge is navigable for vessels up to Bideford, and for boats to Wear Giffard, 4 or 5 miles higher up.

The Taw rises on Dartmoor, on the slope of the same hill (Okement Hill) from which the East and West Okement rise, and has a northward course of 17 or 18 miles to below the mill and village of Brushford: from thence it has a winding course of nearly 7 miles in a north-north-west direction to the junction of the Little Dart (16 or 18 miles long), which rises in the range of hills connecting Dartmoor with Exmoor, and flows westward past Chumleigh into the Taw. From the junction of the Little Dart, the Taw flows northward 3 miles to the junction of the Mole (20 miles long), which rises on North Molton ridge, Exmoor, on the border of Devonshire and Somersetshire, passes North and South Molton, and after receiving the Bray (14 miles long), which also rises on Exmoor, joins the Taw on its right bank. After the junction of the Mole, the Taw flows north-north-west 16 miles to Barnstaple, where it becomes a tide river. The tideway is about 5 miles in length from Barnstaple to the junction of the Torridge, making the length of the Taw nearly 50 miles. It is navigable for small vessels up to Barnstaple, and for boats to New Bridge, 3 or 4 miles higher. The æstuary of the united rivers Taw and Torridge is not 2 miles long.

The Dart rises on Dartmoor. The head of the East Dart, which may be considered as the true head, is on the southern slope of Okement hill, near the springs of the Okement and the Taw. It flows 10 miles south-east to the junction of the West Dart (9 miles long) at Dartmeet Bridge, between Ashburton and Tavistock. From Dartmeet Bridge the river flows south-east 30 miles past Buckfastleigh and Totness, to its outfall just below Dartmouth. Its whole course is thus about 40 miles. The tide flows up to Totness 10 or 11 miles from the mouth of the river: above this place the river is not navigable. The navigation is chiefly used to convey coal and shelly-sand manure to Totness and the neighbourhood, and to export the produce of the tin, lead, and copper mines, worked on the border of Dartmoor Forest. The entrance to the river forms a good harbour.

The Teign (the North Teign) rises on Dartmoor near the head of the Dart, and after flowing three or four miles to the north, turns eastward, and flows about 14 miles to Dunsford, between Exeter and Moreton Hampstead. It then runs south about 12 or 13 miles, near Chudleigh, receiving by the way the West Teign or Bovey river (15 miles long) from North Bovey, to the neighbourhood of Newton Bushel and Newton Abbot; below Newton Bushel it has an eastward course of five miles (chiefly tideway) into the sea at Teignmouth. Its whole course is about 35 miles: it is navigable up to Newton Bushel, five miles from the mouth.

The Otter rises on the southern slope of Blackdown, near the village of Otterford, and flows south-south-west about 25 miles, past Honiton, Ottery St. Mary, and Otterton, into the sea about five miles east of the mouth of the Ex. It is not navigable, and has no tributary worthy of note. The Axe rises in Dorsetshire, not far from Beaminster, and has a circuitous course (north-west, west, and south-west) of 16 miles, through Dorsetshire, Somersetshire, and Devonshire, to Axminster. Below Axminster it flows 7 or 8 miles south-south-west into the sea at Axmouth, receiving the Yart (12 or 13 miles long) from the hills adjacent to Blackdown.

The Avon or Aune, the Erme, and the Yealm rise on the southern side of Dartmoor, and flow southward into the sea between Plymouth Sound and Bolt head. They are respectively 22, 15, and 14 miles long. The Aune and the Yealm have each a navigable tideway of three miles, the Erme of two miles. The Plym rises near the Erme, and flows south-south-west 16 or 17 miles into Plymouth Sound at Plymouth. Its tideway 'Catwater' is three miles long.

The Tamer, which divides Cornwall from Devonshire, has been already described. [CORNWALL.] Its principal Devonshire feeders are the Deer (9 miles long), which flows past Holsworthy; the Carey (13 miles long), and the Lyd (13 miles long), which rises on Dartmoor; both these join the Tamer near Launceston; and the Tavy or Tay (26 or 28 miles long), which rises on Dartmoor, and flows past Tavistock. The Tavy joins the tideway of the Tamer, and has itself a tideway of more than three miles. The Lew Water (nine miles long) and the Thistle Brook (10 or 11 miles long) are feeders of the Lyd; and the Wallcomb (13 miles long) is a feeder of the Tavy. There is a picturesque fall in the Lyd, near Lidford, four or five miles from its source.

The other rivers of the county are too small to require particular notice. It will suffice to mention the Lynn (10 miles long) on the north coast, and the Sid (6 miles long) on the south coast. Salcombe harbour, between Bolt head and Prawle Point, is the æstuary of several small streams, to which the maps do not assign a name. This æstuary is navigable up to Kingsbridge four miles from the mouth.

Canals.—The Bude and Holsworthy canal, with which is connected the Bude and Launceston canal, enters this county from Cornwall, near the head of the Tamer, and proceeds in a very circuitous course of more than 15½ miles to Thornbury on the river Waldon, one of the feeders of the Torridge, where the canal terminates. It has two inclined planes in Devonshire and two in Cornwall: part of its course is through a tunnel. The chief purposes of this canal are to facilitate the importation of Welsh coal, and to convey shelly sand from the coast to the interior for manure. In Nichols' and Co.'s Map of Canals, one is marked as extending from Torrington along the valley of the Torridge for about four miles, and opening into that river at Wear Giffard, between Torrington and Bideford, where the navigation of the river begins. The Stover or Teigngrace canal is connected with the Teign at Newton Bushel, and extends about four miles up the valley of that river toward Bovey Tracey: it serves for the importation of coal, culm, sea-sand, and lime; and the exportation of Bovey coal, pipe-clay, and potters' clay. The Tavistock canal extends four miles from Tavistock to the tideway of the Tamer; it has a tunnel one mile and a half long, and a branch two miles long, to Millhill slate-quarries. The Exeter canal has been noticed. Two important canals have been projected, 'the Grand Western Canal' (Acts obtained A.D. 1796, 1811, 1812), from Taunton in Somersetshire, by the valleys of the Tone, the Culm, and the Clist, to Topsham; with branches to Tiverton and Collumpton; and 'the English and Bristol Channels Ship Canal' (Act obtained A.D. 1825), from Bridgewater Bay to Beer Road in Seaton Bay at the mouth of the Axe, crossing the eastern extremity of Devonshire by the valley of the Axe.

There is a railroad from Dartmoor, near the prison originally built for prisoners of war, to the river Plym near Plymouth: a branch from Catdown and Sutton Pool, close to Plymouth, joins this railroad at its termination on the Plym. The length of the railroad and branch together is about 25½ miles. Another railroad, 8 miles long, formed of granite blocks, extends from the Haytor quarries to the Teigngrace canal. Railways have been projected between Bristol and Exeter, passing by Axminster, Taunton, Bridgewater, &c.; and between Exeter and the Southampton railway at Basingstoke, Hants. An act of parliament has been obtained for the former of these.

There are no less than four roads between London and Exeter traversed by the mails. The Devonport, Exeter and Bath mail-road enters this county between Wellington and Collumpton, and passes south-west through Bradninch to Exeter, and from thence by Chudleigh, Newton, and Totnes to Devonport. The Exeter mail-road enters Devonshire between Chard and Honiton, from which place it runs to Exeter. The Penzance, Falmouth, and Exeter mail-road enters Devonshire between Bridport and Axminster, and proceeds by the latter town and Honiton to Exeter, and from thence by Oakhampton, skirting the north side of Dartmoor, to Poulston Bridge, where it crosses the Tamer into Cornwall. The Falmouth, Devonport, and Exeter mail-road enters the county between Ilminster and Honiton and runs to Exeter, and from thence by Chudleigh and Ashburton to Plymouth and Devonport, and from whence the mail is conveyed across the æstuary of the Tamer into Cornwall. A mail-road from Bristol to Bideford enters Devon-

shire between Wivliscombe and Bampton, and runs by South Molton and Barnstaple to Bideford. A road from Exeter runs by Crediton and Chumleigh to Barnstaple, and from thence by one branch to Ilfracombe, and by another to Combe Martin. From this road, at or near Crediton, are branches to Tiverton and Bampton and South Molton on the one hand, and to Oakhampton on the other; and between Chumleigh and Barnstaple another road branches off to Bideford, Clovelly, and Hartland. Besides the mail-road from Exeter to Plymouth, there is a road through Moreton Hampstead, and over Dartmoor. A road from Ashburton leads to Tavistock over Dartmoor.

Geological Structure.—A few spots occur in the eastern portion of the county and along the coast between Sidmouth and the border of Dorsetshire, which are occupied by outlying portions of the chalk formation. The sections of these portions on the coast present the last chalk cliffs toward the west. In the cliffs eastward of the Axe, the chalk does not occupy the whole cliff but only the upper portion: the central part of the cliff is composed of green-sand, and the lower part of the lias: for the chalk and green-sand in their extension westward overlie the other formations, which elsewhere are found beneath them and rest immediately upon the lias. Westward of the Axe, where the chalk cliffs reappear, the chalk dips rapidly towards the west: a portion of the upper part of the cliff has been detached and has subsided toward the beach, the shattered mass of chalk exhibiting a variety of picturesque forms.

The green-sand formation presents on the confines of Dorset and Devon many outlying masses forming considerable hills. To this formation belong the flat-topped hills of Blackdown, the range connected with them which separates the valleys of the Otter and the Axe, and the branches of this range which separate the smaller valleys watered by the tributaries of the Axe (the Yart, the Coly, &c.) and by the Sid. A range extending westward from the Blackdown hills, and bounding the valley of the Culm on the north, also belongs to the green-sand formation: and beyond Exeter the range of the Haldon hills, divided only by the valley of the Teign from the granite of Dartmoor, is capped by green-sand; thus affording a remarkable instance of the approximation of primitive rocks and those of much later formation. The green-sand heights in Devonshire are for the most part in the state of unreclaimed heath. [CRETACEOUS GROUP.]

On the eastern side of the Blackdown and connected ranges, the green-sand rests upon lias, the lowest of the oolitic series of formations. Lias occupies the valley of the Axe above Axminster, and the upper part of the valley of the Yart. On the western and southern sides of Blackdown the green-sand overlies all the oolitic formations, and rests immediately upon the red marle, which, with the accompanying sandstone and conglomerate, constituting the formation designated the new red sandstone, occupies the tract from the Blackdown hills westward to the valley of the Loman and the Ex: it constitutes the bed of the Loman, but extends not quite to the bank of the Ex, which flows for the most part over a bed of transition rocks. Between Silverton and Exeter the red marle is found extending westward across the Ex and the Creedy, and along the valley of the Yeo, nearly to the valley of the Taw. It extends southward from the Blackdown hills along the valley of the Otter and across the country between the Otter and the Ex to the coast; crosses the Ex immediately below Exeter, and extends along the coast with some interval to Torbay: it forms the valley of the Sid and the Coly, and the lower part of the valleys of the Axe and the Yart. The green-sand which caps the Haldon hills rests chiefly on this formation. Between Exeter and the village of Exminster the layers of red and white sand in this formation are strangely intermixed. The conglomerate which belongs to it is quarried for building at Heavitree, near Exeter. In the vicinity of Exeter, and in other places near the junction of the sandstone and transition districts, there is found amygdaloidal trap interposed between the sandstone beds.

The district occupied by the various formations enumerated above is small, compared with that which consists of the rocks of the transition class. These occupy all the county northward and westward of the new red sandstone, except the primitive district of Dartmoor. The western side of Great Haldon (green-sand) rests upon the transition rocks. These transition rocks consist of an argillaceous

slate, which in the neighbourhood of Dartmoor does not attain to an average elevation of more than 500 feet; except on the western flank of the moor, where it forms a steep eminence of more than 1100 feet. In the north of Devon it rises considerably higher, and the heights of Exmoor (which are in some parts 1800 feet high) consist of it. In this part of the county the rocks which compose the formation differ materially in their mineralogical characters: they have for the most part the structure of sandstones, and are essentially composed of quartz and clay, but in different proportions; quartz predominating in the coarser and clay in the finer grained varieties: these last graduate into a fine slate, the laminæ of which are as thin as paper. The strata of greywacke near Clovelly incline in every direction, and describe the most capricious and picturesque forms. The undulating surface of the country may be partly ascribed to the predominance of the argillaceous slate, which is, of all the rocks of earlier formation, the most subject to decomposition. These slate rocks are quarried for roofing-slates: they are metalliferous, affording ironstone; and veins of tin, copper, and lead: the veins or lodes which yield tin or copper run, as in Cornwall, from N.E. to S.W. (approaching more or less to E. and W.), and those which afford lead run nearly at right angles to these. The strata in the mining field about Tavistock which yields tin, copper, lead, and manganese, are traversed by porphyritic (elvan) beds, bearing nearly east and west. A few lead and copper mines are wrought in North Devon: the lead is combined with silver. In many parts of the transition district, beds of limestone and masses of greenstone occur. The limestone rocks in the vicinity of Plymouth, Tor Bay, Ashburton, Newton Bushel, and Chudleigh, as containing organic remains and alternating with argillaceous slate, may be referred to the transition series: the limestone is quarried for building and burnt for manure: beautifully veined marble is worked in different places. The limestone of the north of Devon which crosses the county in parallel courses E. and W., is referable to the same series. The greenstone occurs in various parts of the slate district on the northern and western sides of Dartmoor: and detached portions of amygdaloidal trap, observed in many situations round Dartmoor, may probably be referred to this formation.

It is in the transition district that the imperfect coal or lignite, called Bovey coal, is found. It occurs at Bovey Heathfield, on the right or S.W. bank of the West Teign or Bovey river in a plain where the strata of it rise to the surface. It lies in parallel seams from four to sixteen feet thick, at six or eight feet distance from each other, to the depth of sixty feet, and exhibits a gradation from the most perfect ligneous texture to a substance nearly approaching the character of pit coal. Potters' clay and pipe clay are found in the same neighbourhood. These various substances are of a later formation, and are deposited with intermingled beds in a basin formed of older rocks. The Bovey coal is used for fuel in the potteries on Bovey heath, and by the poorer people of the neighbourhood: but its difficult and imperfect combustion, and fetid gas, render it unfit for domestic use.

Granite forms the mass of Dartmoor. Numerous rifted rocks called tors, are scattered over the surface of this moor: they appear to occupy their primitive sites and to owe their present figure to the resistance which their more perfect crystallization has enabled them to offer to the influence of the atmosphere. The Dartmoor granite is remarkable for the size of the felspar crystals which it contains: it is much valued for its durability, fineness of texture, and the size of the blocks; it is quarried and exported to a considerable extent, especially to London. It is metalliferous; containing veins of tin, and even the rock itself being sometimes impregnated with this metal. (Conybeare and Phillip's *Outlines of the Geology of England and Wales*; *Geological Trans.* vol. i.; Lysons's *Magna Britannia*; *Physical and Political Geog. of the Brit. Isles in the Library of Useful Knowledge*.)

Agriculture.—The lower hills which occupy so large a part of the surface of this county are covered with grass; the higher with moor and rock. The county contains along its numerous rivers many fertile meadows, some of which are only imperfectly irrigated, and others not at all. Grass seems to be the natural produce of a mild moist climate, like that of Devonshire, in which corn is everywhere a secondary object. The improvements in the cultivation of arable land which have been rapidly introduced into other

counties, especially in the north, have not been so favourably received in Devonshire. The oldest system of Devonshire cultivation is a rude species of convertible husbandry, very different from what is called by that name in the north of England and south of Scotland. When grass land begins to wear out by injudicious management, or from a natural defect in the soil, the surface is pared thin, and the sod when dried is burnt in heaps. The ashes thus produced stimulate the soil and enable it to bear a few crops, frequently three corn crops in succession. When the land is thus nearly exhausted, it is laid down again in grass without much care, and is pastured for eight or nine years, when the same process is repeated. This system is so common in Devonshire, that the operation of paring and burning is frequently called *Devonshiring*, or contracted, *Dentshiring*. Opinions differ very much on this practice. There are soils and situations where burning may be extremely useful, by improving the texture of the soil, and destroying weeds and insects; and the practical result proves that it has its advantages. But in other circumstances the burning does harm, and reduces the soil to a state of great sterility, after having stimulated it to produce one or two crops. It is becoming less common every year, and there is no doubt but in due time it will be confined to land abounding in vegetable matter in that state in which it is not fertile, as in peat or turf.

The soil of Devonshire consists of the substance of the rocks of which the hills are composed, which are granite, grauwacke, red sandstone and slate, and marble. The decomposed slate gives the argillaceous part, which binds the silicious and calcareous sand produced from the other rocks. The waters have mixed these substances in every proportion; but the best and most fertile soils are composed of a mixture in the proportions which form a good sound loam very favourable to the growth of wheat and of potatoes. A great part of North Devon is above mediocrity as to fertility; and portions of the southern part of the county are highly productive. Considerable wastes and heaths have been gradually brought into cultivation; and although many wastes and commons still remain, and there are extensive moors and bogs scarcely susceptible of improvement, the quantity of land which is productive in grass or corn is very considerable for so hilly a country. The grass land occupies more than four-fifths of the soil under cultivation. Where an improved system of husbandry has been introduced, chiefly by resident proprietors, a regular course of crops is adopted; but the old Devonshire farmer takes three, or at least two corn crops after breaking up a pasture, and a small portion of turnips or potatoes, and has no regular rotation. After the surface is pared and burnt, lime is used for manure, and earth from banks and hedge rows, mixed with the ashes. For turnips and potatoes farm-yard dung is used. When the sod is not burnt, the land is ploughed up in autumn or in spring, cross-ploughed in May or June, then cleared of weeds which are burnt, and then limed and manured: thus a tolerable preparation for wheat is produced. In some situations where shelly sea-sand can be procured, it makes an excellent dressing for the land: 160 horse loads, or *seams*, as they are called, of $2\frac{1}{2}$ cwt. each, are mixed with 40 or 50 bushels of lime for an acre. When the soil is strong, and the land is ploughed from a state of pasture for immediate sowing with wheat, the seed is frequently covered by the hack, a kind of heavy hoe like a shipwright's adze. The furrow-slices are laid on edge in ploughing, and the wheat falls in between them; the hacking fills up the intervals, and the wheat comes up in regular rows. This is a very old mode of cultivation, and common in different parts of the Continent. If the land has been well prepared, it is a method of covering the seed preferable to harrowing it in, but it is more expensive. The practice of shovelling out the intervals between the stitches to cover the seed with the earth taken out, is common and much to be commended.

The rapid growth of weeds in the climate of Devonshire renders all the corn crops very foul, even after a good fallow. This should have pointed out the advantage of the row culture, which admits of hoeing the crops; but drilling is not yet introduced to any extent. Great expense is bestowed in hand weeding, where attention is paid to having clean crops: where this is neglected, the return is much below what might be expected from the soil.

Some of the lands on the hills are so steep that the crop must be brought home upon horses, who carry a pack-

saddle with large hooks on each side, in which the sheaves are laid. A horse so loaded looks at a distance like a little moving stack, being almost entirely covered with sheaves.

A considerable quantity of potatoes are raised in Devonshire and sent to London, where they obtain good prices. They were formerly planted in lazy-beds, as in Ireland, but the superior method of single rows moulded up is now very generally adopted. The rich brown loam on a rocky sub-soil, which gives a dry sound bottom, especially if it has been for some time in grass, whether pared and burnt, or only ploughed and well worked, produces an abundant crop of very good potatoes. An acre well cultivated and manured will give from 300 to 400 bushels of potatoes for twenty planted.

Grass land being far more abundant in Devonshire than arable, butter, cheese, and live stock may be considered as the chief agricultural produce for exportation. The finest and richest meadows are situated on the alluvial borders of the principal rivers. These ought never to be ploughed up, although this is sometimes done, especially near the end of a lease, if not prevented by a restrictive clause. When such lands are ploughed, sudden floods sometimes destroy the crops, and carry off the finest particles of the soil. Where the meadows are irrigated they are worth from 2*l.* to 3*l.* per acre, and will produce two tons of hay per acre after having been fed off till May-day. The upland meadows are less productive, and require occasional manuring. They will produce from 20 to 30 cwt. of superior hay for horses by being shut up in March. The rent of these is from 30*s.* to 40*s.* per acre. The average quality of good upland pastures, whether of old grass or newly laid down, is such as will feed a cow of 9 stone per quarter on two acres for five months, and two sheep per acre for the remaining seven. When the land has been much exhausted by corn crops, the grass seldom continues good beyond the first or second year, when it shows the mischief that has been done by the appearance of poor weak grasses which succeed the clover and rye-grass.

The clouted cream of Devonshire is a well-known delicacy. It is made by heating the milk on the hearth, or by means of a stove, to a degree a little below the boiling point, when the clouted cream rises to the top like a thick scum, and is taken off when cooled. This cream being merely stirred briskly with the hand or a stick, is converted into butter. It is universally admitted that the butter thus produced is inferior to that which is made from the cream which has risen slowly and spontaneously, and in all the largest and best dairies in the vale of Honiton the cream is never clouted, except to be eaten in that state as a luxury.

The cows used for the dairy are almost exclusively of the breed of the county, and of a red colour. They are handsomely shaped, and some of them give much good rich milk. In general however they have too great an aptitude to become fat to be good milkers. A good Devonshire cow gives three gallons of milk a day, which will make twenty ounces of butter, for the first twenty weeks after calving: after this the milk gradually decreases, till, at the end of nine months, she goes dry. Thus the average produce per cow of a whole dairy through the year will not be more than half this quantity, even if all the cows are good, which is seldom the case. Cheese is made of skimmed milk, and is consequently inferior in quality. Where porkers are in request, as near great towns, they are profitably fattened on the skim milk, or on the whey, with the addition of meal.

A great many oxen are reared and annually exported from all parts of Devonshire, but chiefly the northern parts. About Barnstaple and South Molton the best breeds are met with. The North Devon oxen are famed for their docility and activity at work, and especially for their great aptitude to fatten. They are peculiar in form, and easily distinguished from all other breeds. The breed which resembles them most is the Sussex, but the latter are coarser in the limbs and horns, and have not that peculiar colour of the muzzle and round the eyes, which marks the North Devon breed. The cows of the pure North Devon are chiefly kept to breed; for the dairy they are improved by a cross with a short horn. Some very fine cows of a mixed breed may be seen in the neighbourhood of Exeter, and along the whole vale of the Exe, fine in the coat, horn, and bone, and short in the legs. A cow bred from a North Devon by a Yorkshire bull, produced regularly twenty-four quarts of milk per day for five months after

calving, and for several years; but the milk was not quite so rich as that of the pure breed, twelve quarts producing only one pound of butter, while eight quarts of the milk of the pure Devon cow made the same quantity.

The sheep fed on the hills and wastes of this county are of a peculiar breed, with fine wool and excellent flesh. The Exmoor sheep are extremely hardy, and well adapted to cold bleak mountains. The wethers at three years old, when fatted, weigh 12 or 15*lbs.* per quarter, and the fleece from 4 to 7*lbs.* In the valleys some remarkably fine sheep of an improved breed, as far as wool and carcase are concerned, have been produced by crosses of the native sheep with the Leicester. The wet state of the low meadows is not favourable to the breeding of sheep, although they fatten rapidly on water meadow grass. The higher pastures are consequently resorted to for breeding flocks, but it requires a hardy race to withstand the wet and cold winters on the Devonshire hills; for frost is not so hurtful to lambs as continued rains. The pasture on Dartmoor Forest is very good, and the rot is almost unknown there. In order to avoid the danger of the rot, which is prevalent in the lower pastures, the sheep are often left too long exposed to the autumn rains and mists on the hills, and consequently lose much of their condition.

The following table, taken from the report of the county by Vancouver, may be interesting to the breeders of sheep.

NATIVE BREEDS.	Age of wethers, when killed, in months.	Average weight per quarter in lbs.	Average weight of fleece in lbs.	Condition of Fleece.	Comparative value of Fleece.	Rough fat in lbs.	Kidney fat in lbs.	Total inside fat.
Exmoor-horned, white legs and face, with a moderately long staple of wool, pure . . .	30	15	7	Yoak.	5 <i>s.</i> 10 <i>d.</i>	7	5	12
Dartmouth, do. do.	30	16	8	do.	6 8	8½	6	14½
South Devon nott, brown face and legs, long wool, pure	30	22	10	do.	8 4			
Bampton nott, white face and legs, short wool, pure . . .	20	22	6½	do.	5 5	10	7	17

The race of pigs in Devonshire is very good generally; and in some districts, where care has been taken to select the best animals and cross the breeds with judgment, as fine hogs are fattened as in any part of England.

The extremely prolific nature of the pig makes it an easy task to improve the breed by selection and crossing. A very few years' careful observation will enable any intelligent farmer to keep only the most profitable breeds. In less than a year the result of any cross is known; and when a hog twelve months old, and put up to fatten for three months, pays amply for his food, the farmer may be contented with the manure for his profit. But some breeds pay more than this; and the porkers fed with the offal of a dairy, often give a profit which forms a very important item in the balance of accounts. To prove this it is only necessary to look at the account of the receipts and expenses of a dairy farm as given by the reporter, p. 233, where it will be seen that out of a profit of 88*l.* 4*s.* 9*d.*, that upon pigs alone is reckoned at 25*l.*, which is almost one-third of the whole.

The land in Devonshire is held in fee or on lease for lives. Where the owner or lessee on lives grants a lease, the tenant, according to the length of his tenure, may make improvements; but where the chief lessee has an uncertain tenure, and the land is underlet at rack rent from year to year, no improvement can be expected. The practice of letting farms at a nominal rent for three lives, or for a long term, often induces a man without much capital to offer a great price for a lease which he has not the means of making profitable by good cultivation. A lease for fourteen or twenty-one years to a man who possessed an adequate capital, at a full rent, with proper restrictions to secure good cultivation, would be more likely to improve a property, and in the end would be much more lucrative both to the landlord and the tenant.

The farm buildings in Devonshire are frequently very

inconveniently situated with respect to the farm. The object seems to have been to choose a sheltered spot, without regard to the situation of the land attached to the farm.

The materials of which the buildings are constructed are stone or earth, made into a species of mortar, and formed into thick walls, which dry and harden gradually, and are called by a provincial term *cob* walls. Of this material, houses, barns, granaries, and especially garden walls are made; it is in some respects similar to the *pisé* of the south of France; but in this last no water is used, whereas the cob walls are made in a moist state, and harden by drying. If the wet is kept off by a good coat of plaster, and a projecting roof, a cob wall will last many generations.

The farms are not so extensive as in the more level parts of England; 150 to 200 acres, of which at least three-fourths are pasture, are considered a large farm. The extensive commons and wastes, where cattle can be turned out for a mere trifle, even if no common rights can be claimed, tend to increase the number of small holdings: a farm of fifty acres of grass land can maintain a great number of cattle, when they are out of it for seven months in the year.

There are also in this county many more small proprietors and lessees for ninety-nine years, which is nearly the same, than in most other parts of Britain. They are mostly frugal and industrious, and if they do not cultivate their land in the most approved manner, they at least contrive to live comfortably. This is chiefly owing to the rearing of cattle, which requires constant attention, and the eye of the master, much more than the cultivation of the soil, and in which small occupiers are generally more successful in proportion than large farmers.

The chief beverage of the Devonshire people is cider, which is here superior to any other in England. The soil on the slopes of the hills is peculiarly adapted to the growth of fruit trees, especially on a loose rocky bottom, where the roots may insinuate themselves and find moisture at all times. The fruit trees in many parts of the county give a stranger the idea of forest trees, and it is only when they are seen in blossom or covered with fruit, that an orchard could be distinguished from a wood, if it were not for the regular distance between the trees, and the grass growing under them. There are some favourite sorts of apples which have been perpetuated by grafting, at a time when it had not yet been discovered, that every variety from seed has its limited period, beyond which it cannot be continued. Most of the orchards now shew symptoms of old age, and gradually diminish in produce. A new generation of apples is much wanted, and will no doubt arise to take the place of the old. The true golden pippin and the cocagee are now nearly extinct; but many new varieties have been raised from seed, some of which may probably rival the old, if not surpass them. Another cause of the degeneracy of orchards, is the planting of young trees on the exact spot where the old trees have decayed. Although trees do not require so frequent change as herbaceous plants or shrubs, they no doubt exhaust the soil in the immediate neighbourhood of the stem, as may be perceived by examining the roots which continually spread outwards for nourishment. As a quick hedge will not grow in the bank from which an old hedge has been grubbed up, however rich and mellow the soil may appear, so a tree will not thrive on the spot where another has stood for years, unless the soil be renovated by an abundance of lime or fresh mould. Hence new orchards planted in a good deep soil where none existed before, will produce far more abundant fruit, than if the trees had been planted in old orchard grounds; and the principle of change of crop extends to trees as well as to herbs.

Devonshire was formerly no doubt well wooded, and in some places there are still fine trees, but the progress of cultivation has greatly diminished the timber, and except in sheltered situations, trees do not thrive and acquire so great a size as they seem to have done when they sheltered one another. It has also probably been found out, that the return from a closely planted wood cut down at the end of thirty, forty, or fifty years, is greater than if the trees were allowed to increase for a century or two. Coppice wood however is plentiful, most of the steep sides of hills towards the banks of the rivers being covered with this growth, which adds considerably to the beauty of the valleys. The coppice wood is generally cut when twenty years old, some few poles being left till the next cutting. The best trees survive four or five cuttings; but unless they

be very fine and thriving, they are usually cut down at threescore years old. The coppice wood is used for fencing, hurdles, and hop poles, and what is unfit for this purpose is sold in faggots for fuel, if near any town, or converted into charcoal. The value of a coppice cut at twenty years old, and which has been protected from the depredations of cattle, may be from 15*l.* to 20*l.* per acre. Where a coppice is well managed, and the timber preserved, the ground may be made to produce an average rent of from 15*s.* to 20*s.* per acre.

In some parts there are extensive furze brakes, which being cut every five years for fuel, produce a very considerable return, varying according to situation from 7*l.* to 10*l.* per acre.

It is to be observed that coppice woods with a southern aspect will be two years in twenty more advanced than those facing the north. A sheltered situation will often make a still greater difference; besides the coppice in the latter situation is considerably more valuable when it is sold. The wood grown in Devonshire is chiefly oak, but beech, ash and elder are interspersed, according to the soil and situation. The sweet chesnut was probably a common tree formerly in sheltered situations in Devonshire, as the oldest buildings contain timbers of this tree. How it has been nearly extirpated it is difficult to say; but the climate of the vales seems peculiarly suited to this tree, so useful for its fruit as well as its timber. Since the late discovery of the quantity of sugar which can be extracted from the chesnut, this tree may again become an object of interest to those who form new plantations.

Trees planted on the summit of the hills in Devonshire, seldom succeed, owing to the violence of the winds; but on the slopes of the hills they thrive well, and as they ascend, they protect each other; and thus in time the tops may be covered. Where the Scotch fir and larch have been planted in sheltered situations, they thrive well.

On a general retrospect of the agriculture of Devonshire, it must be allowed to be good, and yet it is capable of much improvement. When the springs, which are abundant, shall have been collected in drains, and the water turned into channels where it may be rendered useful to turn mills or irrigate meadows, instead of injuring the arable fields; when the meadows shall have been improved by judicious cultivation, and when a better system of convertible husbandry, shall be more generally introduced; the soil and climate of Devonshire, will make it one of the first counties for producing every kind of animal and vegetable food, and the cultivation will extend to thousands of acres which now are looked upon as almost absolutely barren.

The principal fairs in this county are:—Ashburton, June 4; August 10; November 11. Axminster, April 25; Wednesday after June 24. Bampton, Wednesday before March 25; Whit Tuesday; last Thursday in October; last Wednesday in November. Barnstaple, September 19; second Friday in December. Broad Hembury, December 11. Collumpton, first Wednesday in May; first Wednesday in November. Crediton, May 11; August 21; September 21. Chagford, March 25; May 4; September 29; October 29. Culmstock, May 21; October 1. Dodbrook, Wednesday before Palm Sunday. Exeter, third Wednesday in February; third Wednesday in May; last Wednesday in July; second Wednesday in December. Hatherleigh, May 22; June 22; September 4; November 8. Hartland, Easter Wednesday; September 25. Holdsworthy, April 27; June 10; October 2. Honiton, first Wednesday after July 19. Kingsbridge, July 20. Modbury, May 4. Moreton Hampstead, June 4; July 18; November 30. Molton, (North) Tuesday after May 11, and November 12. Molton, (South) Saturday after February 13; Saturday after March 25; Saturday before August 1; Wednesday before June 22; Wednesday after August 26; Saturday before October 10; Saturday before December 12. Oakhampton, second Monday after March 11; May 14; first Wednesday after July 5; August 5. Plymouth, February 5; last Thursday in October. Plympton, February 25; April 5; August 12. Sampford Peverel, Monday before last Wednesday in April; first Thursday in July. Tawton, third Friday in April; November 3; December 11. Tavistock, January 17; May 6; October 10; December 11. Thorncombe, Easter Tuesday. Tiverton, second Tuesday after Trinity Sunday; September 29. Torrington, May 4; July 5; October 10. Totness, May 12; July 25; October 28. Uffculm, first Wednesday before Easter; August 12.

Divisions, Towns, &c.—In the Exon Domesday*, mention is made of at least thirty-eight hundreds into which Devonshire was then divided. In the hundred roll, a document of the time of Edward I., thirty-three hundreds (including that of Lovetot, incidentally mentioned as co-extensive with the manor of Fremington) are noticed. The present number is thirty-three. We give these three lists in a tabular form, placing in a line the name of the hundreds which are mentioned in more than one of the lists, and of those which, though mentioned by different names, are supposed nearly or quite to coincide.

Exon Domesday.	Hundred Roll.	Modern Name, Situation, Area, and Population in 1831.
Alleridge . . .	Harridge . . .	Hayridge, E. and Central, 44,890 acres, 13,444 inhabitants.
Axemeninstre . . .	Axeministre . . .	Axminster, E., 51,930 acres, 13,939 inh.
Axemuda . . .	Axemue . . .	Axemouth, united with Axminster; the united hundred was formerly called Axminster and Axmouth, now Axminster only.
Badentone . . .	Baunton . . .	Bampton, N.E., 29,430 acres, 7600 inh.
Brauntone . . .	Braunton . . .	Braunton, N., 68,830 acres, 21,974 inh.
Budeleie . . .	Buddele . . .	East Budleigh, S.E., 50,290 acres, 20,266 inh.
Cadelintone . . .	— . . .	West Budleigh, Central, 16,890 acres, 3047 inh.
Carsewille . . .	Haytorr . . .	Haytor, S.E., 61,340 acres, 24,143 inh.
Clridiatone . . .	Cridiaton . . .	Crediton, Central, 34,160 acres, 12,237 inh.
Clawetone . . .	— . . .	—
Clistone . . .	Cliston . . .	Cliston, Central, 19,260 acres, 3482 inh.
— . . .	Colrige . . .	Coleridge, S., 50,090 acres, 20,339 inh.
Culintone . . .	— . . .	Colyton, E., 27,410 acres, 7374 inh.
Dippeforde . . .	Stanburg . . .	Stanborough, S., 61,870 acres, 14,521 inh.
Esseministre . . .	Exminstre . . .	Exminster, S.E., 43,740 acres, 18,232 inh.
Framintone . . .	Fremington . . .	Fremington, N.W., 33,350 acres, 8844 inh.
Halbreton or Hasbertone . . .	Hanberton . . .	Halberton, N.E., 10,090 acres, 2866 inh.
Hamiok . . .	Hemyok . . .	Hemiock, or Hemyock, E., 26,440 acres, 5807 inh.
Hermetone . . .	Ermyntone . . .	Ermington, S., 51,610 acres, 10,524 inh.
Hertesbie . . .	— . . .	—
Hertilande . . .	Hertilande . . .	Hartland, W., 30,360 acres, 4646 inh.
Liftone . . .	Lifton . . .	Lifton, W., 136,350 acres, 13,447 inh. Lifton includes Dartmoor Forest, which contains 53,900 acres, and had in 1831 353 inh.
— . . .	Lovetot . . .	—
Mertone . . .	Schefbeare . . .	Shebbear, N.W., 79,200 acres, 20,159 inh.
Mollande . . .	— . . .	—
Offecolum . . .	— . . .	—
Otrie . . .	— . . .	Ottery, E., 9470 acres, 3849 inh.
Plintone . . .	Plympton . . .	Plympton, S., 32,230 acres, 9817 inh.
Rueberge . . .	Rouburg . . .	Roborough, S.W., 60,170 acres, 86,430 inh. (with Plymouth.)
Scirewelle . . .	Syrewell . . .	Sherwell, N., 45,790 acres, 4186 inh.
Sutmolton . . .	Sudmolton . . .	South Molton, N.E., 67,930 acres, 13,825 inh.
Sulfertone . . .	— . . .	—
Tainbruge . . .	Teynebrugg or Tingebrugg . . .	Teignbridge, S.E., 53,230 acres, 14,465 inh.
Taintone . . .	— . . .	—
Tautone . . .	Nortauton . . .	North Tawton, Central, including Winkley, 65,300 acres, 13,422 inh.
— . . .	Tavystoke . . .	Tavistock, S.W., 19,790 acres, 6954 inh.
Toritone . . .	Blaka Toriton . . .	Black Torrington, W., 141,600 acres, 19,492 inh.
Tulvertone, or Twertone . . .	— . . .	Tiverton, N.E., 23,960 acres, 10,519 inh.
Walchentone . . .	— . . .	—
Wenfort . . .	Womford or Wonford . . .	Wonford, Central and S.E., 98,770 acres, 55,661 inh. (with Exeter.)
Wetrigge, or Witrige . . .	Wyrugg, or Wytherugg . . .	Witheridge, Central and N.E., 84,680 acres, 9567 inh.
— . . .	Wynklegh . . .	Winkleigh, or Winkley, Central, included in the return for North Tawton.

Clawtone hundred, in the Exon Domesday, evidently took its name from the village of Clawton in Black Torrington hundred; Mollande from the village of Molland Botreaux in South Molton hundred; Offecolum from the town of Uffculme, or Ufeulm, in Bampton hundred; Sulfertone from the village of Silverton in Hayridge hundred; Taintone either from the village of Drew's Teignton in Wonford hundred, near the upper part of the Teign, and not far from the road from Exeter to Oakhampton, or more probably from King's Teignton in Teignbridge hundred

* The 'Exon Domesday' contains a description of the five western counties, Wilts, Dorset, Somerset, Devon, and Cornwall; and is supposed to contain an exact transcript of the returns made by the Conqueror's commissioners at the time of the general survey from which the great 'Domesday' itself was compiled. The original is preserved among the records belonging to the Dean and Chapter of Exeter.

and Bishop's Teignton in Exminster hundred, both near the mouth of the Teign and not far from each other; and Walchentone from Walkhampton in Roborough hundred. The situation of Lovetot hundred has been mentioned already.

The county is divided into two parts for the purpose of parliamentary representation: each division sends two members. The divisions comprehend respectively the following hundreds:

Northern Division.—Bampton, Black Torrington, Braunton, Crediton, Fremington, Halberton, Hartland, Hayridge, Hemiock, North Tawton, Shebbear, Sherwell, South Molton, Tiverton, Winkleigh, Witheridge, West Budleigh.

Southern Division.—Axminster, Cliston, Coleridge, Colyton, East Budleigh, Ermington, Exminster, Haytor, Lifton, Ottery, Plympton, Roborough, Stanborough, Tavistock, Teignbridge, Wonford (except what is included in the city of Exeter).

Devonshire contains forty market-towns. Of the most important we subjoin a list, adding the locality of each, and the population in 1831. For further information the reader is referred to their respective articles:

Ashburton, a parliamentary borough on a small feeder of the Dart, 4165; Axminster, on the Axe, 2719; Bampton, on the Bathern, or Batham, a feeder of the Ex, 1961; Barnstaple, a parliamentary borough on the Taw, 6840; Bideford, on the Torridge, 4846; Brixham, near Berry Head, the southern extremity of Tor Bay, 5015; Dartmouth, a parliamentary borough on the Dart, 4597; Devonport, formerly called Plymouth Dock, or colloquially Dock, on the æstuary of the Tamer, near Plymouth, a parliamentary borough, population given with Plymouth; Exeter, a city, and the county town, on the Ex, 28,201; Honiton, a parliamentary borough on the Otter, 3509; Plymouth, on Plymouth Sound, a parliamentary borough, and one of the great naval ports of England, pop. including Devonport and Stonehouse, 75,534; Sidmouth, on the English Channel, 3126; Stonehouse, between Plymouth and Devonport, included in the parliamentary borough of Devonport, population given with Plymouth. [DEVONPORT.] Tavistock, a parliamentary borough on the Tavy, 5602; Tiverton, on the Ex, a parliamentary borough, 9766; Totness, a parliamentary borough on the Dart, 3442.

Of the remaining towns we shall subjoin an account here, giving them in alphabetical order.

Appledore is a port and market-town on the western side of the river Torridge, just at its junction with the Taw; it is in the parish of Northam, and in the hundred of Shebbear, 204 miles west by south of London, through Barnstaple and Bideford. It is a small place, but has a considerable coasting trade. Risdon, who compiled his survey of Devon A.D. 1605-1630, says of Appledore that it is 'a place, since our fathers' age, meanly inhabited, but at present mustereth many mansions, and may for multitude compare with some towns.' Appledore has two weekly provision markets, on Wednesday and Saturday, for the convenience of shipping. There is a chapel in the town kept in repair by the church of Windsor, but it has not been used as a place of public worship within memory: the church is at the village of Northam, above a mile from the town. The living of Northam is a vicarage, of the yearly value of 125*l.*, with a glebe-house, in the gift of the dean and chapter of Windsor. The parish contains places of worship for Independents, Baptists, and Wesleyan Methodists. The population of the parish in 1831 was 2727; that of the town of Appledore was not distinguished. The education returns from this parish in 1833 contain six infant schools with about 90 scholars; seven day-schools (one a national school of 50 boys and 30 girls, supported by an endowment and by subscription), containing in all 274 scholars; and three Sunday-schools with above 200 scholars. A parochial lending library is connected with the national school, and a lending library with one of the Sunday schools.

On the coast, near Appledore, is a sandy tract of about 800 acres, called 'Northam Burrows,' adjoining to which is a high bank of pebbles, about a mile long, resembling the Chesil-bank, near Weymouth. Kinwith, or Kenwith Castle, in besieging which Ubbo or Hubba the Dane was killed, A.D. 878, was near Appledore. Henni Borough, or Henni Castle, a small fortified spot not far from Bideford, has been supposed to be the site of this castle.

South Brent is a small town in the hundred of Stan-

borough, on the road from Exeter to Plymouth, and on the river Avon or Aune, twenty-six or twenty-seven miles from Exeter, and sixteen or seventeen from Plymouth. The population of the parish, which is very large (10,180 acres) was, in 1831, 1248, chiefly agricultural. The market is on Friday; and there are two fairs in the year. The living is a vicarage, endowed with the great tithes, and worth 122*l.* a year, with a glebe house. The education returns for 1833 give for this parish four day-schools with about 200 children (one of these schools, containing 50 children, is endowed), and two Sunday-schools containing 100 scholars.

Chagford is in the hundred of Wonford, near the right bank of the Teign, and not far from the border of Dartmoor Forest, three and a half miles west by north of Moreton Hampstead, and fifteen or sixteen west by south of Exeter. This small town lies in a picturesque situation at the foot of some rugged and lofty hills. There is a bridge of three arches over the Teign, half a mile above the town: the church is an antient structure, and there are remains of antient chapels at Great Week and Teigncombe in the parish. The parish is large (8710 acres) and contains several hamlets: the population in 1831 was 1868, about half of whom were engaged in agriculture, and a few in the manufacture of woollens. The market is on Saturday, and there are four fairs in the year. The living is a rectory, of the yearly value of 442*l.*, with a glebe house. The number of schools in the parish by the returns of 1833 was as follows: five day-schools (one partly supported by an endowment), with 190 children, and three Sunday-schools with 210 scholars. There are places of worship for Wesleyan Methodists and Calvinistic Baptists. Chagford is one of the Stannary towns. In 1643, during the great civil war, there was an action at Chagford between the Parliamentarians and the Royalists, in which the Royalists were victorious. In the latter part of the seventeenth century the town was destroyed by fire.

Chudleigh is in the hundred of Exminster, a short distance from the left bank of the Teign, and on the road from Exeter to Plymouth, between nine and ten miles from Exeter. The town, which is situated in a delightful country, chiefly consists of one long street, having the church, a small building, in which are some monuments of the Courtenay family, at its south-western extremity. There is a bridge over the Teign, nearly a mile from the town. The population of the parish, which comprehends 6230 acres, was, in 1831, 2278, of whom about a third were engaged in agriculture, and a few in manufactures, probably of woollens. The woollen manufacture was once pursued more extensively. The neighbourhood of Chudleigh is very productive in cider. There is a market on Saturday, and three fairs in the year, chiefly for cattle. There is a Dissenting meeting-house in the town. The living is a vicarage, of the yearly value of 505*l.*, with a glebe house, in the gift of the parishioners, who purchased the advowson. There were in 1833 four infant schools with 91 children; six day-schools (two of them, containing 60 to 80 children, supported partly or wholly by endowment; and one, for the children of Catholic parents, partly supported by charitable contributions), containing altogether 140 to 160 children; and one Sunday-school with 93 scholars and a library attached. One of the endowed schools is a grammar-school.

The bishops of Exeter had formerly a palace at Chudleigh, of which there are some remains a quarter of a mile from the town: the manor formed part of the possessions of the see. Ugbrooke, a mile south-east of the town, now the residence of Lord Clifford, was formerly the residence of the precentor of Exeter cathedral. The park, with the adjacent pleasure grounds and plantations, occupies a space several miles in circumference; it is richly wooded, and is adorned with a large piece of water and a cascade; the house contains some good paintings by the antient masters. About half a mile from the town is 'Chudleigh Rock,' a limestone cliff celebrated for its picturesque appearance. Midway down the cliff is a cavern, the entrance to which is by a natural arch, twelve feet wide and ten feet high; according to tradition, a dog put into this cavern, which soon becomes too contracted for men to trace it, came out at a place three miles distant. Local superstition has peopled this cavern with Pixies, a minute variety of the fairy race. The limestone quarried is here considered to be of superior quality. Many persons are employed in these works.

In May, 1808, a dreadful fire broke out at Chudleigh,

by which 166 houses were destroyed: the damage was estimated at 60,000*l.*, and the sum of 21,000*l.* was promptly gathered by subscription for the relief of the poorer sufferers.

Chulmleigh, Chumleigh, or Chimleigh, is in the hundred of Witheridge, on the north bank of the Little Dart, just above its junction with the Taw. It is on the road from Exeter to Barnstaple, about twenty-one or twenty-two miles north-west from Exeter. It is a small town. The parish contains 8650 acres, but had in 1831 not more than 335 houses (including 1 building and 30 uninhabited) and 1573 inhabitants, more than half of them engaged in agriculture. The church, dedicated to St. Mary Magdalen, was much damaged by lightning in 1797. It contains some antient screen work. There were, in 1772, chapels at Ladywell and Cadbury, both desecrated, and some remains of chapels at Coleton, or Colleton, and Stone, all in this parish. There is one Dissenting place of worship, if not two, in the town. The manor of Chulmleigh once belonged to the Courtenays, earls of Devon, who had a castle here, of which there are no remains. In 1803 a destructive fire broke out in the town, and destroyed ninety-five houses and uninsured property to the value of 11,000*l.* The market is on Friday, but as a corn-market is almost disused; there are three fairs in the year.

The church was formerly collegiate, and has five prebends, which are not necessarily united with the rectory, though of late years they have been held by the rector. The present value of the rectory (we presume without the prebends) is 415*l.* a year. The education returns of 1833 assign to the parish five day-schools with 210 scholars; one day and Sunday-school with 20 day scholars and 13 additional on Sundays, who attend the Established Church; and two Sunday-schools, one supported by Churchmen and the other by Independents, with 120 children in each. Two of the day-schools are partially endowed, another is supported by the Independents.

Collumpton, Columpton, or Columpton, otherwise Cul-lompton or Cullumpton, is in Hayridge hundred, on the right or west bank of the Culm, a tributary of the Ex, and on the road from Taunton to Exeter, twelve miles north-east of Exeter. Collumpton is a town of tolerable size, having its main street along the Exeter and Taunton road, nearly a mile in length; other shorter streets branch off from this. The streets are ill-paved; but the houses are tolerably well built, some thatched and some covered with slate.

The whole number of inhabited houses in the parish, which comprehends 5790 acres, was, in 1831, 787: the number of inhabitants was 3813. About one-third of the adult males were engaged in agriculture, and about one-fourth in manufactures. There are several bridges over the Culm or the brooks which flow into it. The church, which is dedicated to the Virgin Mary, is very antient and handsome; it is in the perpendicular English style, and has an elegantly carved and gilt roof. A Gothic chapel was added by John Lane, a clothier of the town, who died in the reign of Henry VIII., and is buried in the chapel: it is a specimen of the gorgeous richness of that time. The tower of the church is 100 feet high. There are the remains of a chapel at Langford. There are meeting-houses for Independents, Baptists, Quakers, Wesleyan and Bryanite Methodists, and Presbyterians who have embraced Unitarianism. The principal manufacture is of woollen goods, as serges, kerseymeres, and a few broadcloths. The market is on Saturday for butchers' meat and other provisions, and occasionally for corn: there are two fairs in the year for cattle, cloth, &c. Petty sessions are held here: the town and the adjoining parish of Kentisbere are governed by a high constable chosen yearly, and alternately by Collumpton and Kentisbere.

The living is a vicarage of the yearly value of 351*l.* with a glebe-house, in the gift of R. B. de Beauvoir, Esq.: the church was formerly collegiate. In 1833 there were, at Collumpton, a national school, supported by subscriptions, with 221 scholars (116 boys and 105 girls), and seven other day schools, with 99 boys and 96 girls; and five Sunday-schools, with 548 scholars: to one of the Sunday-schools a lending library is attached.

Colyton or Culliton is in the hundred of Colyton, and on the little river Coly, a feeder of the Axe, about twenty-two miles east of Exeter. The town is pleasantly situated, but small; the houses, many of which are antient, are princi-

pally built of flint and covered with thatch. In 1831, there were in the parish, which comprises 5430 acres, 436 inhabited houses and 2182 inhabitants: about two-fifths of the adult males were engaged in agriculture. The church is a fine cruciform structure, in the perpendicular English style: it has been enlarged by subscription in the course of the present century. There is a fine stone screen across the south transept, and an altar tomb of a young lady of the Courtenay family, granddaughter of Edward IV. An adjoining chapel is the burial-place of the family of De la Pole. The upper part of the tower of the church is octagonal. The vicarage house is an antient structure. There were formerly chapels at Colcombe, Colyford, Whitford, Gatcombe, and Leigh, in this parish. There are some valuable lands at Colyton, left for charitable purposes, from which a school for 20 or 25 boys is supported. There are meeting-houses for Independents and Unitarian Presbyterians. The markets are on Thursday and Saturday, and there are two fairs in the year for cattle.

The living of Colyton is a vicarage with the chapelries of Monkton and Shute annexed, worth 403*l.* per annum with a glebe-house, in the gift of the dean and chapter of Exeter, in whose peculiar jurisdiction it is. According to the return for 1833, there were in Colyton parish eight day schools (including the endowed school), with 198 children; and two Sunday-schools (one partly endowed), with 235 scholars.

In the parish of Colyton is Colyford, a considerable village, which is incorporated and governed by a mayor, who receives the profit arising from the tolls of a large cattle fair held annually. Near the town also are Colcombe castle, once the seat of the Courtenays, earls of Devonshire, and of the De la Poles; and Yarbury, the seat of a branch of the Drakes: both are now converted into farm-houses.

Crediton, antiently written Chridiatone, Cridiaton, Crideton, and Kirton, which last is still the colloquial designation, is in the hundred of Crediton, near the junction of the brook Yeo with the river Creedy, a feeder of the Ex, seven or eight miles north-west of Exeter: the Creedy flows a short distance from the town to the east, the Yeo a short distance to the south. The area of the parish is 11,440 acres: it is divided into ten tythings, containing in all, in 1831, a population of 5922. The town is divided into East town and West town: it is irregularly built; the principal street runs nearly east and west, between two hills, of which that on the south rises with a quick ascent and overtops the houses. The church is a handsome cruciform structure in the later perpendicular style of architecture; it stands in the middle of the town and was probably erected about the close of the fifteenth century. The interior is very neat: the tower rises from the intersection of the nave and aisles, and is supported by four pillars of uncommon magnitude. This church contains a parochial library once consisting of 1000 volumes, but many have been lost, and the rest are becoming a prey to worms and spiders. (*Beauties of England and Wales.*) There is an antient decayed chapel at the west end of the town, formerly belonging to the hospital of St. Lawrence; and the walls of a chapel at Yew or Yeo, in the parish. The serge manufacture was established in Crediton from the first introduction of it into the county, and was formerly carried on with considerable activity. Vast quantities of wool and yarn were sold weekly in the market-place; but this branch of industry has declined in Crediton, as it has elsewhere in Devonshire, and the returns of 1831 gave only 5 adult males out of 1336 as engaged in manufactures of any kind: 468 adult males were at the same time engaged in agriculture as occupiers of land or labourers, and 566 in trade or handicrafts. The market, which is on Saturday for corn and provisions, is considerable, but not equal to what it was formerly: the market which precedes the last Wednesday in April is one of the largest marts for bullocks in the west of England. There are three cattle fairs in the year. There are congregations of Presbyterians (who have, like many of the English Presbyterians, embraced Unitarian sentiments), Independents, Baptists, and Methodists. There are two sets of almshouses, each for four poor persons.

There is said to have been a collegiate church at Crediton early in the time of the Saxons, which church, upon the division of the diocese of Sherborne in the reign of Edward the Elder, was made the cathedral of the bishops of Devonshire, about A.D. 905 or 910: about A.D. 1040, the

diocese of Crediton was enlarged by the addition of that of St. German's, which included Cornwall; but in A.D. 1050 the see was removed to Exeter. The palace at Crediton continued to be the occasional residence of the bishops, and the manor and hundred of Crediton continued to belong to them till the reign of Henry VIII., when the bishop (Veysey) reluctantly surrendered them to the crown. The site of the old church or cathedral, dedicated to St. Gregory, is now occupied by a range of houses by the side of the present churchyard. Although the see was removed to Exeter, the church retained the chapter, which consisted of eighteen canons or prebendaries, of whom three bore the titles of precentor, treasurer, and dean, and eighteen vicars. The chapter was dissolved in the reign of Edward VI.: its yearly revenue at the dissolution amounted to 332*l.* 17*s.* 5*d.* The small tithes, and subsequently the great tithes, of Crediton, Sandford, and Exminster, were vested in a corporation of twelve governors, nine from Crediton and three from Sandford. The governors appoint the vicar of Crediton, who has a yearly stipend of 400*l.* with a parsonage house: there is an assistant minister who has 200*l.* a year.

Crediton sent representatives to the parliament held at Carlisle in the time of Edward I. The town is governed by a portreeve: petty sessions are held here.

There were, in 1833, in Crediton parish, one infant school, partly supported by subscription, and containing 90 children; an endowed grammar school, containing 20 boys; a Lancasterian school, with 200 children, partly endowed and partly supported by subscriptions and collections; an endowed school for 15 boys; and nine other schools, containing 285 children; one day and boarding school, with 60 scholars; and six Sunday-schools, with 352 children.

Crediton was occupied by the revolvers who rose in the west of England A.D. 1549, on account of the Reformation, but they were driven out by Sir Peter and Sir Gawen Carew. The town was repeatedly occupied by the contending parties in the civil war of Charles I. In A.D. 1743 a dreadful fire broke out in the western town, which occasioned the destruction of 460 houses; the damage was estimated at 40,000*l.*, and sixteen lives were lost. In 1769 a second fire consumed many of the houses rebuilt after the former fire, together with the market-house and shambles.

Culmstock or Columbstock is on the border of Somersetshire, in the hundred of Hemyock, on the upper part of the river Culm, nineteen or twenty miles north-east of Exeter. The parish comprises 4530 acres or seven square miles, and includes several villages and hamlets besides the town: it had, in 1831, 312 inhabited houses and 1519 inhabitants: of the adult males nearly one half were engaged in agriculture, and nearly one-seventh in manufactures. There is a market-house, 'built,' say Messrs. Lysons (*Magna Britannia*, vol. vi., p. 151, published 1822), 'not many years ago by the dean and chapter of Exeter.' The market, now much declined, is held on Friday for butchers' meat. There are two fairs in the year, at one of which cloth is sometimes sold; but the clothing trade, which once flourished in this place, has much declined. The church, dedicated to All Saints, is in the centre of the town; it contains a fine stone screen, with a rich doorway, canopied with foliage. There are meeting-houses for Quakers and Wesleyan Methodists; and one for Calvinistic Baptists at the village of Prescott, in the parish. The living is a vicarage, in the gift of the dean and chapter of Exeter, in whose peculiar jurisdiction it is: its annual value is 250*l.* with a glebe-house. There were in the parish, in 1833, two day-schools (one of them partly supported by contribution), with 144 children; and three Sunday-schools, with nearly 300 children.

Hatherleigh is in the hundred of Black Torrington, on the east or right bank of a stream which flows into the Torridge a short distance above the junction of the Oke-mot: Hatherleigh is twenty-eight miles west-north-west of Exeter. The parish comprises 6500 acres, and had in 1831, 290 inhabited houses and a population of 1606. Of the adult males nearly two-thirds were engaged in agriculture, and a very few in the manufacture probably of woollens. The town is very irregularly laid out, and the houses, which are principally built of red clay, and are thatched, have a very mean appearance. The market is on Tuesday and Saturday, and there are four cattle fairs in the year and a large cattle market on the Friday nearest the 21st of March. The town is governed by a portreeve, two constables, and other officers annually chosen at the court held

by the lord of the manor. Petty sessions are held here. The living is a vicarage, of the annual value of 202*l.* with a glebe-house. There were in the parish in 1833, five day-schools (one of them supported partly by endowment and subscription) containing 150 to 155 children, and one Sunday-school with 160 scholars: a lending-library is attached to the Sunday-school.

The manor of Hatherleigh formerly belonged to the abbey of Tavistock; one of the abbots gave a large plot of common land for the advantage of the townsmen.

Holsworthy is in the hundred of Black Torrington, not far from the east or left bank of a small stream that flows southward into the Tamer: it is forty-one or forty-two miles west by north of Exeter. The parish, which comprises 8870 acres, includes besides the town, four villages, if not more: the population in 1831 was 1628; not quite half of the adult males were engaged in agriculture. The Bude and Holsworthy canal, which unites with the Bude and Launceston canal, passes near the town. The market, which was held formerly on Saturday, has lately been changed to Wednesday; there is a great market on the second Wednesday in February, and there are three fairs in the year; one of them (in October) is a great fair for cattle and all sorts of commodities. The parish church is antient: it has some Norman piers and a plain Norman door, and some portions of later date. There were formerly chapels at Chelsworthy and Thorne in the parish. There are places of worship for Independents and Wesleyan Methodists. The petty sessions for the division are held at Holsworthy. The living is a rectory of the yearly value of 478*l.*, with a glebe-house. In 1833 there were in the parish six day-schools (one of them partly supported by subscription) with 222 children, and three Sunday-schools with about 250 children.

Ilfracombe is in the hundred of Braunton, on the coast of the Bristol channel, ten miles north of Barnstaple, and forty-seven or forty-eight north-west from Exeter. The parish has an area of 3620 acres, and had, in 1831, a population of 3201: of the adult males more than one-fifth were engaged in agriculture, and about the same number in retail trade and handicraft: there is a considerable coasting trade and herring fishery. The town consists of one main street extending north-east and south-west along the sea-coast, and reaching at the north-east end to the harbour, which is formed by an inlet or cove of the Bristol channel, very commodious and safe, affording anchorage to vessels of 230 tons, and rendered additionally secure by a pier 850 feet in length. The harbour being accessible to vessels which cannot make Barnstaple or Bideford, has caused much of the port business of Barnstaple to be transferred hither: there are a battery and lighthouse at the entrance of the harbour. Oats are the chief article of export. The houses are tolerably well built; a number, intended for the reception of visitors, range along the harbour. The shore is convenient for bathing, and there are warm baths for invalids. The town is considered an agreeable summer residence, and is much resorted to. There is a market on Saturdays well supplied with fish, and two cattle fairs in the year. The church is a large building at the south-west end of the town; it contains a monument, erected at the national expense, to the memory of Captain Richard Bowen, R.N., who fell in the unsuccessful attack made by Nelson on Teneriffe, July, 1797. There are meeting-houses in the parish for Wesleyans and Independents. The town is governed by a portreeve.

The living of Ilfracombe is a vicarage of the yearly value of 150*l.* with a glebe-house; the rectorial tithes are in the hands of one of the prebendaries of Salisbury cathedral who is patron of the vicarage. There were at Ilfracombe in 1833 one national school with about 130 children, supported partly by an endowment and subscriptions, and partly by a small weekly payment from the children: nineteen day-schools with 341 children (one of these schools with 18 children is supported by a small endowment and by subscription), and two Sunday-schools with 356 children.

Kingsbridge is in the hundred of Stanborough, in the southern part of the county, a short distance north-west of Start Point, at the head of a considerable æstuary into which a number of small streams flow: it is thirty-five miles south-south-west of Exeter. The town may be considered as composed of Kingsbridge and Dodbroke, or Dodbrook, which is in Coleridge hundred, and is separated from Kingsbridge only by a rivulet. The area and population of these parishes in 1831, were, Kingsbridge, 150 acres, 1586 inhabitants;

Dodbroke, 420 acres, 1038 inhabitants; total 570 acres, 2624 inhabitants. The number of inhabited houses in the two parishes was in 1831, 378. Of the adult male population scarcely more than one-tenth was engaged in agriculture, and scarcely any in manufacture: the manufacture of woollen cloths and serges formerly carried on with considerable activity having become nearly or quite extinct. Ships of burden can come up to the town at high water, and there are two quays, one in Dodbroke, and the other in the parish of West Alvington, or Allington, adjacent to Kingsbridge. Cider, corn, malt, and slate are exported; the chief imports are sea-borne coals. The market is on Wednesday, for corn, butchers' meat, and provisions: the corn-market is one of the largest in Devonshire. There is one fair in the year. Kingsbridge consists mainly of one street on the Modbury and Plymouth road; Dodbroke, of one on the Exeter road: these streets unite at the lower end of the town near the haven. The church of Dodbroke, dedicated to St. Thomas-à-Becket, has an early stone font, and some portions of good screen work. There are meeting-houses for Independents, Baptists, Quakers, and Wesleyan Methodists. The living of Kingsbridge is a vicarage united with that of Churchstow, or Churstow, an adjacent parish to the north-west; their joint yearly value is 118*l.*; they are in the gift of the crown. The living of Dodbroke is a rectory of the yearly value of 183*l.*, with a glebe-house. There were in Dodbroke in 1833, 6 day-schools with 130 children, all very young; and in Kingsbridge, 1 infant school with 14 children, and 7 other day-schools, 6 of them containing 150 children of both sexes; the seventh is a grammar-school endowed for the instruction of at least 15 boys, with exhibitions for three or four scholars to the universities: the number of scholars actually taught is not stated in the return. There were in Kingsbridge also 4 Sunday-schools with 97 scholars.

Modbury is in the hundred of Ermington, on a rivulet whose waters flow into the Erme: thirty-five miles south-west of Exeter. The parish comprehends an area of 5910 acres, and had, in 1831, 364 inhabited houses, with a population of 2116 persons. Besides the town the parish comprehends the villages of Brownston, Leigh, Caton, Penquit, part of Ludbrook, and others. Nearly half of the adult males are engaged in agriculture, scarcely any in manufacture. The town consists of an irregular assemblage of streets. The church is spacious and handsome: the tower is 134 feet high, built soon after the church in 1621. There are meeting-houses for Baptists, Independents, Quakers, and Methodists. There are some ruins of the antient mansion of the Champenounes, who held the manor of Modbury, and lived here in great splendour: a large deer-park which was at a small distance from the mansion, is now converted into a farm, which retains the name of Modbury Park. Modbury is a borough, though without a charter of incorporation: it sent representatives to parliament in the reign of Edward I., but it is said soon to have got excused on the ground of the expense: whether this was the cause is, however, doubted by Messrs. Lysons. Modbury is now governed by a portreeve (usually styled mayor) two constables, and several other officers, chosen at a court-leet. Until the beginning of the eighteenth century the borough court took cognizance of debts under forty shillings. There was an alien priory of Benedictines here as early as the reign of Stephen, but it was suppressed at the dissolution of alien priories, and its revenues, valued at 70*l.* per annum, were given by Henry VI. to Eton College. The market is on Thursday, for corn, butchers' meat, and other provisions: there is a great market for cattle on the second Tuesday in every month, and a great fair for cattle, cloth, and other merchandise, in the month of May. The living of Modbury is a vicarage of the annual value of 302*l.*, with a glebe-house, in the gift of Eton College. There were at Modbury in 1833, two infant schools with 76 children, and a Lancasterian school with 70 boys, all partly supported by charitable contributions; four other day-schools with 116 children, and three Sunday-schools with 287 children. A lending-library is attached to one of the Sunday-schools.

South Molton is a market-town and municipal borough in the hundred of South Molton, twenty-seven or twenty-eight miles north-west of Exeter, on the right or west bank of the river Mole. The limits of the borough are the same as those of the parish, and comprehend an area of 6160 acres, with a population, in 1831, of 3826: of the

adult males about three-eighths were engaged in agriculture. The town is well situated for business at the convergence of several principal roads, viz.: one from Exeter by Crediton, one from Tiverton, one from Barnstaple, one from Torrington, and one from Chulmleigh: it consists of a spacious market-place and several streets, well paved, with flagged foot-ways, and lighted; the public walks are kept remarkably clean. The guildhall is a convenient building, and the borough gaol, built a few years since, contains six cells (two of them strong cells,) two large day-rooms and a good yard. The church, which is adjacent to the market-place, is a handsome building in the perpendicular style of architecture: it has a rich stone pulpit adorned with statues and a profusion of varied carved foliage. There are meeting-houses for Independents and Wesleyans. At Honiton, two miles south-west of the town, is an episcopal chapel, built on the site of a more antient one, and handsomely decorated, and endowed by the Rev. Lewis Southcomb, A.D. 1730; over the altar-piece is a picture of our Saviour baptized by John the Baptist.

The woollen manufacture is carried on at South Molton to some extent; nearly 70 adult males are engaged in it: serges, shalloons, and felts were formerly made, and (in 1822) coarse woollens for Spain and the East Indies; the lace manufacture has recently been introduced. The markets are on Tuesday and Thursday for butchers' meat, and on Saturday for corn and provisions generally: the Saturday market is considerable, and there are great markets on the Saturday after February 13 and March 25, and before April 23, August 1, October 10, and December 12. There are two fairs in the year for horses and cattle.

By the Municipal Reform Act the town has a mayor, four aldermen, and twelve councillors. The sessions of the peace are held quarterly, the petty sessions every three weeks, or oftener if required, and the court of record every three weeks.

The living of South Molton is a perpetual curacy in the gift of the dean and chapter of Windsor, who are impropiators of the great tithes which they lease to the corporation; the annual value of the curacy is 157*l*. The number of schools in the parish in 1833 was as follows: eleven infant (or dame) schools, with about 200 children; seven day, or day and boarding-schools, with above 350 children; and three Sunday-schools, with 640 children. Of the day-schools one is an endowed grammar-school; one (the Blue-coat school, in which most of the children are clothed), is supported by an endowment and contributions; and a third is supported by contributions.

Moreton Hampstead is in Teignbridge hundred, near the eastern border of Dartmoor Forest, and near the Wadley brook, which flows into the Bovey river, and so into the Teign, twelve miles west by south of Exeter, on one of the roads from that place to Tavistock and Plymouth. The area of the parish is 7370 acres, and it contained in 1831, 383 inhabited houses, and a population of 1864. The town is romantically situated on a gentle eminence bounded on almost every side by high hills. The principal street runs for about half a mile along the Exeter and Plymouth road. There are meeting-houses for Unitarians, Independents, Baptists, and Methodists. Of the adult male population above half are engaged in agriculture: there are no manufactures carried on: that of woollen yarn and serge has become extinct. The market is on Saturday for corn and provisions; the market next before Whitsuntide is a great cattle market: there are two cattle fairs in the year. The town is governed by a portreeve, and other officers chosen annually at the court of the lord of the manor. The townspeople are distinguished by singularity of dialect and manners, owing probably to their secluded situation on the border of Dartmoor. The living is a rectory in the gift of the earl of Devon: annual value 401*l*., with a glebe-house. There were in the parish in 1833, eight infant schools, with 70 scholars; one day-school, with 33 boys and 6 girls, partly supported by an endowment and an allowance from the parish; six other day-schools, with 69 boys and 42 girls; and three Sunday-schools, with 82 children; one of the Sunday-schools has a lending-library attached to it.

Newton Abbot is in the parish of Woolborough, or Woolborough, in the hundred of Haytor; and Newton Bushel, which is adjacent to Newton Abbot, being separated from it only by a narrow brook which flows into the Teign, is in High Week parish, and in Teignbridge hundred: the two may be considered as forming one town a short distance from the south or right bank of the Teign, fifteen miles

south by west of Exeter. The area, population, &c., of the parishes by the census of 1831 were as follows:—

	Acres.	Inhabited houses.	Inhabitants
High Week . . .	2140	216	1109
Woolborough . . .	970	442	2194
Total . . .	3110	658	3303

Of the adult male population, amounting to 734 persons, 110 were engaged in agriculture and only 3 in manufactures. There is a market on Wednesday held at Newton Abbot; that on the last Wednesday in February is a great cattle market: there are three cattle fairs in Newton Abbot. The principal street of the town runs north-west and south-east for above half a mile: another principal street runs into this from the south-west, and there are some smaller ones: the houses are indifferently built, and the streets ill paved: the market-place and shambles in the principal street obstruct the thoroughfare. The parish churches are at some distance from the town: there is a chapel of ease at Newton Bushel, the minister of which is appointed by the incumbent of High Weeks, and another chapel in Newton Abbot, served by the minister of Woolborough. There are meeting-houses for Independents and Calvinistic Baptists. There is an alms-house in the parish of Woolborough for two clergymen's widows, originally for four. The living of High Week is a curacy united with the vicarage of King's Teignton; the value of the joint livings is 396*l*., with a glebe-house, in the gift of the prebend of Teignton Regis, or King's Teignton, in Salisbury cathedral. The living of Woolborough is a donative united with the curacy of Newton Abbot, of the annual value of 235*l*., in the gift of the earl of Devon. In 1833 there were in High Week and Woolborough parishes, one national school, containing 82 boys and 64 girls, who were taught daily, and 10 boys and 12 girls additional on Sunday; one endowed day-school for 100 children of both sexes; two boarding and day-schools, with 63 scholars, eight day-schools with above 200 children of both sexes, and one Sunday-school of 33 children.

Oakhampton, or Okehampton, is in Lifton hundred, on the northern border of Dartmoor, at the junction of the East and West Okement rivers, twenty-two miles west of Exeter, on the road to Launceston. The parish comprehends an area of 12,570 acres, and includes, beside the town of Oakhampton, the villages of Chissacot and Meldon, and the hamlet of Kigbear, which extends into Black Torrington hundred. The number of inhabited houses in 1833 was 393, of inhabitants 2055: of the adult males about half were engaged in agriculture; none in manufactures. The town lies in a valley, and is surrounded by rich meadows and wooded acclivities. The town is irregularly laid out. There is an old chapel in the market-place, dedicated to St. James, originally founded as a chantry, which belongs to the corporation; divine service is occasionally performed in it. The church is on an eminence some distance west of the town. There are in the parish places of worship for Independents and Wesleyan Methodists. Oakhampton Castle, formerly in the possession of the Courtenays, was on a hill within a mile south-west of the town. It was dismantled by order of Henry VIII., and is now a mere ruin; the extent of the area occupied by it, and the solidity of the walls, show it to have been a fortress of importance. Oakhampton is a place of little trade: the market is on Saturday: that next before Christmas is a great cattle market. There are seven fairs in the year; one of them, a holiday fair, called 'Giglet Fair,' is held on the Saturday next after Christmas Day. Oakhampton is a municipal, and was, up to the passing of the Reform Act, a parliamentary borough. The bounds of the borough included the whole parish. It sent members to parliament in the reigns of Edward I. and Edward II., but the privilege was lost or disused until the time of Charles I.; the right of election was in the freeholders or the freemen by servitude and their eldest sons: it was disfranchised by the Reform Act. The municipal corporation consisted of a mayor, eight principal and eight assistant burgesses, with other officers. When the commissioners for inquiring into the state of the municipal corporations visited Oakhampton, the borough court of record had gone quite into disuse, the borough sessions nearly so, and the gaol was in a most wretched state: the chaplaincy of St. James's chapel had been long vacant, and the grammar-school given up.

The living of Oakhampton is a vicarage, of the yearly value of 480*l.*, with a glebe house. There were in the parish, in 1833, thirteen day-schools with 348 children, and three Sunday-schools with 315 children. Four of the day-schools, containing 128 children, are supported by subscription: one of the Sunday-schools has a lending library attached.

Ottery St. Mary is in the hundred of Ottery, and on the east or left bank of the river Otter, about eleven miles from Exeter. The hundred of Ottery contains only this parish, which has an area of 9470 acres; the population in 1831 was 3849: of the adult males above half were engaged in agriculture, and only one person in manufacture. The town is irregularly laid out, but in a pleasant situation. The church, formerly collegiate, is large and in the form of a cross: it resembles Exeter cathedral in having two towers for transepts. The architecture is chiefly in the early English style, of a character rather different from what is common, and with various alterations of a later date: the northern tower is crowned by a low spire. There is a Lady chapel. There are several monuments in the church of some antiquity, especially an altar tomb with the effigy of an armed knight and a rich monumental arch over it. There were formerly chapels at Ottery dedicated to St. Saviour and St. Budeaux, and also chapels of which there are some remains at Holcome and Knighteston, in the parish. There is a place of worship for Independents. The remains of an ancient mansion, once inhabited by Sir Walter Raleigh, are said (*Beaut. of Eng. and Wales*, 1809) to be yet existing; and there are some antient collegiate houses just outside the churchyard. The serge manufacture, formerly flourishing, has declined. The market is on Tuesday for butchers' meat and provisions, and there are three fairs in the year.

The living of Ottery is a vicarage in the gift of the lord chancellor, of the yearly value of 112*l.* with a glebe house. There were, in 1833, one infant-school with 40 children, principally supported by private charity: nine day or boarding and day-schools with 421 children; two day and Sunday-schools, with about 60 children, supported by private charity; and three Sunday-schools, with 257 children. Of the day or boarding and day-schools one is an endowed grammar-school, with hardly any boys on the foundation.

Plympton St. Maurice, commonly called Plympton Maurice, or Plympton Earl, is in the hundred of Plympton, not far from the south bank of the Tory brook, which flows into the Plym, and is on the road from Modbury to Plymouth, about thirty-nine miles south-west of Exeter. The parish contains only 170 acres: it had, in 1831, 123 inhabited houses, and a population of 804 persons. It was, up to the passing of the Reform Bill, a parliamentary borough, and has still a municipal corporation: the borough limits comprehend part of the adjacent parishes of Plympton St. Mary, and Brixton, and some extra-parochial ground. It is one of the stannary towns. There was formerly a castle here, belonging to the family of De Redvers, or Rivers, who held the earldom of Devonshire before the Courtenays. This castle was on the north side of the town; there are only some scanty remains of the walls of the keep, but the earth-works show it to have been a place of great strength. The town has two principal streets: the town-hall contains a portrait of Sir Joshua Reynolds, who was a native of the place, painted by himself. There is an Independent meeting-house. The market is on Friday for corn and provisions, and there are five cattle fairs in the year. The borough revenue has been insufficient to meet the expenditure; and as the supply afforded to the corporation funds by the patron of the borough has been withdrawn since the passing of the Reform Act, it is probable the corporation will fall into desuetude. The living of Plympton Earl is a perpetual curacy, of the yearly value of 100*l.*, in the gift of the dean and chapter of Windsor. The grammar-school, though endowed with estates producing upwards of 200*l.* a year, has been useless for twenty years or more, the office of master having been converted into a complete sinecure. There were, in 1833, six day-schools with 111 children, one boarding school with 17 girls, and one Sunday-school with 50 children.

Teignmouth is in the hundred of Exminster, at the mouth of the river Teign, on the north side of the river, about sixteen miles south of Exeter. It consists of East Teignmouth and West Teignmouth, which are separated by a small brook. The area, population, &c. of their respective parishes, according to the returns of 1831, were as follows:—

	Acres.	Inhabited houses.	Population.
East Teignmouth	700	315	1810
West Teignmouth	580	523	2878
Total	1280	838	4688

There are no manufactures carried on, and the proportion of persons engaged in agriculture is very small. Teignmouth is much frequented as a bathing-place, and has every accommodation for invalids. The trade too is considerable: the inhabitants are much engaged in the Newfoundland fishery. There are considerable exports of granite (for the conveyance of which from the Haytor quarries a railroad has been constructed), pipe-clay, potters' clay, manganese, timber, bark, and cider: the imports are of culm, coal, deals, iron, &c. There is a considerable fishery for soles, whiting, turbot, mackerel, and pilchards, on the coast, and for salmon in the river Teign. East Teignmouth church is near the sea-shore; it has been rebuilt within a few years on an enlarged scale: the former church was an antient fabric, with a massive tower, and had some windows and other parts of Norman architecture. West Teignmouth church is large and handsome; it was built under an Act passed A.D. 1815. There is an Independent meeting-house in East Teignmouth; also a theatre, assembly, coffee, and billiard rooms. The bridge over the Teign, opened in 1827, is the longest in the united kingdom, being 1671 feet long, 429 feet longer than Waterloo Bridge. A new market-place has been built of late years. The market is in East Teignmouth; it is on Saturday for provisions of all kinds: there are three fairs also in East Teignmouth. The livings of East and West Teignmouth are perpetual curacies. The yearly value of East Teignmouth is 127*l.*; West Teignmouth is now united with the vicarage of Bishop's Teignton, the yearly value of which is 334*l.*, with a glebe house. Teignmouth contained in 1833 five infant schools with 134 children, sixteen day-schools with 570 children, and two Sunday-schools with 199 children. Of the day-schools one was partly supported by a small endowment, and another was on the so-called 'national' system. The cliffs near Teignmouth rise in some parts to the height of from 150 to 200 feet.

Topsham is in the hundred of Wonford, three and a half miles south-east of Exeter, on the left or eastern bank of the Ex, at the junction of the Clist. The parish comprehends an area of 1740 acres, and had in 1831 a total population of 3184. No manufacture is carried on at Topsham. The town consists almost entirely of one street of irregular breadth, and about a mile in length, extending along the bank of the Ex, with a quay at the lower end of it. At the back of the town is a bridge over the Clist, communicating with the road from Exeter to Lympstone and Exmouth. The houses are generally of mean appearance; but some of them are handsome. The end towards the quay, called the Strand, is inhabited chiefly by persons of property, of whom there are many at Topsham. The houses here command a fine view of the Ex, with the opposite country, backed by the lofty heights of Great and Little Haldon. The church is in the centre of the town, on a high cliff next the river. There are places of worship for Presbyterians, Independents, and Wesleyan Methodists. Topsham was formerly considered as the port of Exeter: lately the facilities for vessels getting up to Exeter have been increased. There is a communication by steam-boats between Topsham and London. The market is on Saturday, and there is one small fair in the year.

The living of Topsham is a perpetual curacy in the gift and the peculiar jurisdiction of the dean and chapter of Exeter: its yearly value is 227*l.*

The number of schools in 1833 was as follows: twenty-four day, or boarding and day schools, with 636 children; and four Sunday schools, with 402 children. One of the day schools was a National school, and contained 90 boys and 77 girls.

When Exeter was besieged by the Royalists under prince Maurice, in the civil wars of Charles I., A.D. 1643, the earl of Warwick, who commanded the parliamentary fleet, in attempting to relieve the town, battered down a fort at Topsham, and killed seventy or eighty men. Topsham was antiently called Apsham or Apsom.

Torrington (distinguished from Little Torrington and Black Torrington by the epithet Great) is a municipal borough and market-town in the hundred of Fremington,

about thirty-six miles from Exeter, by Crediton, Chulmleigh, and Cranford Moor. The borough is co-extensive with the parish, which comprehends an area of 3640 acres. The total population in 1831 was 3093. The town is situated on a hill, on the northern or right bank of the Torridge, over which there is a bridge communicating with the little suburb of Taddy Port. The church is in a central situation. Torrington castle stood on the south side of the town, on a steep eminence, overlooking the Torridge; it was built by Richard de Merton, A.D. 1340: its site is now a bowling-green.

The principal manufacture carried on in Torrington and the country round is that of gloves; this branch of industry was in 1834 in a very flourishing state. The market is held on Saturday, for corn and butchers' meat; there are three fairs in the year, and a great cattle-market on the third Saturday in March.

The quarter sessions and petty sessions are regularly held; the court of record has gone into disuse. The new act assigns to Torrington four aldermen and twelve councillors.

The living of Torrington is a vicarage, united with the perpetual curacy of the neighbouring parish of St. Giles in the Wood: their joint yearly value is 162*l.*: they are in the gift of Christ Church College, Oxford. There were in 1822 places of worship for Presbyterians, Wesleyans, and Baptists. (Lysons.)

The number of schools in 1833 was as follows:—three infant schools, with 112 children; seven day schools (one partly endowed, and one partly supported by subscription), with 322 children; and three Sunday schools, with 383 children. There are two sets of almshouses, one for six poor persons, unendowed; another for eight poor persons, with an endowment.

In February, 1646, the Royalists under Lord Hopton were attacked at Torrington by the Parliamentary forces under Fairfax, and entirely defeated. This defeat was the death-blow to the Royalist cause in the west. Torrington gives the title of Viscount to the family of Byng.

Uffculm, or Uffculme, is in Bampton hundred, on the right or north-west bank of the river Culm, a feeder of the Ex, about sixteen or seventeen miles north-north-east from Exeter. The parish comprehends an area of 5920 acres, and had, in 1831, 416 inhabited houses and 2082 inhabitants: of the adult male population nearly half were engaged in agriculture. Uffculm was in the middle, and even towards the close of the last century, a considerable manufacturing town; a great quantity of serge was made and exported to Holland by the Tiverton merchants. Flannels were afterwards made, but at present the manufactures have ceased. The market is on Wednesday, and there are three fairs in the year, but the fairs have all declined. The church, dedicated to St. Mary, contains some antient monuments and a rich wood screen. There are places of worship for Independents and particular Baptists. The living at Uffculm is a vicarage, of the yearly value of 350*l.*; the rectory forms the corps of a prebend in Salisbury Cathedral; the prebendary is the patron of the vicarage. There were at Uffculm in 1833 nine day-schools and one evening-school with 144 children, and three Sunday-schools with 253 scholars. One of the day-schools is a grammar school, with an endowment worth from 70*l.* to 80*l.* a year, but it contained in 1833 only two scholars.

Beside the above market-towns, there are a few other places in Devonshire which are entitled to a brief notice.

Combe Marten is in Braunton hundred, on the north coast, about five miles east of Ilfracombe. It had in 1831 a population of 1031 inhabitants. It was formerly known for the growth of excellent hemp and the manufacture of shoemaker's thread, but these branches of industry have been given up. The trade of the place is inconsiderable. Welsh coal is imported, and corn and bark are exported: lime is burnt in considerable quantity. The market has been long discontinued: the living is a rectory, of the yearly value of 387*l.*, with a glebe house. The Wesleyans have a place of worship here.

Hartland is an extensive parish in Hartland hundred: it contains several villages. The church is in the village of Stoke, and the market was held in that of Harton. The market-house is standing, but no weekly market has been held for half a century. There is a great market or fair for cattle on the second Saturday in March, and two cattle fairs in the year. At Hartland Pier, near Hartland Point, corn is exported, and coal and limestone imported. The living of Hartland is a perpetual curacy in the gift of the governors of the Charter-house in London; it is worth 97*l.* a

year. It is said there were formerly eleven chapels in the parish. The Independents have a meeting-house. Hartland Abbey was founded by the wife of earl Goodwin for secular priests; but in the time of Henry II. these seculars were changed into an abbot and convent of Black or Augustinian canons. The revenues of this house at the dissolution were 306*l.* 13*s.* 2*d.* according to Speed, and 306*l.* 3*s.* 2*d.* according to Dugdale. Some portion of the cloisters of the abbey remain; they are in the early English style. The population of the parish in 1831 was 2143. There were in 1833 seven day-schools, with 179 children.

Bradninch, a borough between Collumpton and Exeter, is in Hayridge hundred. It had in 1831 a population of 1524, more than half of which was agricultural. The market has been disused beyond the memory of those now living. The boundaries of the borough are identical with those of the parish, and include an area of 4320 acres. The town consists principally of one street, extending for above half a mile along the Exeter and Collumpton road; the footpaths are paved. The quarter sessions, petty sessions (monthly), and court of record are kept up. There is a guild-hall with a small gaol under it, which has been lately rebuilt. The church is near the middle of the town, and has a rich screen across the nave and aisles. The living is a perpetual curacy of the yearly value of 102*l.*, with a glebe house in the gift of the Dean and Chapter of Windsor. There is a Baptist meeting-house, with which a Sunday-school is connected. There were in 1833 three day-schools and one boarding-school at Bradninch, containing sixty or eighty children. Beer Alston is in the parish of Beer Ferris or Ferrers, and in the hundred of Roborough; it is between the Tamer and the Tavy. It had no market for many years, but was up to the Reform Act a parliamentary borough. [BEER ALSTON.] Thorncombe, in a detached part of the county, included between Dorsetshire and Somersetshire, had formerly a market, which was discontinued about the year 1770. The population of the parish, which is large and includes several villages, was, in 1831, 1368. In this parish stood Ford Abbey, to which an abbot and twelve Cistercian monks were removed A.D. 1141. This abbey at the dissolution was valued at 381*l.* 10*s.* 6*d.* gross yearly income, or 374*l.* 10*s.* 6*d.* clear. There are some remains of the monastic buildings: the chapel has a groined roof (early English) and some late Norman arches; the hall and cloisters are of rich late perpendicular architecture. Silvertown is between the Ex and the Culm, seven miles north of Exeter, in Hayridge hundred. There has been no market since 1785. The church, which lies a little back from the principal street, is a handsome edifice in the perpendicular style. The population of the parish in 1831 was 1389. Sheepwash or Shipwash is in Shebbear hundred on the north bank of the Torridge, a short distance west by north of Hatherleigh. The market was considerable in the middle of the last century, but since the latter end of that century it has been discontinued. The parish is not large, and had in 1831 only 446 inhabitants. Exmouth, the situation of which is indicated by its name, is a place much resorted to as a bathing-place. It is in East Budleigh hundred, and about eight miles south of Exeter. The population of the joint parishes of Littleham and Exmouth in 1831 was 3189. Exmouth was in the reign of King John one of the principal ports of the county, and in 1347 it furnished 10 ships and 193 mariners for the expedition against Calais. In the civil war of Charles I. Exmouth fort was garrisoned for the King, but taken by the Parliamentarians. There is a national school, for which Lord Rolle built a school-room, and to which Lady Rolle bequeathed an endowment. Dawlish, between the mouths of the Ex and the Teign, is also frequented as a bathing-place. It is in Exminster hundred, and had in 1831 a population of 3151. Torquay, also a fashionable watering-place, is on the north side of Torbay, in the parish of Tor Mohun, or Moham in Haytor hundred. Tor Mohun parish had in 1831 a population of 3582. A market-house has been built, and there are hotels and bath rooms, terraces, and detached cottages. The inhabitants are engaged in the Newfoundland and home fisheries, and carry on some coasting trade. Paignton, population, in 1831, 1960, formerly a market-town, is on the west side of Torbay. Clovelly, on the north coast, is a village remarkable for its picturesque situation and appearance. The houses are built on the face of a steep rock. There is a pier at Clovelly. The inhabitants are engaged in fishing. Population, in 1831, 907.

Though none of the above places (except perhaps Tor-

quay) has a market now, several of them are put down in the maps as market-towns.

Divisions for Ecclesiastical and Legal Purposes.—From the introduction of Christianity among the Anglo-Saxons to the year 703, the southern part of England, from Kent to Cornwall, was under one bishop. Upon the ecclesiastical division which took place in 703 (in the reign of Ina, king of Wessex), Devonshire became part of the diocese of Sherborne. About A. D. 910 (in the reign of Edward the Elder, son of the great Alfred) Devonshire formed a diocese of itself, the see being at Crediton. About the year 1040, in the reign of Harold I., or Hardicanute, Cornwall, which had previously formed the separate diocese of St. Germans, was united with Devonshire, and the see was soon afterwards, A. D. 1050 (in the reign of Edward the Confessor), removed to Exeter, where it has ever since continued. That part of the diocese which is in Devonshire is divided into three archdeaconries, which are subdivided into twenty-three rural deaneries, as follows:—I. Archdeaconry of Exeter, in the eastern part of Devon, comprehending the rural deaneries of (1) Aylesbeare, (2) Cadbury, (3) Christianity, or Exeter, (4) Dunkeswell, (5) Dunsford, (6) Honiton, (7) Kenne, (8) Plymtree, (9) Tiverton. II. Archdeaconry of Barnstaple, in the north, comprehending the rural deaneries of (10) Barum, or Barnstaple, (11) Chulmleigh, (12) Hertland, (13) Shirwell, (14) South Molton, (15) Torrington. III. Archdeaconry of Totness, in the south and west, comprehending the rural deaneries of (16) Holsworthy, (17) Ipplepen, (18) Moreton, (19) Oakhampton, (20) Tamerton, (21) Tavistock, (22) Totton, or Totness, (23) Woodleigh. The office of dean rural is an efficient one; the deans are appointed yearly at the visitations.

The number of benefices in the county is given by Messrs. Lysons (*Magna Britannia*) at 471, of which 258 are rectories, 130 vicarages, 42 donatives, or curacies, and 41 parochial chapelries. There are several chapels of ease. Several of the churches are in the peculiar jurisdiction of the bishop, the dean, the dean and chapter, or the vicars choral of Exeter; one is in the peculiar jurisdiction of the dean and chapter of Salisbury. The diocese of Exeter is in the ecclesiastical province of Canterbury.

Devonshire is included in the western circuit: the assizes and quarter sessions for the county are held at Exeter, which city is a county of itself, having been made so by statute 2 & 3 Edward VI. The stannary laws [CORNWALL] have been in force from a very early period in the mining district in the south-west part of the county. The stannary towns are Ashburton, Chagford, Plympton, and Tavistock. The stannary prison was at Lidford Castle, now a ruin.

The county returns four members to parliament, two for the northern and two for the southern division. The election for the northern division is held at South Molton; the polling stations are South Molton, Collumpton, Barnstaple, Torrington, Holsworthy, and Crediton. The election for the southern division is held at Exeter, and the polling stations are Exeter, Plymouth, Honiton, Newton Abbot, Kingsbridge, Tavistock, and Oakhampton. The city of Exeter returns two members, as do the following boroughs: Barnstaple, Devonport, Honiton, Plymouth, Tavistock, Tiverton, and Totness. The boroughs of Ashburton and Dartmouth return one each; making the total number of members for the county, city and boroughs, twenty-two, four less than before the Reform Act. Beer Alston, Bradninch, Crediton, Fremington, (near Barnstaple), Lidford, (between Tavistock and Oakhampton), Modbury, South Molton, Oakhampton, Plympton, and Great Torrington, once sent members to parliament. Torrington lost the right in consequence of the inhabitants finding the maintenance of their representative too heavy a burden, and petitioning to be excused: it is said that the same was the case with several of the other boroughs; but there are no records to show this. Beer Alston, Oakhampton, and Plympton were disfranchised by the Reform Act. Exmouth and Teignmouth sent representatives to the great councils for maritime affairs.

History. Antiquities.—The earliest ascertained inhabitants of this county were the Damnonii (Richard of Cirencester), Dumnonii or Dumnunnii (*Itin. Antonin.*), or Δουμνονιοι (Ptolemy). It has been disputed whether these were the original Celtic inhabitants, or whether they were Belgic invaders who drove out a Celtic people (the Cimbri of Richard of Cirencester, as some think), who had previously occupied the country. The Cimbri, according to Richard,

inhabited the country west of the river Uxella (the Parret); their territory therefore probably included the north part of Devonshire. We have no authentic accounts of any conflict between the Damnonii, or Cimbri, and the Romans during the conquest of Britain by the latter: Geoffrey of Monmouth speaks of a drawn battle near Exeter between Vespasian, afterwards emperor, and the Briton, Arviragus; but his authority is worth little. The many antient encampments in Devonshire mark it as the scene of early encounters: some of these camps are evidently Roman. After the Roman conquest Devonshire was included in the province of Britannia Prima.

Of this remote period there are many remains. Circular enclosures formed by low stone walls occur in various parts of Dartmoor. Grimpspound, as it is called, about three miles from the village of Manaton, on the east side of the moor, is a circular enclosure of three acres: it has two entrances directly facing the north and south: at these points the wall, which appears to have been about twelve feet high, was the thickest. In the enclosure are several circles of stone of twelve feet diameter, especially near the south side of the enclosure. This enclosure has been supposed by some to be a British town, connected with some antient tin works, which may be traced near the spot; by others, a place of religious worship. There are in the parish of Bratton Fleming, between South Molton and Ilfracombe, six upright stones, the remains apparently of an antient circle. The granite tors of Dartmoor are natural. There are some sepulchral stones on Maddocks' Down (south of Combe Marten), and a cromlech at Drew's Teignton, between Exeter and Oakhampton. There seems no reason to trace the name of Drew's Teignton to the Druids, as some have proposed to do; it is more probably derived from Drogo, or Drewe, who possessed the manor in the time of Henry II. Numerous barrows, or tumuli, occur on Haldon, and other downs, particularly in North Devon, and some cairns, or piles of stones. Roman antiquities have been found in some barrows when opened.

Of Roman stations in Devonshire the most important appears to have been Isca Damnoniorum, which the name, and the antiquities discovered, concur in fixing at Exeter. We believe the best modern antiquaries are agreed as to the site of Isca: the earlier antiquaries (Horsley, &c.) were misled by what is now an evident corruption in the *Itinerary* of Antoninus. Another Roman station, Moridunum, or Muridunum (*Itin. Anton.*) is agreed by most to have been in this county, but whether at Hembury, near Honiton, where there is an antient camp, or at Seaton, on the coast, at the mouth of the Axe, is not so clear. Two other stations are mentioned by Richard of Cirencester: 'ad Durium,' (the station on the Durus, or Dart,) supposed to be Totness; and Tamara, the name of which indicates its situation somewhere on the river Tamara (Tamer), and which was probably at Tamerton Folliot, on the æstuary of the river some miles above Devonport. Richard also mentions two British towns, Termolus and Artavia, in the territory of the Cimbri, and probably in the north of Devon. These are identified by the late bishop of Cloyne in Lysons' '*Magna Britannia*,' with the Termonin and Mostevia of the geographer Ravennas. The former of these towns (Termolus) the bishop fixes at Molland Botreaux (between South Molton and Dulverton, Somersetshire), where there is a large antient cairn, and to which a number of roads on all sides point; and the latter is supposed to have been near Hartland point. It has been conjectured that Denbury, near Newton Abbot, is the place called Devionisso by the geographer Ravennas.

An antient British road, afterwards converted by the Romans to their own use, traversed the whole county from east to west, passing near Axminster and Honiton to the camp at Hembury, and by a subsequent bend, to Isca, or Exeter. From Isca, it ran south-west over Haldon and near Newton Abbot to Totness, and from thence west to the Tamara, or Tamer. This road has preserved in Dorsetshire (before it enters Devon) its old British name of the Ikeneld way. Many other roads may be traced. The Roman antiquities found in the county have not been numerous: the principal seem to have been at Exeter, where a tessellated pavement was found, some bronzes, coins, and other remains. Some antiquities have been found at Seaton, and other places.

The name of the British nation, the Damnonii, or Dumnonii, has been (but apparently with little reason) derived by some from two Phœnician words, 'dan,' or 'dun,'

a hill, and 'moina,' mines. The Cornish Britons named the country, 'Dunan;' the Welsh, 'Deuffneynt,' which evidently contains the same elements as the Saxon, Devenascyre, Devnascyre, or Devenshire. The Welsh, Deuffneynt, is defined by Camden to mean 'deep valleys.'

In the Saxon invasion this county became the scene of contest. Cynegils, king of the West Saxons, is said by the Saxon chronicle to have beaten the Britons at Beamdune, supposed to have been Bampton, A. D. 614. Matthew of Westminster speaks of a battle fought A. D. 633, between Penda, king of Mercia, who had besieged Exeter, and Cadwallo, king of the Britons, but his account is hardly consistent with the history of the time. We find no historical notices of Devonshire from this period until the invasions of the Danes.

The pressure of the West Saxons gradually constrained the Britons to retire westward. Devonshire was for a long period debateable ground; it was in great part occupied by the Saxons, but there is reason to think that it was not until the reign of Athelstan, who is said to have defeated Howell, king of Cornwall, near Exeter, A. D. 926, that the Britons were finally compelled to retire beyond the Tamer. Their complete expulsion from Devonshire was probably retarded by the incursions of the Danes, who commonly found them ready to unite with them against the Saxons, the objects of their common hostility. In A. D. 876, 877, the Danes seem to have wintered at Exeter, and were in 877 besieged by Alfred, who compelled them to make peace, and to give hostages for the observance of it. In A. D. 878, when Alfred had been compelled by a Danish invasion to conceal himself, Ubbo or Hubba, one of the sons of Ragnar Lodbrog and one of the chiefs of the invaders, landed in the north of Devon, and blockaded Kynwith castle, near Appledore. Odun (who is styled earl of Devon,) who occupied the castle, made a vigorous sally just about daybreak, slew Ubbo and nearly 1000 of his men, and captured the magical standard of the Danes, woven by the sisters of Ubbo, and worked with the figure of a raven. In A. D. 894 the Danes were again in Devonshire; those of them whom Alfred had settled in East Anglia and Northumbria, induced by Hastings, who was then infesting England, took ship, and sailing round the headlands of Kent and along the Channel, besieged Exeter; but on the approach of Alfred's army they fled to their ships.

The great battle of Brunanburh, which has been usually placed in Northumberland, has been by others supposed to have been fought near Axminster in Devonshire. This decisive conflict gave to Athelstan the undisputed possession of England, and a nominal supremacy over Wales and Scotland. Axminster is supposed to have derived its present name from a college of priests founded here by Athelstan, to pray for the souls of those who fell in the conflict, and who were buried in the cemetery of Axminster: there were five kings and eight earls among them.

In A. D. 997 the Danes came up the Tamer, ravaged the country up to Lidford, and burnt Tavistock Abbey: in A. D. 1001 they landed at Exmouth and besieged Exeter, but in vain: they however defeated the king's army, and burnt several villages. In A. D. 1003 they again besieged Exeter, took it through the treachery or negligence of the governor, and nearly destroyed it.

When William of Normandy attacked England, his second campaign was in the west. Exeter yielded on his approach. In the next two years, when the Saxons of the neighbourhood rose in revolt, or rather renewed the struggle for independence, under the sons of Harold, who had fallen at Hastings, the citizens refused to admit them. William sent some troops to relieve the city, and the Saxons were defeated with great slaughter.

The coasts of Devonshire were, about this time, laid waste by the Irish, and the civil broils which arose during the next hundred years between the children and descendants of the Conqueror rendered Devonshire the scene of contest. The succeeding centuries are marked by few historical events, except occasional attacks by the French on the towns on the coast, and some contests of inferior moment during the wars of the Roses. The nobility of the county were divided between the rival houses; the Courtenays, earls of Devon, were Lancasterians, and three brothers who successively enjoyed the title, fell in the field or died on the scaffold.

In the rebellion of the Cornish men under Lord Audley and Flammoek [CORNWALL], and in the rebellion under Perkin Warbeck, Exeter was the object of attack, but in both cases the attack failed. The last siege was raised by Courtenay, earl of Devon, attended by several Devonshire

knights, and the *posse comitatus*. Warbeck retired to Taunton.

Of the troubled periods to which the foregoing sketch refers, Devonshire contains several memorials in the baronial castles, the ruins of which are still in existence. At Exeter, Plympton, Oakhampton, and Tiverton were castles, all of which belonged to the Courtenays. [EXETER; TIVERTON.] Some of the walls of the keep of Plympton castle yet remain; and some scanty ruins of that of Oakhampton. Berry Pomeroy castle, near Totness, is an antient mansion on the brow of a steep hill in a well wooded country; it was the seat first of the Pomeroyes, afterwards of the Seymours; [BERRY POMEROY.] Compton castle near Torbay, and Afton castle near Chulmleigh, are still standing and converted into farm-houses; and there are remains of Gidley castle; Hemyock castle, near the upper waters of the Culm; Dartmouth castle; Kingswear castle, near Dartmouth; and Lidford castle, formerly the stannary prison, between Tavistock and Oakhampton. Of antient mansion houses, Dartington near Totness, built in the reign of Richard II., about the end of the fourteenth century, and an old mansion at Bradley near Newton Bushel, built in the fifteenth century, are among the most remarkable.

When the alteration of the church service took place at the Reformation, A. D. 1549, great disturbances broke out in Devonshire. They began at Sampford Courtenay, between Oakhampton and Chulmleigh, and gradually assumed a serious aspect, as some of the gentry joined in the revolt. The spirit of disaffection spread into Cornwall. Exeter was besieged by the rebels; and it was not until several severe actions had taken place, that Lord Russell, who had been sent down to suppress the revolt, succeeded in doing so. In 1554 Exeter was occupied by Sir Peter and Sir Gawen Carew, who had taken up arms to oppose the coming of Philip of Spain.

Of the monastic establishments of Devonshire, Tavistock Benedictine Abbey; Buckland, Buckfastre, Dunkeswell, Ford, and Newenham, Cistercian abbeys; Plympton and Hertland, the former a priory and the latter an abbey of Augustinian canons; and Tor abbey for Premonstratensian canons, were the chief. The ruins of these buildings are inconsiderable: the chapel and other parts of Ford abbey on the river Axe; the refectory and abbot's hall and the gate-house at Tavistock; part of the conventual church of Tor abbey; and some remains of Buckland, Hertland, and other establishments are yet standing. There are considerable remains of St. Nicholas's priory at Exeter; the crypt which has massive Norman arches has been converted into a kitchen.

In the great civil war of Charles I. the county seems generally to have embraced the cause of the parliament. Plymouth was seized by the townsmen during the absence of the governor appointed by the king, and the earl of Ruthen was soon after made governor. Exeter was the head-quarters of the earl of Stamford, the parliamentary general. The defeat of the parliamentarians at Bradock Down, near Liskeard, [CORNWALL] early in 1643, raised the confidence of the royalists, but they suffered some severe checks in different parts of the country, and the predominance of the parliamentarians was restored. The defeat of Lord Stamford at Stratton [CORNWALL], 16th May, 1643, again turned the current in favour of the royalists, whose superiority was confirmed by the arrival and activity of Sir John Berkeley, sent with a reinforcement by the king, and by the subsequent arrival of Prince Maurice, the king's nephew. The royalists besieged Exeter, which the earl of Warwick who commanded the fleet for the parliament was unable to relieve. Colonel Digby, a royalist, defeated the parliamentarians at Torrington; and Barnstaple, Bideford, and a strong fort at Appledore, which were held for the parliament, surrendered. Exeter also was compelled to surrender about the same time. Had Prince Maurice marched to Plymouth, he might perhaps have gained possession of that important station, then the greatest trading port in the west of England, but he lost a month in besieging Dartmouth, which he took; his troops were diminished by sickness, and the garrison at Plymouth was reinforced. When the town was at last blockaded it was without success; two assaults made in December, 1643, were repulsed; and the siege was for a time abandoned. In the spring of 1644, several fresh attempts were made upon it, but with no better fortune. In 1644 the earl of Essex with his army reached Devonshire, but no great or decisive event took place, until Essex marched into Cornwall, where his infantry was obliged

to capitulate to the king, who had followed him thither. [CORNWALL.] The king, returning from Cornwall, summoned Plymouth to surrender; and on its refusal, Sir Richard Grenville was left to carry on the siege. In January, 1645, Sir Richard made an assault, which was repulsed, and the remainder of the year was marked by a series of disasters, which may be in no small degree ascribed to the misconduct and dissensions of the king's generals. In October, 1645, Sir Thomas Fairfax, commander-in-chief for the parliament, entered the county with his army, and in the course of the following winter and spring entirely put down the opposite party. Mount Edgecumbe surrendered on the 21st April, 1646, and was the last post held for the king in Devonshire, except Charles fort at Salcombe Regis, which did not surrender till the following June.

At the revolution of 1688, the Prince of Orange landed in Torbay, November 5th: on the 8th he made a public entry into Exeter, where he remained for some days before any of the principal people of the county joined him: on the 21st he quitted Exeter on his march to London. A small garrison under the command of Sir Edward Seymour was placed in Exeter.

Teignmouth was burnt by the French, A.D. 1690. In 1719, upon the apprehension of a French invasion, an encampment was formed on Clist Heath, four or five miles north-east of Exeter. In 1779 the appearance of the combined French and Spanish fleets off Plymouth caused great alarm, and the prisoners of war were removed to Exeter. In 1798, upon the alarm of a French invasion, several regiments of volunteers were raised, artillery was brought from Plymouth for the defence of Exeter, and placed in an antient intrenchment on Woodbury Down, a few miles south-east of Exeter, where a camp was formed. Similar measures were taken upon the renewal of the alarm in 1803.

STATISTICS.

Population.—Devonshire is an agricultural county; it has but few manufactures, but many of its inhabitants are employed in quarrying stone, or in obtaining some other of the valuable minerals it contains. It ranks the twenty-fourth on the list of agricultural counties, and in this respect has remained stationary since 1811. Of 116,188 male inhabitants twenty years of age and upwards, in 1831, 47,995 were engaged in agricultural pursuits, 35,311 of whom were labourers; only 1,221 were employed in manufactures or in manufacturing machinery; and there were 14,307 labourers not agricultural. Of those employed in manufactures about 700 were engaged in the woollen manufacture, and were distributed at Axminster, Ashburton, Buckfastleigh, Chagford, Cullumpton, North and South Molton, and at North Tawton; glove-making employs about 70 at Great Torrington; lace-making about 70 at Barnstaple, Pilton, and Tiverton; the rest are too miscellaneous for particular description. About 90 are employed in different manufactures in the city of Exeter.

The population of Devonshire, at each of the four enumerations during the present century, was:—

	Males.	Females.	Total.	Inc. per cent.
1801	157,240	185,761	343,001	
1811	179,553	203,755	383,308	11.75
1821	208,229	230,811	439,040	14.54
1831	235,789	258,689	494,478	12.55

Showing an increase between the first and last periods of 151,477, or a little more than 44 per cent., which is 13 per cent. below the whole rate of increase throughout England.

The following table is a summary of the population, &c., of every hundred, as taken at the census of 1831:—

HUNDREDS, &c.	HOUSES.				OCCUPATIONS.			PERSONS.			
	Inhabited.	Families.	Building.	Uninhabited.	Families chiefly employed in agriculture.	Families chiefly employed in trade, manufactures, and handicraft.	All other families not comprised in the two preceding classes.	Males.	Females.	Total of persons.	Males twenty years of age.

Totals	81,999	101,911	1,381	4,220	35,505	33,339	33,067	235,789	258,689	494,478	116,188

County Expenses, Crime, &c.—The sums expended for the relief of the poor at the four dates of

	£.	s.	d.
1801 were	124,022	7	2
1811 „	217,757	11	4
1821 „	207,686	9	5
1831 „	233,074	9	0

The sum expended for the same purpose in the year ending March 25, 1836, was 172,405*l.* 16*s.*; and assuming that the population had increased at the same rate of percentage since 1831 as in the ten years preceding that period, the above sum gives an average of 6*s.* 5½*d.* for each inhabitant. These averages are below those for the whole of England and Wales.

The sum raised in Devonshire for poor's rate, county-rate, and other local purposes, in the year ending the 25th of March, 1833, was 260,320*l.* 10*s.*, and was levied upon the various descriptions of property as follows:—

	£.	s.
On land	190,707	11
Dwelling-houses	60,408	17
Mills, factories, &c.	5,404	2
Manorial profits, navigation, &c.	3,800	0
	260,320	10

The amount expended was:—

	£.	s.
For the relief of the poor	226,891	11
In suits of law, removal of paupers, &c.	8,030	19
For other purposes	28,518	2
	263,440	12

In the returns made up for the subsequent years, the descriptions of property assessed for local purposes are not distinguished: 250,270*l.* 4*s.*, 231,766*l.* 6*s.*, and 212,691*l.* 2*s.* were raised in the years 1834, 1835, and 1836 respectively, and the expenditure of each year was as follows:—

	1834.	1835.	1836.
	£.	£.	£.
For the relief of the poor	210,825	189,917	172,405
In suits of law, removals, &c.	7,507	6,251	6,108
Payment for or towards the county rate	26,539	15,188	15,149
For all other purposes		18,051	16,390
Total money expended	244,871	229,408	210,053

The saving effected in the whole sum expended in 1836, as compared with the expenditure of 1834, is therefore rather more than 15 per cent.; but the saving on the sum expended for the relief of the poor is about 18½ per cent. in 1836, as compared with the expenditure of 1834.

The number of turnpike trusts in Devonshire is 28, as ascertained in 1834; the number of miles of road under their charge was 782; the annual income of that year, arising from the tolls and parish composition, was 61,374*l.* 12*s.* 11*d.*, and the annual expenditure 61,786*l.* 17*s.* 1*d.*

The county expenditure in 1834, exclusive of that for the relief for the poor, was 14,733*l.* 14*s.* 11*d.*, disbursed as follows:—

	£.	s.	d.
Bridges, buildings, and repairs, &c.	2,851	2	5
Gaols, houses of correction, &c., and maintaining prisoners, &c.	4,720	15	4
Shire halls and courts of justice—building, repairing, &c.	265	5	1
Lunatic asylums	181	19	6
Prosecutions	3,517	17	5
Clerk of the peace	682	2	7
Conveyance of prisoners before trial	819	15	5
„ of transports	210	16	6
Vagrants—apprehending and conveying	147	10	0
Constables—high and special	16	8	10
Coroner	459	16	11
Miscellaneous	860	4	9

The number of persons charged with criminal offences in the three septennial periods ending with 1820, 1827, and 1834, were 2347, 2741, and 3106 respectively; making an average of 335 annually in the first period, of 391 in the second, and of 443 in the third. The number of persons

tried at quarter-sessions in each of the years 1831, 1832, and 1833, in respect to which any costs were paid out of the county rates, were 230, 258, and 193 respectively. Among the persons charged with offences, there were committed for—

	1831.	1832.	1833.
Felonies	212	245	185
Misdemeanors	18	13	8

The total number of committals in each of the same years was 203, 248, and 194, respectively.

	1831.	1832.	1833.
The number convicted was	144	195	139
„ acquitted	71	42	28
Discharged by proclamation	35	37	34

In 1835, at the assizes and sessions 518 persons were charged with crimes in Devonshire; of which number 55 were charged with offences against the person, 37 of which were common assaults; 19 for offences against property, committed with violence; 401 for offences against property, committed without violence; 10 for arson; 1 for forgery; and 13 for uttering counterfeit coin; 9 for riot and prison breaking; and 10 for misdemeanors. Of the whole number committed, 326 were convicted, and 191 acquitted, or no bill was found. Of those convicted, 29 were transported for life, 15 for 14 years, and 48 for 7 years; 1 was to be imprisoned for 3 years and above 2 years, 2 for 2 years and above 1 year, 31 for one year and above 6 months, and 192 for 6 months or under; 2 were whipped, 4 fined, and 1 discharged on sureties. Of the offenders, 381 were males, and 137 females. Of the whole number of offenders, 193 could read and write, 176 could read only, 122 could neither read nor write, and the degree of instruction of 27 could not be ascertained.

The number of persons qualified to vote for the county members of Devonshire is 18,835, being 1 in 26 of the whole population, and 1 in 6 of the male population, 20 years of age and upwards, as taken in 1831. The expenses of the last election of county members to parliament were to the inhabitants of the county 139*l.* 15*s.* 2*d.*, and were paid out of the general county rate.

There are five savings-banks in Devonshire. The number of depositors, and amount of deposits on the 20th November, were respectively in—

	1832.	1833.	1834.	1835.
Number of depositors	26,996	28,521	30,264	31,973
Amount of deposits	£863,290	897,028	947,326	1,001,628

The various sums placed in the savings-banks in 1834 and 1835 were distributed as follows:—

	1834.	1835.
	Depositors.	Deposits.
Not exceeding £20	16,968	£106,335
„ 50	7,396	228,941
„ 100	3,543	246,202
„ 150	1,347	163,072
„ 200	680	119,499
Above 200	330	83,277
Total	30,264	£947,326

Education.—The following particulars are obtained from the parliamentary returns on education made in the session of 1835:—

	Schools.	Scholars.	Total.
Infant Schools	117		
Number of infants at such schools; ages from 2 to 7 years:—			
Males		770	
Females		838	
Sex not specified		923	
			2,531
Daily Schools	1,772		
Number of children at such schools, ages from 4 to 14 years:—			
Males		14,163	
Females		19,596	
Sex not specified		18,681	
			52,440
Schools	1,889		
Total of children under daily instruction			54,971

Sunday Schools	599
Number of children at such schools, ages from 4 to 15 and 16 years:—	
Males	16,262
Females	17,952
Sex not specified	9,128
	43,342

Assuming that the population between 2 and 15 years increased in the same ratio as the whole of the population between 1821 and 1831, and has continued to increase in the same ratio since, the number between those ages living in Devonshire in 1834 must have been 163,256. A large number of the scholars attend both daily and Sunday schools. Fifteen Sunday-schools, containing only 433 scholars, are in places where no other schools are established, but in all other places where schools are returned there are both Sunday and daily schools. Ninety-four schools are Sunday as well as daily schools, and are attended by 5788 children, and duplicate entry is known thus far to be created, but in what greater number cannot be well ascertained. Making allowance therefore for the probable great diminution of the number of children returned as receiving instruction, perhaps not more than half of the population between 2 and 15 are receiving instruction in Devonshire.

Maintenance of Schools.

Description of Schools.	By endowment.		By subscription.		By payments from scholars.		Subscrip. and pay- ment from scholars	
	Schls.	Scho- lars.	Schls.	Scho- lars.	Schls.	Scho- lars.	Schls.	Scho- lars.

Sunday Schools	14	1069	526	39,181	14	390	45	2702
Total.	178	5835	572	47,256	1420	35,814	168	9408

The schools established by Dissenters, included in the above statement, are:—

	Schools.	Scholars.
Infant Schools	2	50
Daily „	25	1026
Sunday „	171	17,270

The schools established since 1818 are:—

Infant and other daily schools	809	26,313
Sunday Schools	476	33,950

Eighty-three boarding-schools are included in the number of daily schools given above. No school in this county appears to be confined to the children of parents of the Established Church, or of any other religious denomination, such exclusion being disclaimed in almost every instance, especially in schools established by Dissenters, with whom are here included Wesleyan Methodists, together with schools for the children of Roman Catholic parents.

Lending libraries of books are attached to 100 schools in this county.

DEW is the moisture which, when the surface of the ground is colder than the atmosphere, is deposited from the air, in the form of minute globules, on the surfaces of bodies in contact with it. The difference of temperature which exists between day and night produces a variation in the quantity of water which the air contains. The water, when precipitated from the air instead of appearing as a vapour, is deposited on the earth in minute globules, and the air preserves its transparency; this constitutes a difference between fog and dew. When the air contains so little moisture that it can retain it during the lower temperature of the night, no dew is formed.

It is difficult to pronounce as to the whole of the causes which produce dew; but the principal cause is the cooling of the air: when the cold is extremely great the dew freezes and then produces what is called hoar-frost.

It is remarked by Aristotle* and by other writers that dew appears only on calm and serene nights. This observation, according to Dr. Wells, is not to be received in its strictest sense, as he has frequently found a small quantity of dew on grass, both on windy nights, if the sky was clear or nearly so, and on cloudy nights, if there was no wind. If, indeed, the clouds were high, and the weather calm, he has sometimes seen on grass, though the sky was entirely hidden, no very inconsiderable quantity of dew. Again, stillness of the atmosphere is so far from being necessary for the formation of this fluid, that its quantity has seemed to Dr. Wells to be increased by a very gentle motion in the air: but he says, 'I can aver, after much experience, that I ne-

ver knew dew to be abundant, except in serene weather,' and 'dew has never been seen by me on nights both cloudy and windy.*'

Dr. Wells remarks that, during nights which are equally clear and calm, dew often appears in very unequal quantities, even after due allowance has been made for any difference in their lengths: thus it is more abundant shortly after rain than during a long season of dry weather. It is generally more abundant during southerly and westerly winds than those which blow from the north and the east; but this remark, of course, only applies to particular localities. To the greater or less quantity of moisture in the atmosphere, at the time of the action of the immediate cause of dew, are likewise to be referred several other facts respecting its copiousness; these are thus stated by Dr. Wells (p. 10):

'In the first place, dew is commonly more plentiful in spring and autumn than in summer; the reason is, that a greater difference is generally found between the temperatures of the day and the night in the former seasons of the year than in the latter. In spring this circumstance is prevented often from having a considerable effect by the opposite influence of northerly and easterly winds; but during still and serene nights in autumn dew is almost always highly abundant.

'In the second place, dew is always very copious on those clear and calm nights which are followed by misty or foggy mornings: the turbidness of the air in the morning showing that it must have contained during the preceding night a considerable quantity of moisture.

'Thirdly, I have observed dew to be unusually plentiful on a clear morning which had succeeded a cloudy night. For the air having, in the course of the night, lost little or no moisture, was in the morning more charged with watery vapour than it would have been if the night had also been clear.

'Fourthly, heat of the atmosphere, if other circumstances are favourable, which, according to my experience, they seldom are in this country, occasions a great formation of dew. For, as the power of the air to retain watery vapour in a pellucid state increases considerably faster, while its temperature is rising, than in proportion to the heat acquired, a decrease of its heat, in any small given quantity, during the night, must bring it, if the temperature be high, much nearer to the point of repletion before it be acted upon by the immediate cause of dew, than if the temperature were low.

'In the last place, I always found, when the clearness and stillness of the atmosphere were the same, that more dew was formed between midnight and sunrise than between sunset and midnight, though the positive quantity of moisture in the air must have been less in the former than in the latter time, in consequence of a previous precipitation of part of it. The reason, no doubt, is the cold of the atmosphere being greater in the latter than in the prior part of the night.'

With respect to the cause of dew different opinions have been entertained. Aristotle (*Meteor.* i. 10) supposed dew to be a species of rain formed in the lower atmosphere in consequence of the moisture which had been carried up during the day by evaporation being condensed by the cold of the night into minute drops. In 1788 Mr. Wilson of Glasgow published a paper on hoar-frost in the Transactions of the Royal Society of Edinburgh, in which he supposes that cold is occasioned by the formation of the dew. In the course of the same year Mr. Six communicated a paper to the Royal Society in which he imagines that dew proceeds partly from the low temperature of the air through which the dew already formed in the atmosphere had descended, and partly from the evaporation of moisture from the ground, on which his thermometer had been placed.

In a subsequent and posthumous work printed in 1794, the cold of the grass is however attributed, in agreement with the opinion of Mr. Wilson, altogether to the dew deposited upon it. Mr. Wilson and Mr. Six observed, that the production of dew is accompanied with cold on the surface of the ground greater than in the atmosphere a few feet above, the differences being frequently 5, 10, or even more degrees of Fahrenheit's scale. This cold, as has just been mentioned, was considered as the effect of the formation of the dew, though this conclusion involved a very considerable difficulty; for as the transition of a body from the

* Meteor. lib. i. c. x. et De Mundo, c. iii.

* Wells on Dew, 65.]

state of vapour to the fluid or solid form is always accompanied with an evolution of heat, it might be expected that the surface on which the dew is deposited, and still more that on which the hoar frost is formed, would have its temperature raised, and no cause appears why it should be depressed.

Dr. Wells, however, after verifying the facts observed, ascertained by numerous observations and experiments, that the cold at the surface, compared with that of the air above, precedes the formation of dew, and often exists without dew being formed; and that bodies become colder than the neighbouring air before they are dewed. The cold therefore which Mr. Wilson and Mr. Six supposed to be the effect of dew was found by Dr. Wells to be the cause of it.

The question then naturally arises, what are the causes which produce this low temperature of the earth, while the incumbent air is at a higher temperature? This is shown by the experiments and reasoning of Dr. Wells to be caused by the radiation of heat without an equivalent return. The surface of the ground allows a portion of the heat which it receives from the solar rays to escape by radiation when their action is withdrawn: hence its temperature falls; and if the air, holding watery vapour dissolved, rest upon it without much agitation (a circumstance by which, as the constant renewal of warm air imparts heat, the effect would be counteracted), a portion of the vapour will be condensed on the surface, and if the temperature is still lower, will be congealed: thus it is that dew and hoar-frost are formed only when the atmosphere is clear, for the clouds return an equivalent portion of radiant heat.

Dew forms in very different quantities on different substances under the same circumstances; thus on metals it is sparingly deposited; on glass it forms abundantly, as it does also on straw, grass, cloth, paper, and other similar substances. Now as the metals radiate heat imperfectly, and the other bodies mentioned in a much greater degree, they become consequently colder than the metals, and hence condense more vapour into dew.

Animal substances are among those which acquire dew in the greatest quantity; among these Dr. Wells found that swan's-down exhibited the greatest degree of cold in general, and was also most easily managed, as it was used while adhering to the skin of the bird. On other occasions wool was employed, and the following statements are the results of Dr. Wells's experiments with respect to the influence which several differences in the situation, mechanical state, and real nature of bodies have upon the production of dew.

A general fact is, that whatever diminishes the view of the sky, as seen from the exposed body, occasions the quantity of dew which is formed upon it to be less than would have occurred if the exposure to the sky had been complete; two parcels of wool, each weighing ten grains, were placed, one on the middle of a board, and the other to the middle of the underside; the two parcels were an inch asunder, and equally exposed to the action of the air: on weighing the two portions, it was always found that the upper portion had acquired most dew, the greatest difference being twenty grains to four grains.

The following is a tabular view of observations with respect to temperature made by Dr. Wells on the evening of the 19th of August, 1813:—

	6h. 45m.	7h.	7h. 20m.	7h. 40m.	8h. 45m.
Heat of air 4 feet above					
the grass	60½°	60½°	59°	58°	54°
„ wool on a raised board	53½	54½	51½	48½	44½
„ swan's-down on the same	54½	53	51	47½	42½
„ surface of the raised board	58	57	55½	..	..
„ grass plat	53	51	49½	49	42

Sir Robert Barker and Mr. Williams have both given accounts of the process by which ice is formed in Bengal, while the temperature of the air is above 32°; and its production was attributed, by the former altogether, and by the latter in great measure, to cold produced by evaporation. Dr. Wells's experiments however show not only that the evaporation which occurs is insufficient to account for the effect, but that the cold produced by radiation alone will satisfactorily explain it. On the subject of cold produced by radiation, Dr. Wells makes the following curious statement:—‘I had often,’ he says, ‘in the pride of half know-

ledge, smiled at the means frequently employed by gardeners to protect tender plants from cold, as it appeared to me impossible that a thin mat, or any such flimsy substance, could prevent them from attaining the temperature of the atmosphere, by which alone I thought them liable to be injured. But, when I had learned that bodies on the surface of the earth become during a still and serene night colder than the atmosphere by radiating their heat to the heavens, I perceived immediately a just reason for the practice which I had before deemed useless.’ And he follows up this part of the subject by relating some extremely simple experiments in proof of the efficacy of the practice, and in explanation of the effect by the processes of radiation and reflexion of heat.

DEWBERRY, a kind of bramble, the *Rubus cæsius* of botanists, so named because its black shining fruit is covered over by a fine waxy white secretion resembling dew. It forms the type of one of the sections of the European part of the genus *Rubus*, the systematic character being digitate leaves, downy or hairy leafstalks or stems, leaflets green on the under side, and calyx standing erect about the fruit.

DEWSBURY a market-town, parish, and township in the West Riding of the county of York, in the wapentakes of Aggbrigg and Morley, and in the liberty and manor of Wakefield. It is 5 miles west of Wakefield, 8 miles south-west of Leeds, 33 south-west of York, and 187 north-west of London. The antient importance of Dewsbury is connected more with ecclesiastical than with civil history. In the time of the Saxons it was one of the most extensive parishes in England, and comprised an area of 400 square miles, including the present parishes of Thornhill, Burton, Almondbury, Kirkheaton, Huddersfield, Bradford, Mirfield, and Halifax. Dewsbury was the centre from which Christianity was diffused through this part of the island in Saxon times. The name is supposed by some to have been derived from its first Saxon proprietor; others consider that the success of the preaching of Paulinus, the first archbishop of York, caused the place of his residence to be called Duisborough, God's town. The remains of Saxon tombs are still to be seen in the vicarage garden, near the church. Other relics of the same people have also been found, the most remarkable of which exhibits the Saviour in the act of bestowing his benediction. At the east end of the chancel, placed on a cross on the outside of the church, is the following inscription: ‘Paulinus hic prædicavit et celebravit, A.D. 627.’ This is not the identical Saxon wheel-cross, but a fac-simile of it. The church is the mother-church of the district, several neighbouring parishes acknowledging their original dependence by their prescriptive payments. No appearance of Saxon architecture is presented in the existing edifice, which comprises a nave and aisles; a chancel; an octagonal vestry on the north side; and a tower finished with pinnacles at the west end. The living is a discharged vicarage; it is endowed with 200*l.* private benefactions, and 200*l.* royal bounty. Its average gross income is 238*l.* per annum; it is in the patronage of the crown. There is a second church in the township of Dewsbury, which was erected by the parliamentary commissioners in 1827; the dissenting places of worship in the township are, two for Wesleyan Methodists, one for the New Connexion Methodists, one for Primitive Methodists, one for Independents, and one for Quakers; there are several other dissenting chapels in the parish.

The public educational establishments at Dewsbury are Wheelwrights' Charity, a school recently erected under a decree of the Court of Chancery at an expense of 600*l.*, for the instruction of 100 boys and 100 girls on the national system; the Dewsbury charity school, containing 100 boys, which has an endowment of 100*l.* per annum (the master's salary is 80*l.* a year); an infants' school; and several daily-schools. The Sunday-schools of Dewsbury are attached to different places of worship, and instruct about 1500 children.

The town is pleasantly situated at the base of a hill rising from the river Calder. It has several good streets, and is lighted with gas. As a place of manufacture it is rising in importance, and its factories furnish large supplies of blankets, woollen cloths, and carpets. Coal is abundant in the neighbourhood; and the water of the Calder has a high reputation for its fulling properties. The commercial facilities of the town are increased by good roads; and the communication by water is, eastward by the Calder navigation, and westward by the Calder and Huddersfield canal. Thus

access is obtained to Wakefield, Leeds, Selby, and Hull; and by Huddersfield to Manchester, Rochdale, Liverpool, and the other commercial towns in Lancashire. The population of the parish of Dewsbury is as follows: Dewsbury 8272; Ossett 5325; Soothill 3849; Hartshead-cum-Clifton 2408; making a total of 19,854. The population of the parish in 1821 was 16,261. The market-day at Dewsbury is Wednesday. There are three fairs in the course of the year. Ossett is a large manufacturing township, midway between Dewsbury and Wakefield; it has a chapel of ease to Dewsbury, and several dissenting places of worship. In the township of Soothill are two villages, called Earls' Heaton and Hanging Heaton, each of which have churches which were erected in 1825-7 by the parliamentary commissioners. Hartshead-cum-Clifton is in the wapentake of Morley; it has a chapel of ease to Dewsbury, in a fine situation, commanding an extensive view of the vale of the Calder. In this township the tomb of the notorious free-booter, Robin Hood, is pointed out. Whether he was an outlaw of noble parentage or of humble birth is not clear; the epitaph upon his tomb designates him as 'Robert, earl of Huntingdon.' (Baines's *Directory of Yorkshire*; Allen's *History of Yorkshire*.)

DE WITT, JOHN, was born at Dort, in the province of Holland, in September, 1625. His father was burgomaster of his native town, and member of the states of Holland, in which capacity he was an opponent of the House of Orange, whose power and influence had been looked upon with jealousy ever since the time of Barneveldt by a considerable party in that province. [BARNEVELDT.] John de Witt, who inherited his father's principles, was made in 1652 grand pensioner of Holland, an office which gave him great influence over the deliberations of the States General or Federal Assembly of the Seven United provinces, in which the vote of the rich and populous province of Holland generally carried with it that of the majority. The time appeared favourable to the anti-Orange party. William II. of Orange, the last stadtholder, had died in 1650, and his posthumous son, afterwards William III. of England, was an infant. The object of De Witt and his party was to prevent in future the union of the offices of stadtholder, captain-general, and high-admiral in one and the same person, which had rendered the princes of the House of Orange almost equal to sovereigns, and which was certainly inconsistent with the title of a republic, assumed by the united provinces. It must however be observed, that each of these provinces, forming a separate state, was in fact governed by an aristocracy, the respective states or legislature of each consisting of the nobles, and the deputies of the principal towns, who were elected by the wealthier burghers; the great majority of the people having no share in the elections. Generally speaking then, the so-called republican party, at the head of which were successively Barneveldt and De Witt, struggled for the continuation or extension of their collective power against the House of Orange, whose influence tended to establish a form nearly monarchical. But that House was popular with the lower classes, and was supported by the majority of the clergy. The nature of the institutions of the United Provinces may be seen in the Act of Union of Utrecht, which was their declaration of independence. During the minority of William III., the office of stadtholder was considered as abolished, and the States General exercised the supreme authority: De Witt was the soul of their deliberations, and he managed, especially the foreign relations of the country, with great ability. He negotiated the peace with Cromwell in 1654, by a secret article of which it was agreed that no member of the House of Orange should be made stadtholder or high admiral. After the restoration of Charles II., De Witt dreading the family connexion between him and young William, sought the alliance of France in 1664. A war broke out between England and the United Provinces, which was at first favourable to the English, but De Witt, by his firmness and sagacity, repaired the losses of his countrymen; and while negotiations for peace were pending, he hastened their conclusion by sending an armament under Ruyter, which entered the Thames and burnt some of the English shipping in the Medway. This was followed by the peace of Breda, July, 1667. The encroaching ambition of Louis XIV., who aimed at taking possession of the Spanish Netherlands, now excited the alarm of De Witt, who hastened to form a triple alliance with England and Sweden, in order to guarantee the possessions of Spain.

In his anxiety to secure his country against the approach of the French, he caused the treaty to be ratified by the States General at once, instead of first referring it, according to the provisions of the Federal Act, to the acceptance of the various provinces separately. This was a cause of violent obloquy against De Witt. While thus occupied with the foreign relations, he did not forego his plans concerning the internal policy of his country and the permanent exclusion of the Orange family from power. In 1667 the states of Holland, at his suggestion, passed 'a perpetual edict,' abolishing for ever the office of stadtholder. De Witt at the same time introduced the greatest order and economy into the finances of the province of Holland. But all De Witt's calculations, both foreign and domestic, were baffled by the intrigues with which Louis XIV. contrived in 1672 not only to detach Charles II. from the Dutch alliance, but to engage him in a counter-alliance with himself against Holland. The French armies now suddenly invaded the United Provinces, Louis XIV. entered Utrecht, and his troops were within a few miles of Amsterdam. There appears to have been great neglect on the part of the officers, civil and military, of the United Provinces, in not having taken measures for resistance, and especially in not having placed their fortresses in a state of defence; and the blame was chiefly thrown upon De Witt. In this emergency, William, the young prince of Orange, was called to the command of the forces, both by land and sea, but this did not satisfy the popular clamour. Cornelius de Witt, John's brother, who had filled several important stations, both civil and military, was accused, evidently through mere malignity, of having plotted against the life of William of Orange, was thrown into prison at the Hague, and tortured; but as he could not be convicted of the charge, was sentenced to banishment. His brother John, whose life had been already attempted by assassins, resigned his office, and went to the Hague in his carriage to receive his brother as he came out of prison. A popular tumult ensued, the furious mob forced its way into the prison, and murdered both brothers with circumstances of the greatest atrocity. Such was the end of this distinguished statesman, whose private character and simplicity were as exemplary as his abilities were high. He wrote his *Memoirs*, which were published in his lifetime, and in which there is much information on the political and financial condition of Holland at the time. (Cerisier, *Histoire des Provinces Unies*; Sir William Temple, *Observations on the United Provinces*; the *Netherland Historian*, 8vo., Amsterdam, 1675, &c.)

DEXA'MINE, a genus of amphipodous crustaceans established by Dr. Leach.

Generic character.—*Antennæ* three jointed, the last segment composed of a number of minute joints; first segment shorter than the second; *upper antennæ* longest. *Eyes* oblong, not prominent, inserted behind the superior antennæ. *Legs* fourteen; first and second pairs monodactyle, with a small compressed hand; other pairs furnished with simple claws. *Tail*, on each side, with three double styles; above, with one small style on each side. *Body*, (including the head) twelve jointed. (Leach.)

Example. *Dexamine spinosa*. Body shining, the ninth, tenth, eleventh, and twelfth segments produced into a spine; front produced and bent downwards between the antennæ. The first joint of the upper antennæ beneath towards their tips, have a little spine-like process. Length three-quarters of an inch. (Leach.)

Locality.—Dr. Leach says that it is very common on the southern coasts of England, and is often taken by the shore-net, or beneath stones amongst the rocks at low tide. The legs, he observes, are easily broken, which will account for Montagu's having described and figured it (Cancer, *Gammarus spinosus*) without the monodactyle hands.

DEXIA'RIÆ, a family of Dipterous insects of the section Creophilæ. This family, established by M. Robineau Desvoidy, is composed chiefly of Meigen's genus *Dexia*. The species may be distinguished from those of neighbouring groups by the greater length of their legs: the body is generally elongated and cylindrical, but sometimes thick, depressed, or rounded. The fore part of the head is, in most of the species, furnished with a ridge situated between the deep grooves in which the antennæ are placed: the antennæ are rather short, and the stylet is generally plumose: the eyes are separated in both sexes, and the males are usually larger than the females. These flies are of in-

offensive habits: they are usually seen on flowers, the juices of which afford them nourishment.

The chief characters of the genera contained in the Dexiariæ are thrown into a tabular form by M. Macquart, in the following manner:—

Proboscis long. Genus 1. PROSENA. *St. Fargeau.*

Proboscis short.

Body cylindrical.

First posterior cellule of the wings closed.

Second and third joints of the antennæ of equal length.

Genus 2. ZEUXIA. *Meigen.*

Third joint of the antennæ longer than the second.

Genus 3. DINERA. *Desvoidy.*

First posterior cellule of the wings open.

Antennæ not extending to the epistoma.

Genus 4. DEXIA. *Meigen.*

Antennæ extending to the epistoma. Legs very long.

Genus 5. SCOTIPTERA. *Macquart.*

Body tolerably broad, depressed.

Fore part of the head arched (colours brilliant).

Genus 6. RUTILA. *Desvoidy.*

Fore part of the head flat (colours, black or yellow).

Stylet of the antennæ naked.

Genus 7. GYMNSTYLA. *Macquart.*

Stylet of the antennæ covered with fine hairs.

Genus 8. OMALOGASTER. *Macquart.*

Of the genus *Prosenæ*, Macquart describes only two species, one of which inhabits Europe, and the other is from Brazil.

Of the genus *Zeuxia* but one species is known.

The genus *Dinera* contains five species, one of which inhabits Brazil, and the others are found in various parts of Europe.

The genus *Dexia* contains twelve species, almost all of which are European.

The genus *Scotiptera* contains two species; they are of considerable size, and inhabit Brazil.

Rutila.—The species of this genus appear to be confined to New Holland: they are generally of large size.

The genus *Gymnostyla* contains three species, two of which are from Brazil, and the third is from Surinam.

The last genus, *Omalogaster*, contains four species, all of which are inhabitants of Europe.

DEXTRINE, a name which has been given, but probably without sufficient cause, to a soluble portion of starch. [STARCH.]

DEY. The origin of the word dey is uncertain. Some have derived it from the Turkish *dâi*, 'a maternal uncle,' and have supposed that this designation was given to the chiefs of the states of Barbary to express their almost paternal authority in the Ottoman empire, and the high esteem in which they were held by the Porte. The name is at all events of more antient date than the Ottoman dominion in northern Africa, since we find it used as early as the end of the eleventh century as the title of the emissaries of the Assassins or Ismaelites. The dignity of dey in the states of Tunis, Tripoli, and Algiers, is not hereditary: on the death of a dey, his successor is chosen from among the highest civil and military authorities, with the concurrence of the Turkish troops stationed in each of the three states. He must be of a certain age and experience, and of acknowledged valour: formerly he was also required to be a Turk, and to have performed a pilgrimage to Mecca; but to this rule there have been many exceptions. On the election of a new dey, the mufti or high-priest of the state reminds him publicly of the duties of the office; and the sultan recognises his election by sending him a robe of honour and (since the beginning of the last century) by conferring the title of pasha upon him. Properly, the deys are vassals of the Porte; but greater privileges are conceded to them than to the governors of any other external province of the Ottoman empire, and in their conduct towards the Porte they have shown so much independence, that their allegiance to the grand seignior is almost nominal. In his own state the dominion of each dey is perfectly free from any control on the part of the Porte. He is elected for life; but the Porte pretends to reserve to itself the right of deposing him if he does not give satisfaction. In his administration the dey is assisted by a diwan, or privy council: but he frequently sets the advice of that body at defiance, and rules with despotic power. In the choice of a

new dey much depends on the inclination of the army; and the election is seldom accomplished without bloodshed. The troops are the principal supporters of the dey; and if they are not paid punctually, or if any measure of the government gives them offence, they revolt, and the dey often loses both his throne and his life.

At Tunis we hear of an elective dey since about the year 1574, when Khâlif was invested with that dignity. Tripoli came into the possession of the Turks about 1551. It was till the end of the sixteenth century governed by pashas or lieutenants appointed by the Porte: from the year 1600 a line of elective deys commenced, the first of whom was Mohammed Beg, a Greek renegado. Algiers was subject to the Ottomans from 1516, and it continued to be governed by pashas sent from Constantinople till 1625. In the latter year a revolution ensued, which terminated, in 1628 in the recognition by the Porte of the first elected dey of Algiers, Haji Mohammed Aga. An officer appointed by the Porte, and bearing the title of pasha, continued to be sent by the grand seignior, in order to keep a watchful eye on the proceedings of the dey: but this system gave rise to constant jealousies between the two chiefs, and from 1710 both appointments became united, inasmuch as the Porte granted the rank of pasha to the dey himself, thus renouncing every right of interfering with the internal policy of the state. A similar arrangement was about the same time made in the state of Tripoli. [ALGIERS, TRIPOLI, TUNIS.]

DHALAC or DAHALAC, an island in the Red Sea, situate in 15° 53' 50" N. lat., and 40° 40' 30" E. long. Its extent from north-west to south-east is about thirty-five, and its breadth eighteen miles. It is the largest island in the Red Sea. It is low, and its surface level, being formed of coralline rocks covered with sand, but destitute of all herbage during the summer heat, except a small quantity of bent-grass just sufficient to feed the few antelopes and goats that are on the island. In many places there are large plantations of acacia trees, but they seldom attain above eight feet in height. There are no springs, and the rain water is preserved in cisterns. Bruce says there were 370 of them; Salt heard of 316, but it seems that their number is much smaller, though considerable, more than 120 having been seen by the officers of the Benares, during their late survey of the Red Sea. There are also some tanks. This island contains two harbours for small vessels, Dhalac el Kibeer and Dobeelow. No kind of agriculture is carried on. According to Bruce, one-half of the male population of the island are always employed in work on the opposite shores of Arabia, and by their labour furnish their families with dhurra and other provisions; when their time is expired they are relieved by the other half. They are good seamen and fishermen. Very elegant baskets are made of the leaves of the doum-tree, and sent to Loheiba and Jidda. The island contains twelve villages, of from 50 to 100 houses each. (Bruce; Lord Valentia; Welsted in the *London Geogr. Journal*, vol. v.)

DHAR, an antient and formerly a very extensive city in the province of Malwa, in 22° 35' N. lat., and 75° 24' E. long. It covers a space three-quarters of a mile long, and half a mile broad, the whole surrounded by a mud wall thirty feet high, fortified with towers at intervals. The pettah or fort is detached from the city and stands on a rising ground. Dhar at one period covered a much greater extent of ground, and contained at least 20,000 houses; in 1820 they did not amount to one-fourth that number, but the town has somewhat increased since that time. The district in possession of the Dhar rajah comprehends about 400 square miles, and contains 179 villages, and about 40,000 inhabitants. When the English entered upon the occupation of Malwa in 1817, the whole revenue of the Dhar rajah, then a minor, was only 35,000 rupees, but in the course of a few years it was made to exceed 600,000. The most important article of cultivation is opium, but the soil is capable of yielding every kind of tropical production. A few of the villages are inhabited by Bheels; of the remaining population fifteen-sixteenths are Hindus, and the other sixteenth Mohammedans.

DIABETES, the discharge of a preternatural quantity of urine, the chemical composition of which is also essentially changed. In this disease the urine is not only unusually large in quantity, but it is either altogether destitute of several of its constituent principles, or it contains them only in very minute proportions, while it acquires a new ingredient, a quantity of sugar, which imparts to it a sweet

taste. Medical writers are not agreed whether the impregnation of the urine with a sufficient quantity of saccharine matter to render it sweet to the taste be absolutely essential to the disease; it is therefore usually divided into two species, namely, *diabetes insipidus*, when there is discharged a preternatural quantity of urine which is perfectly insipid, and *diabetes mellitus*, when the unusual quantity of urine which is voided is sweet to the taste.

The discharge of a larger quantity of urine than natural, unaltered in its chemical constitution, may arise from numerous causes of a temporary nature, scarcely deserving the name of a disease, and certainly not forming a disease of a specific character. The term diabetes should therefore be restricted to that specific disease in which the secretion of urine is preternaturally increased, and its chemical composition at the same time essentially changed.

In diabetes, properly so called, the urine is generally so clear that it appears at first sight to be entirely without colour; but viewed in a certain light, it is seen to be slightly tinged with a yellowish green, or it is of a pale straw colour. Examined by the taste, it is almost invariably found to be more or less sweet; and when chemically analyzed, it is ascertained to contain, usually in considerable quantity, a saccharine matter, which is exactly of the nature of common sugar. Its odour likewise is peculiar; it is commonly compared to the faint odour of violets, or to that of sweet whey or milk. Its specific gravity commonly varies from 1,025 to 1,052. The principle peculiar to healthy urine, *urea*, is generally very much diminished in quantity, though the best chemists have never observed it to be altogether absent. There is, however, little or no lithic acid; it commonly contains the usual saline ingredients, but diminished in quantity; blood itself is sometimes, though very rarely, found in it; it far more frequently contains a considerable portion of one ingredient of the blood, albumen; though the albumen, when it exists in the urine, is in the state in which it is found in chyle rather than in blood. From a table given by Dr. Henry, it appears that ten pounds of diabetic urine, at the average specific gravity of 1,040, yields upwards of a pound and a quarter of solid extract.

The quantity of urine voided in this disease is sometimes enormous. In one case on record, it amounted to the prodigious quantity of 52 pounds in the 24 hours; but instances are by no means uncommon in which the quantity amounts to from 25 to 35 pounds every 24 hours for weeks or even months together. Although one of the most constant constitutional symptoms attendant on this disease is inordinate thirst, yet the urine daily voided almost always exceeds the quantity of liquids drank, and sometimes the whole of both solids and liquids; and even occasionally, as is stated, to have been nearly double the quantity of the whole ingesta. Where can this quantity come from? Some physiologists think that the very solids of the body are melted down and carried off by the urine, whence, as they suppose, the progressive emaciation, notwithstanding the quantity of food and drink consumed; others with more reason suppose that the supply of fluid is obtained by the absorption of moisture from the air by the respiratory and cutaneous surfaces.

The diabetes commonly comes on slowly and almost imperceptibly, at least without any such disorder of the general health as to attract particular notice. It therefore sometimes exists a considerable time before it becomes known; and the change in the quality of the urine is at length discovered by accident; for its quantity may not at first be very much increased, or if increased to such a degree as to attract notice, the circumstance is usually attributed to some temporary cause. At length, however, the constitution manifestly suffers; the strength and vigour fail, the patient feels languid and indisposed to make any physical exertion, the mouth is dry, the tongue clammy; there is unusual thirst; a slight degree of fever is set up, indicated by alternate chills and heats; but the most remarkable circumstance is a change in the condition of the skin, which becomes dry, harsh, and sometimes even furfuraceous, or apt to peel off in scales. The thirst now increases to such a degree as to be evidently morbid; this is often, though not always, accompanied with voracious appetite; and the quantity of urine discharged not only decidedly but steadily increases. If the observation of these circumstances should lead to the examination of the urine, it is found to be sweet to the taste and of a light green or pale yellow colour. The patient meantime is

commonly observed to have lost flesh, and is troubled with a sense of heat and pain in the region of the stomach, with aching in the back and loins, and uneasy sensations in the course of the urinary passages. The bowels are usually costive, the breathing short and oppressed, with a dry tickling cough, and the pulse is commonly frequent. As the disease advances, all these symptoms increase in intensity; the tongue becomes either loaded with a dark-coloured fur, or unnaturally clean and of a dark or purplish red colour; the thirst is more urgent; the appetite, formerly voracious, is now perhaps abolished or depraved; the bowels are more constipated; the skin more harsh and scaly; while the urine, increasing in quantity, becomes still more altered in quality. At length there come on headache, giddiness, occasional loss of vision, impaired memory, and diminished mental energy. The debility and emaciation steadily increasing, the patient sinks with many of the symptoms of hectic fever, or is suddenly cut off by consumption, dropsy, apoplexy, or some other incurable disease established in some vital organ.

From the preceding account it appears that this disease is generally of a chronic character; but it sometimes attacks in an acute form, the marked symptoms of the malady coming on suddenly in a previous state of apparent health, and proving fatal in a few days. This however is very rare. It seldom runs its course under some months, and it sometimes lasts several years. It frequently disappears for a while, especially under proper treatment, and then recurs after the lapse of a few months or years; so that the relief obtained is commonly only temporary, the disease resuming all its severity from a slight exposure to its exciting causes, or from any considerable deviation from the proper diet and regimen. Hence it is perhaps the prevalent opinion among physicians that it is absolutely incurable. Dr. Cullen says, 'In all the instances of this disease which I have myself seen, and in several others of which I have been informed, no cure of it has ever been made, though many instances of it have occurred, and in most of them the remedies recommended by authors have been diligently employed;' he adds, however, 'from the testimony of several authors, I believe the disease has been cured.' There cannot be a question that by appropriate remedies and great and persevering care on the part of the patient, it is capable of being very much relieved, and even of being altogether suspended for an indefinite number of years. The evidence of this is indubitable; but it is more doubtful whether it can be permanently and radically cured. Much of course will depend on the constitution and habits of the patient, and if any other disease be present, on the kind of malady with which it is complicated. It can never be considered as cured until the quality as well as the quantity of the urine is restored to a natural state.

How long the powers of life may be capable of sustaining such an abstraction of the nutritive fluid as is implied in the constant secretion of such an enormous quantity of urine as is commonly formed from the blood in this disease we do not know, because diabetes never consists in the disordered action of the kidney alone; it is seldom, perhaps never, the only serious disease present. The skin is invariably in a diseased state; the lungs are never perfectly sound; some of the most experienced and observant physicians state that they have never met with a case in which there has not been manifest a greater or less degree of disease of the lungs. All writers on the subject record its frequent complication with and termination in consumption; and it is rare indeed that the indications of disease in the digestive mucous surfaces and in the liver are absent.

An inspection of the organs after death which has been made with great care does not throw so much light on the seat and nature of diabetes as might have been expected. In several cases in which the symptoms were present in a very intense degree during life, no appearance of change of structure in the urinary organs could be detected after death. In general however the kidneys are larger than natural; more turgid with blood; more flaccid; softer, and more easily torn. Sometimes, though rarely, they are found in the contrary condition, smaller and harder than natural, and their membranous envelope and their cortical substance are of a cartilaginous firmness and density. Several observers have recorded the remarkable fact, that the organic nerves which supply the kidneys are greatly enlarged in size. The ureters are commonly dilated, and the urinary

bladder is often thickened. It is obvious that these morbid states of the kidneys may be the effects of the disease, and not the causes of it. Next to the kidneys, the organs most commonly found in a state of disease are the mesenteric glands, which are enlarged and hardened. The absorbent glands in general are occasionally enlarged, softened, and more vascular than natural; the thoracic duct is sometimes dilated, and the lungs are constantly found studded with tubercles in all their stages of disease. Though the functions of the stomach, intestines, and liver are so often disordered during life, yet it is comparatively rare that any kind or degree of organic change is discoverable in these organs after death. There is reason to believe that during life the blood is in a morbid state, for when abstracted in the progress of the disease, the crassamentum is found loose, dark, containing a smaller portion of fibrin than natural, and the serum is of a whitish colour; and when examined after death, the blood is found to be more black and more fluid than natural, and to contain a quantity of chyle imperfectly mixed with it.

The true and invariable antecedents of diabetes, or its proper exciting causes, are still involved in obscurity. It has been observed to come on after exposure to several morbid agents, as the long-continued application of cold and moisture, especially after the body had been previously over-heated, implying a sudden check to the perspiration, and a corresponding determination of blood from the skin to the internal organs; exhaustion arising from excessive evacuations, or excessive fatigue, bodily or mental; in short, whatever greatly and suddenly depresses the powers of life: but such causes are applied in all their intensity to the human body many thousands of times for one in which they produce a case of diabetes. They can therefore only concur with some other cause to produce the malady. What that proximate cause is, is wholly unknown. It would seem however to be dependent on a constitutional, that is, an organic, conformation of some organ, or some system of organs; for there is decided evidence that it is an hereditary disease. In one instance on record, seven descendants of a diabetic patient died of the malady; and Dr. Prout states that he has observed it to descend from the parent to the offspring in four instances.

Whatever doubt may be raised about the perfect curability of diabetes, there can be none respecting the decided control which a judicious plan of treatment is capable of exerting over its progress. As the very seat of the disease is unknown, and much more the specific morbid action upon which it depends, it is obvious that no local remedy, applied with a view to produce any specific effect, can be employed with the least chance of success.

It has been stated that the nutritive fluid, the blood, is in a morbid condition, and the circulation itself is deranged. There are unequal determinations of blood to different parts of the system, in consequence of which some organs are deprived of their due proportion of nutrient matter, and others are oppressed by an overwhelming load of it. One of the most constant results of this change in the quality and distribution of the blood, is the excitement of fever, which, as has been stated, is among the very first of the signs by which the presence of this disease is denoted. General blood-letting is the most efficient remedy we possess in directly altering the constitution and the distribution of the blood, by altering the proportions of its constituent elements, and the degree of stimulus afforded to the heart and the capillary arteries. In the early or acute stage of the disease, when febrile symptoms are present, when there is perhaps severe pain in some organ, attended with a sense of heat, and when the pulse is frequent, full, and sharp, bleeding from the arm to the extent of subduing these symptoms and removing the febrile state, is a most efficient remedy, and highly conducive to the success of other remedies. The quality of the blood is found on examination greatly to improve under the judicious repetition and employment of this remedy, the proportion of fibrin increasing, and even the quantity of urea and of saline ingredients also increasing. Even in a more advanced stage of the disease, when the disordered circulation of the blood is rather local than general, when there is evidence of congestion or inflammation of the liver, and still more of the kidneys, cupping over the seat of the disease, and repeated according to the persistence of the symptoms, is both a safe and an effectual remedy. But when the pulse is rapid and weak, the emaciation considerable, and the powers of life decidedly

impaired, blood-letting, either general or topical, can accomplish no rational indication, but must co-operate with the malady to hasten death.

There are few diseases in which the proper regulation of the diet is of such vital importance. As far as it is possible, by a collection and comparison of the morbid phenomena, to judge of the seat of the disease, it would seem to be principally in the digestive and assimilative organs. The stomach is at once irritable and weak. It is in a state of almost constant craving for food, yet its power of digestion is feeble. This is precisely the case in which it is of the last importance to attend strictly both to the quality and the quantity of the aliment. Vegetable matters, more especially sweet and acid vegetables, or those which contain in the greatest proportion the elements of sugar, might well be supposed *a priori* to be bad, and experience shows that they are in the highest degree deleterious. Cases are on record in which, when the patient was in a fair way of recovery, and even when the disease was altogether suspended, the partaking of such vegetables in moderate quantity at a single meal has brought back all the symptoms. Animal food should form the main portion of the diet. Books have been written to show that it should constitute the sole diet; but it never can constitute the sole diet, for mortal resolution cannot long persist in the exclusive use of it; and if it could, the practice would defeat its own object, and still farther weaken the already enfeebled digestive organs. Physiology has demonstrated that life cannot be sustained by one kind of food alone, however nutritious, and that nothing is more conducive to the easy performance of the process of digestion than a due mixture of different kinds of aliment. In the present case experience has fully shown that all the curative effect which can be obtained from what is called the animal regimen, is accomplished by making animal matter the principal part of the diet, and combining with this a small proportion of the farinaceous vegetables. Animal food need not be taken oftener than twice a day, and of all kinds of animal food, beef-steaks or mutton-chops underdone and plainly cooked are the best. The quantity is second in importance only to the quality. The meals should not be at greater distances than five or six hours apart, and any solid food taken oftener than every three hours, however it may for the moment allay painful sensations, operates unfavourably on the progress of the disease. The best drinks are distilled-water, lime-water, alum-whey, and the Bristol hot-well and Bath waters. The latter especially tend powerfully to assuage the thirst; but moderation in the use of liquids is as indispensable as in that of solids, and unless the patient resolutely co-operate with the physician in controlling his inordinate desire for food and drink, no plan of treatment that can be devised will succeed.

The bowels, which are generally costive, require to be kept in a lax state; and even a decidedly purgative course, steadily persevered in, has tended, on obvious principles, greatly to lessen the urinary discharge. The best purgatives are rhubarb combined with senna, and the phosphate of soda; and sulphur forms a very excellent laxative.

Next to the condition of the alimentary canal the state of the skin requires attention, which is often permanently improved, with a proportionate improvement in all the symptoms of the disease, by the persevering and judicious employment of the vapour bath, the hot-air bath, the sulphur bath, the vigorous use of the flesh-brush, and warm flannel clothing, always in immediate contact with the surface of the skin.

As a part of the regimen, regular daily vigorous exercise in pure air is of great importance.

In addition to all this, numerous medicines have been employed with a view of acting directly on the secretion of the urine, as astringents, tonics, and sedatives, some of which experience has shown to be possessed of very considerable power, more especially opium, camphor, ammonia, the carbonate of iron, the mineral acids, &c. The judicious selection and administration of these powerful agents, according to the peculiar circumstances of the individual case, in combination with the general plan of treatment which has been stated, will tend greatly to mitigate the urgent symptoms, and to increase the chance of a permanent cure.

DIACAUSTIC. [REFRACTION; OPTICS.]

DIA'COPE, a genus of fishes of the section Acanthopterygii, and family Percidæ, and belonging to that section of the family, in which the species have less than seven branchiostegous rays, and an interrupted lateral line.

This genus is allied to *Serranus*, but may be distinguished by there being a notch or emargination in the lower part of the preoperculum, into which is fitted a projecting tubercle.

Many large and beautiful species of this genus inhabit the Indian seas. *Diacope octolineata*, a very beautiful species, caught off the coast of the Mauritius, is of a brilliant reddish yellow colour, shaded into white on the belly, and is adorned with four longitudinal blue stripes on each side of the body; these stripes are margined with black. It is about ten inches in length.

Some of the species are known to have attained the length of three feet and upwards.

DIADELPHIA, the seventeenth class in the Linnæan system of arranging plants. Strictly speaking, it ought to contain no genera but those which have their stamens united into two equal or unequal parcels; but as it consists principally of leguminous genera it is customary to place in it all the papilionaceous plants which have united stamens, whether in one parcel or two. This and similar plans render the Linnæan system more natural, but destroy its use as an artificial guide to the determination of the name of a plant.

DIADEMA (Zoology). [CIRRIPEDA, vol. vii. p. 210.]

DIADUMENIANUS, **MARCUS OPELIUS ANTONINUS**, was the son of Macrinus, who was proclaimed emperor by the soldiers after the murder of Caracalla, A.D. 217. After his father's elevation, Diadumenianus, who was then at Antioch, was proclaimed Cæsar by the soldiers, and confirmed by the senate at Rome. He was not quite ten years of age, but is said to have been very handsome and graceful in his person. The reign of Macrinus lasted only fourteen months; a military insurrection, excited by Mæsa, the aunt of Caracalla, who wished to put on the throne her grandson Bassianus, also called Heliogabalus, led to the overthrow of Macrinus, who was defeated near Antioch, and afterwards made prisoner, but killed himself. Diadumenianus, who had escaped from Antioch, was also seized and put to death, A.D. 218. He has been numbered among the emperors, because his father in the latter days of his reign is said to have proclaimed him Augustus and his colleague in the empire. (Lampridius in *Historia Augusta*; Dion, *Epitome*, B. 78.)

Coin of Diadumenianus.

British Museum. Actual Size. Copper. Weight 345½ grains

DIAGONAL, a line drawn from corner to corner any line drawn from point to point of a figure, which is not part of its boundary, provided the two extreme points be in the intersection of boundary lines.

DIAGONAL SCALE. Equidistant parallel lines cut all lines drawn across them into equal parts. Consequently a set of equidistant parallels laid down upon a ruler, with oblique lines of various lengths drawn across them, give with the compasses, the means of immediately taking off various proportions of those lines. But the common diagonal scale is as follows, and facilitates the laying down of

the hundredths of units in a scale of equal parts. A description of its use will immediately suggest the principle of it to any one slightly acquainted with geometry. *AB* is the unit of the scale (usually a quarter of an inch): the diagonal scale professes to determine the hundredth part of this, or the four-hundredth of an inch, and may perhaps, with care, be depended on within the two-hundredth of an inch. By taking off various lines, and writing their numerical designations opposite, we may show the use and meaning of the construction.

$$\begin{array}{llll} ab = 1.00 & ae = 1.21 & lh = 1.22 & mz = 1.96 \\ ac = 1.01 & lf = 1.02 & lk = 1.52 & qv = 1.37 \\ ad = 1.11 & lg = 1.12 & xy = 1.54 & qw = 1.67 \end{array}$$

DIA'GORAS OF MELOS, known also by the name of the Atheist, flourished, according to Suidasin, the 78th Olympiad, 468—5 B.C. Mr. Clinton has adopted this date; but Scaliger (in Euseb. Chron. p. 101) placed him considerably later, fixing his flight from Athens in the year 415 B.C.; and he has been generally followed. The date which Mr. Clinton has taken is the more probable. The precise determination however of the time of Diagoras is not of much importance, as he is only known for his open denial of the existence of gods, and he cannot be said to have any part in the history of Greek philosophy.

Diagoras is said to have broached atheism on seeing a man who had stolen one of his writings and published it as his own go unpunished for the crime. (Sext. Empir. *adv. Math.* p. 318.) On account of this atheism it is generally said that the Athenians put a price upon his head, offering one talent to any one who should kill him, and two to any one who should bring him alive; though Suidas, Athenagoras and Tatian attribute the indignation of the Athenians, and the consequent flight of Diagoras, to his having divulged the nature of some of their mysteries. It is not impossible however that this should have been one of the overt acts by which his character for atheism was established; in which case the two accounts, which seem to differ, would really coincide. He is said to have been bought as a slave by Democritus, and also to have met his death by shipwreck. (Athen. xiii. p. 611, B.) Aristophanes in his play of the Clouds, one object of which was to raise a religious outcry against Socrates, has maliciously fastened on him the odious name of the Melian. (*Clouds*, 830.)

Ælian (*Var. Hist.* ii. 23) says that Diagoras assisted Nicodorus in drawing up the laws of the Mantineans. Diagoras was also a lyric poet, though some, apparently without sufficient grounds, have attempted to separate the lyric poet from the atheist. (Bayle's *Dictionary*; Fabricii, *Bibliotheca Græca*, ed. Harles, vol. ii. pp. 119 and 655.)

DIAGRAM, a mathematical figure of any kind.

DIAL, an instrument for determining the hour of the day from the shadow of a point or line upon a graduated surface. The shadow may be that formed by the light of the sun or moon, and either direct or reflected. The dial, when the sun is used, is called a sun-dial; and when the moon, a moon-dial. The latter kind, as well as those in which the light is reflected, are mere objects of scientific curiosity, and no further notice will be given of them in this work; but the history and structure of the sun-dial will be found under **GNOMON**, **HOURLINE**, and **SUN-DIAL**.

DIALECT (διάλεκτος, διαλέγεσθαι, *to converse*), an appellation given to a language when spoken of in contradistinction to some other language which it resembles in its general features, though differing from it more or less in the details. Almost all the languages which we are acquainted with may be arranged in distinct classes or families, and the relationship subsisting between the members is, generally speaking, pretty obvious. Sometimes the parent language from which they are all descended is still extant, and in that case it is frequently easy to trace the variations in orthography, inflexion, and conjugation from the parent stock, and to determine the principles which governed these changes. These inquiries, whenever they can be successfully prosecuted, are of the greatest importance, as well to the critical historian as to the philologist; for the language of a people points at once to their mental characteristics and the external changes to which they have from time to time been exposed. Thus the Dorian dialect of the Greek language, in the broadness and harshness of its vowel sounds, corresponds to the grave and austere character of the Dorian people: and whenever a warlike race has taken up its abode among a peaceful agricultural

population, traces of this mixture of population are always found in the language, in which the military and political terms are mostly peculiar to the language of the conquerors, while, for the words referring to farming and domestic economy, the aboriginal language is retained. This is strikingly the case in the Latin and English languages. The two most widely diffused families of languages known to us are the Indian-Gothic and the Semitic; the former includes the Sanscrit, Zend, Armenian, Greek, Latin, Lithuanian, Slavonian, Teutonic, and Celtic dialects, in which the resemblances, though sometimes rather distant, are still more or less perceptible. The Semitic family contains the Hebrew, Syriac, and Arabic tongues, with others less known to modern Orientalists. Many of these primary dialects are divided into several sub-dialects; for instance, the ancient Greek had at least three distinct dialects, the *Æolian*, *Dorian*, and *Ionian*.

The differences in the modes of speaking in England can hardly be called dialectical, in the sense in which the word dialect has been explained: such differences, generally speaking, are nothing more than peculiar words or phrases which the written language has not adopted, but which are not the less on that account genuine members of that Teutonic family of which the written language itself is only a part.

But so far as any of these varieties have been committed to writing, and are admitted by a large portion of the population to be a faithful representation of the language in daily use among them, so far such varieties may not inaptly be called dialects. Such are many of the poems of Burns and parts of the novels of Scott. In ordinary conversation in England, the words 'provincialism' and 'dialect' are often used as synonymous, and as expressing some usage of language which is at variance with the established language of the educated and that of the best writers. It is however only a vulgar mistake to consider such words as 'corruptions' of language, which they very rarely are. As a general rule, such words and phrases and such peculiar pronunciations as characterise nearly every county of England, are of the genuine Teutonic stock; and that language which is now the established language of literature, and which has rejected some of the so-called provincialisms and adopted others, might, under different political circumstances, have contained these elements in a different proportion. If the metropolis of England had been on the Severn, the Humber, or the Tyne, who can say how much the written language might have been affected by this circumstance?

DIALECTICS (*διαλεκτική τέχνη*), the old name for the practical part of logic. The word properly signifies 'the art of conversation,' and its use as a name for the art of reasoning seems to have arisen from the fact, that Zeno the Eleatic, who was the first compiler of a system of logic, was also the first writer of dialogues. It is also to be remembered, that formal argumentation among the Greeks was generally carried on by means of question and answer, and Aristophanes uses the more common word *dialexis* (*διάλεξις*), to signify the logic of the Sophists. There were several systems of logic between Zeno and Plato, as, for instance, those of Protagoras, Polus, Gorgias, Euclid, and Eubulides. Socrates never committed any thing to writing; but if we take the representations given of his mode of reasoning by Plato and Xenophon, so far as they agree, we must look upon him as in some measure the originator of Plato's scientific method of arguing. (See Schleiermacher on the Worth of Socrates as a Philosopher, in the *Transact. of the Berlin Acad.* for 1815, transl. in the *Philolog. Mus.* vol. ii.) Plato considered dialectics as the science of definitions (*Sophist.* 253), and as every definition must include both genus and difference, he found it necessary to invent a theory of abstract ideas as the basis of his dialectics; for the ideas (*ιδέαι*) and the genera (*εἶδη*) were, he considered, related merely as subject and object; and he thought that, without assuming the objective existence of the genera, he could have no real general ideas, and so his definition, and consequently his whole dialectical system, which he believed to be the only available means of finding out the truth, would fall to the ground. (Van Heusde, *Initia Philosoph. Platon.*; Cousin, *Fragmens.*) Aristotle's dialectics were based upon a scale of categories or predication, much the same with those of Archytas; he did not think it necessary to assume any *a priori* abstract notions, but conceived it was sufficient for all logical purposes to generalize after

experience. (Facciolati's *Logica Peripatetica.*) The dialectics of the Stoics appear to have been little more than a system of grammatical rules. For the application of dialectics the reader is referred to the article **LOGIC**; and for the outlines of modern dialectical systems the articles **FICHTE**, **HEGEL**, **KANT**, **LEIBNITZ**, **SCHELLING**, and **SCHLEGEL** may be consulted.

DIALLAGÉ. [SCHILLER SPAR.]

DIAMETER, a word most commonly applied to the line drawn through the centre of a circle, and bounded on both sides by the circumference. But the most general meaning is as follows. Whenever any point is called a centre (meaning centre of figure, see **CENTRE**), any line drawn through the centre is called a diameter. And any point which bisects all lines drawn through it from opposite boundaries is called a centre. Thus the circle, the conic sections, the parallelogram, the sphere, cube, and parallelepiped, all have centres, and, by analogy, *diameters*.

DIAMOND, a crystalline gem, which, on account of its high lustre and extreme hardness, has always been regarded as the most valuable of the precious stones; the former of these qualities arises from its great refractive power, and on account of its hardness its lustre remains undiminished. The diamond usually occurs in imbedded octahedral crystals in alluvial ground, in the East Indies and Brazil, and of late years, it is said, has also been found in the Ural mountains. It is commonly colourless or greyish, but sometimes green, yellow, red, brown, blue, and black; the two last-mentioned colours are the rarest. Its lustre is adamantine; refraction single; transparent, but sometimes rendered opaque by foreign matter; hardness 10, exceeding that of any other, and scratching every other substance; owing to its hardness it can be cut, or rather worn down, only by rubbing one diamond against another, and it is polished by the friction of portions of the gem itself reduced to powder; it is broken without difficulty. The specific gravity of the diamond is 3.52; streak greyish; fracture conchoidal; cleavage parallel to the planes of the regular octahedron, which is its primary form, subject however to numerous varieties, and the faces are frequently curvilinear. When rubbed it phosphorises, and becomes positively electrical, and is therefore a non-conductor of electricity. When heated, without the contact of air, it suffers no change, but if ignited in contact with it, it is totally converted into carbonic acid gas, proving that it is carbon in a state of purity.

For ornamental purposes diamonds are cut into two shapes: namely, *rose diamonds* and *brilliant*s, the former being, for the most part, made out of the octahedral crystals, and the latter from those with curvilinear faces. The weight and consequently the value of diamonds is estimated in carats, each of which is equal to 3.166 grains. In the formation of either a brilliant or a rose diamond so much is cut away that the weight of the polished gem is not more than half that of the rough crystal out of which it was formed.

Newton, considering the fact that transparent bodies which are unflammable refract light nearly in the ratio of their density, while those which are inflammable have refractive powers that are greater than their density, was led to conclude that the diamond, on account of this great refractive power, was 'probably an unctuous substance coagulated.'

In 1695 experiments were made at Florence, which proved the diamond to be dissipated by intense heat in the focus of a burning lens. Several chemists proved that diamonds lost no weight when heated without the contact of air, and on the contrary, that they were dissipated when heated in it; but it was first shown by Lavoisier that carbonic acid was obtained by the combustion of the diamond, and he concluded that it contained carbon, and had great analogy with this combustible body.

These researches were not however sufficient to afford complete proof of the nature of the diamond; but this was accomplished by the succeeding experiments of Smithson, Tennant, Guyton Morveau, Allen and Pepys, and Davy, who all arrived at the same conclusion, which is, that although there exists in many respects so great a difference between the properties of the diamond and charcoal, they are identical in their chemical nature. Thus, whenever, by combustion, 6 parts of charcoal, or an equal weight of diamond, are combined with oxygen, the quantity of oxygen absorbed always amounts to 16 parts, and the result of their combustion is 22 parts of carbonic acid.

DIAMOND. The pencil diamond used by glaziers to cut glass with is a small fractured piece of diamond. The part of the diamond used for cutting is of a trapezoidal shape, weighing about the 60th part of a carat, and is set in a wooden handle, which consists of a rounded piece of rose-wood flattened at the two sides to fit between the sides of the fore and middle fingers.

Two pencil diamonds are now in use, the old and the new or patent pencil. The old diamond is merely set fast in a conical shoulder. A difficulty is always experienced in cutting glass with this sort of pencil, owing to the uncertainty of placing it at once at the proper angle with the glass, so as to make it cut and not scratch. The patent diamond, of recent invention, overcomes this difficulty. The form is represented in the annexed figure. The peculiarity consists in the diamond being set in a parallelopiped shoulder, *b, b*, the right angle of the lower end of which is cut off and forms the correct angle at which the diamond when set will cut the glass. The upper end of the shoulder swivels at *h*, but is stopped from going too far by the screw *a*. The object of this is to prevent the necessity of shifting the handle in the hand when placed against the ruler laid on the glass. The lower end of the shoulder, showing the diamond, is represented at *c*. A large diamond is not so fit for the purpose of cutting glass as a small one. The diamond is usually about the size of an ordinary pin's head, and is set in a nipple of brass or copper. It is an error to suppose that diamonds will not wear out. In the shops of wholesale glaziers, where the diamond is in constant requisition, one of these instruments is worn down in a month or six weeks, so as to require resetting, after which, with the same wear, it usually lasts another month, and then becomes useless. It may be presumed that they travel over some miles of glass before they are worn out. In cutting the glass, care is taken not to press too heavily on the diamond, which is apt to scratch instead of cutting the glass; such heavy pressure also spoils the diamond.

The price of these useful instruments is, for a common pencil 12s. and for a patent pencil 18s.

DIAMOND HARBOUR, in the river Hoogly, about 35 miles in a direct line below Calcutta, is the place at which the large ships employed by the East India Company were accustomed to discharge their outward, and take on board the greater part of their homeward, cargoes, their loading being completed in Saugor Roads. Large warehouses for containing ships' stores have been built here, and an excellent raised road, or causeway, constructed between Diamond Harbour and Calcutta, passes through rice-fields in a state of high cultivation. The station is found to be very unhealthy, especially between July and September, owing, it is supposed, to the great quantity of vegetable matter brought down by the floods and allowed to stagnate upon the low swampy shore.

DIA'NA, a goddess who was worshipped in antient Rome and Italy. It has been already stated [BELLONA] that the only safe authority for defining the attributes of the Roman deities is the etymological origin of the names; and in the same place it was pointed out that each element of nature supplied the Romans with two deities, a male and a female. Thus Dianus and Diana are properly two adjectives, derived from *dies*, 'day,' or, perhaps, originally 'light,' precisely as *quotidianus* from *quotidie*, and in this way they were the appropriate names of the god and goddess of light, the former representing the sun, or greater light, the latter the moon. Dianus, by an easy change, would become Janus, as Diana, we know, was corrupted by the rustic population into Jana in their hymns to the new moon, beginning *Jana novella*.

As the huntsman of Italy preferred the night for his sport—

Manet sub jove frigido
Venator, teneræ conjugis immemor—

Diana, or the moon, naturally became the patroness of the chase, and so of the wood. Again, in her character as goddess of light, her aid was invoked in parturition. In

this latter office she was also called *Lucina*, a term of precisely the same import from *luc*, 'light;' and the identity of the two goddesses is established by the contracted form *Luna*, which, like *Diana*, is the name of the moon.

Diana had a temple on Mount Aventine, and another near Aricia. Indeed her worship belonged strictly to Latium and the plebeians of Rome. [ARTEMIS.]

DIANÆA. [MEDUSA.]

DIA'NCHORA, a genus of fossil conchifers, established by Mr. Sowerby in his 'Mineral Conchology.'

Generic Character.—Shell delicate, adherent, regular, symmetrical, equilateral, subauriculated, inequivalve; one valve hollowed within, convex without; the other flat. Hinge consisting of two distant condyles.

Cuvier (*Règne Animal*) places the genus between *Pachytes* and *Podopsis*, M. De Blainville between *Plagiostoma* and *Podopsis*, and M. Rang between *Pecten* and *Pedum*. M. Deshayes, in his edition of Lamarck, after observing that *Pachytes* had been formed at the expense of *Plagiostoma*, states that his examination of the species had satisfied him of the identity of the genera, and that the same examination instituted with regard to *Dianchora* had convinced him that the characters of the last-named genus were identical with those of *Pachytes* and *Podopsis*. A further inquiry terminated in the conclusion that the so-called genera, *Podopsis*, *Dianchora*, and *Pachytes*, were only *Spondyli*, whose internal lamina had been dissolved, and had left naked the external or conical lamina. [SPONDYLUS.] The subjoined cut will convey to the reader the form of one of the so-called species.

[*Dianchora striata*.]

DIA'NDRIA, the second class in the Linnæan system of arranging plants. It comprehends all genera with flowers having only two stamens, provided the stamens are neither united at their base, nor combined with the style and stigma, nor separated from the pistil.

DIANTHUS, a beautiful genus of Silenaceous Dicotyledonous plants, with a calyx closely covered at the base by two, three, or four, opposite pairs of decussating rigid sharp-pointed bracts. The petals are always more or less lacerated at the end, and in some species are divided into fine capillary segments. There are ten stamens, two styles, and the capsule is one-celled, with numerous black seeds containing a straight embryo. In all cases the leaves are long, narrow, one-ribbed, sharp pointed, and destitute of all lateral reticulated veining.

De Candolle enumerates 113 species, of which some must undoubtedly be reduced to simple varieties. They are found in all the temperate parts of Europe and Asia, from Ireland to the eastern coast of China and Japan; two have been met with in the United States of America, and four at the Cape of Good Hope. Most of them are perennial herbaceous plants with permanent leaves and stems, and hence they ought perhaps to be considered under-shrubs; a few become woody and form genuine bushes.

The most remarkable species are *D. barbatus*, or the Sweet William, a common and very beautiful hardy herbaceous plant, native of the south of Europe; *D. Caryophyllus*, or the Clove Pink, so called from its spicy fragrance; in its wild state a native of France and England, in its cultivated state the parent of the Carnation, Picotee, and Pink of the florists [CARNATION], and *D. Libanotis*, the Syrian Pink, with the most lovely feathered petals; there are however few genera in which the species are so generally deserving of the gardener's care, for we do not know one that is otherwise than beautiful. The species are however seldom seen, in consequence of a difficulty in preserving them in a healthy state in the damp climate of Great Britain.

Although some of the species are indigenous to Great Britain, by far the greatest number are natives of the southern parts of Europe; abounding in Germany, Switzerland, Italy, and along the shores of the Mediterranean, Black and Caspian Seas, inhabiting rocks, mountains, and dry warm stony places most frequently, although occasionally living in sandy and damper places. Of our own wild kinds, *D. Caryophyllus* only occurs upon old crumbling walls, such as those which surround the city of Norwich, others in dry gravelly places or on limestone rocks.

It is therefore obvious that the gardener must pay special attention to this peculiarity, and guard by every means in his power against the access of wet, unless when the plants are in a state of free growth. In the winter, when they are at rest, they bear moisture very impatiently. It is therefore either upon rockwork or in pots housed in winter that the species of *Dianthus* are best preserved: we remember indeed to have seen a plant, either *D. deltoideus* or an allied species, growing by a single stem from a cleft in a hard wall near Bristol, where it had been established many years. The soil in which they are planted should consist of equal quantities of good fresh loam and vegetable mould, to which may be added a little horse dung and sand, the whole to be mixed well, and allowed to remain for a season before being used.

All the species may be propagated either by seeds or by the same processes that are employed for the Carnation and Picotee, namely, by layering or piping. Layering is decidedly the surest method, as the young shoot derives support from the parent plant until it has protruded rootlets of its own for nourishment. In this operation, gardeners generally practise a method technically called tonguing which is simply making a slit with a knife, from a little below the joint, up through its centre, and then carefully pegging the young shoot down as in the common way. Pippings are a sort of cuttings, and will root freely in a melon or cucumber frame, which can often conveniently be applied to this purpose in the end of the season; but as artificial heat is not essential to success, those who have not this convenience may succeed very well with a small hand-glass.

If the pippings are not in a shaded situation, it is necessary to shade them when the sun's rays are powerful; because the rootlets are for some time insufficient to supply the stem with fluid enough to counteract the effects of evaporation. It is the want of due attention to this which causes the result of propagating the *Dianthus* by pippings to be considered uncertain: if shade and moisture are supplied for a sufficiently long time, there is little risk of the pippings not forming young plants.

DIAPA'SON, in music (*διά, through, and παῶν, of all*), the interval of the octave, so called because it includes all admitted musical sounds. It likewise signifies the compass of any voice or instrument; and the French employ it to express what in England is meant by the term *Concert-Pitch*. [CONCERT-PITCH.]

DIAPASON STOP, in an organ. [ORGAN.]

DIAPENSIA'CEÆ, a very small natural order of monopetalous Exogenous plants, formerly mixed with Convolvulaceæ, but in reality more nearly allied to Polemoniaceæ. Only two genera are known; they consist of small depressed half-shrubby species, with the habit of a minute-leaved Phlox. Their calyx grows in a broken whorl; the corolla has an imbricated æstivation with five lobes, and as many stamens growing from its margin in the sinuses; the anthers have a broad connective, and burst transversely. The ovary is three-celled, with a good many ovules growing upon central placentæ. Finally, the embryo lies across the hilum, in the midst of fleshy albumen. No use has hitherto been made of these plants. (See Lindley's *Natural System of Botany*, p. 233.)

DIAPENTE, in Greek music, the interval of the Fifth.

DIAPHANOUS. [TRANSPARENT.]

DIAPHORETICS, or SUDORIFICS, are agents which increase the natural exhalation of the skin, or restore it when suppressed. Nothing better exemplifies the doctrine that remedies are only relative agents than this class of medicines, as their power to produce perspirations depends invariably upon the state of the patient and the circumstances in which he is placed, such as the temperature and humidity of the air by which he is surrounded. Many medicines which cause a flow of perspiration when the patient is kept warm, will produce, when he

is in a cool temperature, an increased action of the kidneys and an augmented secretion of urine.

Their effects as diaphoretics are attempted to be accounted for by reference to two principles; 1, by increasing the action of the cutaneous vessels; 2, by increasing the vascular action of the whole system. Those diaphoretic remedies which seem to act according to the first principle produce their effects either by external application, such as the stimulus of heat, especially as proved by the hot-air bath, or as medicinal substances which enter the circulation and stimulate the cutaneous vessels by contact, such as mercurial preparations, some saline diaphoretics, and, most markedly, sulphur, which is evidently carried undecomposed to the cutaneous vessels and excreted by them; or, lastly, by acting on the surface sympathetically through the medium of the stomach, such as warm drinks, antimonial preparations, &c.

Those diaphoretic agents which seem to act according to the second principle are:—violent muscular exercise, carbonate of ammonia, guaiacum, alcoholic stimulants, &c.

Diaphoretics are in general used to restore the cutaneous discharge when, from the action of cold or wet upon the system, it has been suppressed, and accordingly they are useful in common catarrh, rheumatism, or diarrhœa proceeding from cold. They are likewise of great service in fevers, the restoration of the secretion of the skin, if it be warm and gentle, not cold and clammy, often proving critical, and the precursor of recovery. In many cutaneous diseases diaphoretics are valuable agents, and for this purpose baths, either the natural warm baths or vapour baths, are used; but in such diseases the perspiration produced by exercise, or during a course of training, is decidedly the best diaphoretic. Some forms of indigestion are relieved or cured by causing an increased action of the skin, to effect which exercise is likewise the best agent.

It is worthy of remark, that the profuse and wasting perspirations which accompany the hectic of consumption are frequently more effectually checked by diaphoretics, especially the compound ipecacuan powder, than by any other means. (*Young on Consumption*.)

DIAPHRAGM (*διάφραγμα*), *septum transversum*, *transverse partition*, *midriff*, a circular muscle, placed between the thorax and abdomen, forming a movable partition between these two great cavities. Its borders, which are broad and fleshy, are movable; its central portion, which is tendinous, is fixed and immovable. When not in action, its upper surface, or that towards the thorax, is convex, presents the appearance of an arch, which reaches as high as the fourth rib, and is covered by the pleura, the membrane which lines the cavity of the thorax. Its under surface, or that towards the abdomen, is concave, and is covered by the peritoneum, the membrane which lines the cavity of the abdomen. It is perforated by several apertures, through which important organs pass from the thorax into the abdomen, and from the abdomen into the thorax. In its tendinous portion, between what is called its crura or legs, there is an oval aperture through which the aorta, or great artery of the trunk, passes from the thorax into the abdomen, and the thoracic duct enters from the abdomen into the thorax. A little above this and to the left of it, in the fleshy portion of the diaphragm, is an aperture through which the œsophagus passes in its course from the mouth to the stomach. On the right side of the diaphragm, in its tendinous portion, is a third aperture, through which the inferior vena cava passes from the abdomen to the heart.

The diaphragm is a muscle of extreme complexity in its structure, and, next to the heart, performs the most important function of any muscle in the body. Its most important office is connected with the function of respiration, and it is the principal agent both in enlarging the cavity of the thorax in inspiration, and in diminishing it in expiration. These actions it performs by virtue of the power of alternate contraction and relaxation which it possesses in common with all muscles. When in the state of relaxation, as in expiration, its broad, lateral, movable borders present an expanded arch, the convexity of which reaches, as has been stated, as high as the fourth rib; when in action, as in the state of inspiration, the fibres composing the lateral borders contract, whence this movable partition descends, until, from the form of an arch, it presents a plane surface, increasing the capacity of the thorax by all the space that intervenes between the fourth rib and

the lowest point to which the diaphragm is capable of descending. The fibres then relaxing, the movable borders are pushed up by the contraction of the powerful muscles of the abdomen, until the diaphragm again assumes the form of an arch, diminishing the capacity of the thorax by all the space that intervenes between the lowest point to which it descends and the fourth rib. These alternate actions, which are performed in regular and uninterrupted succession, day and night, during our sleeping and our waking hours, from the moment of birth to that of death, constitute the principal portion of the mechanical part of the function of respiration or breathing, by which air and blood flow to and from the lungs. During these actions the central portion of the diaphragm, on which the heart rests, and to which the pericardium is attached, never moves; so that though the diaphragm is in constant motion, it never disturbs the action of the heart, which it assists in supporting, and the function of the circulation is not disordered by the movements which are indispensable to the function of respiration.

There is a fixed relation between the action of the diaphragm and of the abdominal muscles. When the diaphragm contracts, the abdominal muscles relax; when the abdominal muscles relax, the diaphragm contracts. The diaphragm is the antagonist of the abdominal muscles in inspiration; but it acts in concert with them in vomiting, in the discharge of the contents of the bowels and of the urinary bladder, and in assisting the expulsion of the fœtus in parturition. To produce the respiratory movements, and to assist in the expulsion of the fœces, the urine, and the fœtus, may be considered the natural and regular offices of the diaphragm; but it conduces to the performance of many other actions. It is the principal agent in vomiting, yawning, coughing, laughing, crying, and in hiccup, which may be regarded as its more powerful and irregular actions.

DIARBEKR, more properly **DEY-A'R-BEKR** (the tents or dwellings of Bekr), a town in Al-jezirah (the peninsula), is situated about 38° N. lat. and 40° E. long. It stands at a short distance from the right bank of the Tigris, the intervening space being occupied by gardens. The area of the town is considerable; the walls are lofty and substantial, and surmounted by a castellated parapet. Formerly the town was inhabited by 40,000 families, had extensive manufactures, especially of cotton goods, and carried on a very active commerce with India, through Bagdad, and with Europe through Aleppo. But the fertile plain, 150 miles in length, on which it stands, has in later times been laid waste by the invasion of the Kurds; the commerce with Bagdad is annihilated, and that with Aleppo reduced to insignificance. Still it contains about 8000 families (1500 are Armenian, 85 Catholic, 70 Greek, 50 Jews, and 6300 Turkish), and some manufactures of cotton, silk, and leather, especially morocco. It is the seat of a Jacobite patriarch and a Nestorian archbishop. The Tigris cannot be used as a means of transport so high up as Diarbekr; but rafts of timber are sometimes floated down from the mountains above the town. It is conjectured that the antient town of Constantia stood on the site, or in the neighbourhood, of Diarbekr. (Brant, in *London Geogr. Journal*, vol. vi.)

DIARRHŒA (*διάρροια*), flux, looseness, purging, the frequent discharge from the bowels of more liquid stools than natural. The most obvious and common cause of this disease is the direct application of some stimulating substance to the inner or mucous surface of some portion of the alimentary canal; as articles of food and drink of too stimulating a quality, or, though wholesome in kind, taken in too large a quantity. Undressed or indigestible vegetables, whether acid or sweet, cucumbers, melons, mushrooms, different kinds of salads, fruits, especially plums, stale and decayed vegetables, animal food approaching to the putrescent state, as stale fish, high game, &c., contain matters either not easily digested, or when digested of so stimulating a quality as to irritate the mucous surface of the intestine, and to produce diarrhœa. Water tainted with putrid vegetable or animal matters, or loaded with certain kinds of living or dead animalcules, is no uncommon cause of diarrhœa. When a great mixture of different kinds of food and drink, in large quantities, though wholesome in kind, is taken into the stomach at one meal, it often produces a sudden attack of diarrhœa. Even a draught of cold water, beer, or milk, especially if the individual

be overheated at the time, will often almost immediately occasion the same result. Many medicines and poisons are substances which prove directly and powerfully irritating to the stomach and intestines. The large class of purgative medicines and the poisons called irritants are of this kind. Purgative medicines, given in a certain quantity and at certain intervals ascertained by experience, produce a certain degree of diarrhœa, which the physician purposely excites for the accomplishment of various objects. Given in very large doses, or in ordinary doses when the system is in a state of peculiar irritability, they sometimes occasion an excessive diarrhœa, which continues longer than usual, and so produce that species of diarrhœa which is called hypercatharsis.

In the state of health various fluids are poured into the stomach and alimentary canal for the purpose of dissolving the aliment and assisting in its assimilation. To accomplish the purpose for which they are secreted from the common mass of blood, these fluids must be in certain quantity, and must possess a certain degree of stimulating power. But in various states of the system, from being bland in their sensible properties, and only moderately stimulating in their physiological action, they become greatly increased in quantity, and highly irritating in quality. Of these fluids the principal are the gastric, the intestinal, the pancreatic, and the biliary. The secretion of the gastric juice may be altered in quantity and quality, in consequence of which it may be incapable of properly dissolving the aliment, which therefore may be sent from the stomach into the intestines in an acrid and irritating state, and so produce diarrhœa. The pancreatic juice may also be altered in quantity and quality, and become highly irritating; and the bile is sometimes poured out in greater quantity than usual, and of a more than ordinary acrid quality, and in both ways is a frequent cause of diarrhœa. Moreover, the entire surface of the stomach and intestines is crowded with secreting organs, mucous follicles, from which a quantity of fluid is constantly poured out, constituting the chief portion of the evacuations passed when little or no food has been taken, and which probably also affords the principal part of the matter of the liquid stools that occur in diarrhœa. In many states of the system, and from numerous irritating substances applied to their surfaces, the secretion of these bodies becomes excessive in degree, and highly acrid and irritating in its nature.

The quantity of matter from this source may be indefinitely increased by whatever is capable of occasioning a greater efflux of blood than natural to the mucous surface of the alimentary canal. Hence it may be superinduced by all the other causes of diarrhœa—indigestible food, wholesome food in too large a quantity, disordered states of the digestive fluids, &c., and from increased afflux of fluids from other parts of the system, as from cold applied to the surface of the body and suppressing perspiration, which may determine a greater quantity of fluids to the intestines. Great alternations of temperature will, in many constitutions, produce the same result. Suppressed evacuations, checked menstruation, the retrocession of eruptive diseases, as measles, scarlatina, &c., are often immediately followed by diarrhœa. Even mental emotion is capable of producing it in some irritable and nervous constitutions to a great degree; and when under the influence of such emotions, the slightest excess in food or drink, or the slightest quantity of irritating aliment, will be succeeded by numerous and liquid stools. Irritation in a distant part of the body often induces increased action of the intestines and occasions diarrhœa, as the irritation of the gum in dentition. The mucous surface of the whole alimentary canal is highly sensitive and irritable in infants and children, and food improper in quantity or quality is exceedingly apt to induce diarrhœa in them, and if the irritation in the stomach and intestines from this cause be kept up long, irreparable and fatal disease is sure to be induced. Slight errors in diet on the part of the mother, and even an irritable state of mind, will disorder her milk to such a degree as to produce distressing diarrhœa in her infant. The excitability of the capillary arteries, the mobility of the muscular fibres, and the sensibility of the whole nervous system during the early periods of life, render the young much more susceptible to all the causes of diarrhœa than the adolescent and the adult; and the more tender the age the greater this susceptibility.

By whatever cause diarrhœa may be excited, it is seldom

that the increased discharge of liquid stools from the intestines is the only symptom present. It is commonly preceded by nausea, and in general more or less uneasiness is felt in the stomach and intestines, which sometimes amounts to severe griping pain, often accompanied with flatulence. In severe cases, the abdomen is distended, and even tender to the touch; the nausea passes into vomiting, and the pain, especially around the navel or in the course of the colon, becomes intense, somewhat relieved, perhaps, after each evacuation, but soon returning with undiminished severity. The number of evacuations may vary from three or four to twenty or thirty in the twenty-four hours. Of course the sudden loss of so large a portion of the more fluid part of the blood as is contained in these watery evacuations, deprives the system of a proportionate quantity of stimulating and nutritive matter, and accordingly there is often great prostration of strength, and a striking expression in the countenance and attitude of languor and debility. In slight cases, the pulse is little if at all affected; but when the pain is severe and the discharges copious, the pulse is quickened, and at an advanced stage of the attack is generally small, weak, and much increased in frequency. The tongue is loaded, and in certain forms of the disease is intensely red at the edges and tip, and the papillæ are large, prominent, and of a bright red colour, shining through a thick coat of fur. The urine is generally diminished in quantity. The skin, at first hot, towards the termination of the attack is unusually cold and chilly, and is peculiarly incapable of resisting the influence of a cold and damp atmosphere. Every observant physician must be able to recal instances which have occurred in his practice, in which inflammation of some vital organ was set up, or perhaps the foundation of consumption laid, from the patient having imprudently gone out on a cold and wet day after having taken purgative medicine, or when labouring under diarrhœa spontaneously induced.

The nature of the matters contained in the evacuations varies remarkably, and affords important indications of the seat and state of the disease. Several varieties of the disease have indeed been founded on those appearances, and diarrhœa has accordingly been divided into fæculent, bilious, mucous, serous, chylous, lienteric, &c., but the causes of the disease afford more fixed and determinate characters for its distribution into species. Of these there are commonly enumerated the following:—diarrhœa *crapulosa*, from food improper in quality or quantity; diarrhœa *biliosa*, from bile more abundant or more acrid than natural, as from the heat of summer and autumn, co-operating with errors in diet; diarrhœa *serosa*, from increased vascular action of the mucous surface of the alimentary canal, induced by whatever occasions a preternatural afflux of blood to the mucous surface; diarrhœa *mucosa*, from increased secretion of the mucous follicles, which may be induced by almost any of the ordinary exciting causes of diarrhœa; diarrhœa *lienterica*, the aliment passing in the evacuations almost unaltered, occurring principally in children about the first, and between the first and second dentition, and occasioned by the ordinary exciting causes of diarrhœa.

The duration of this disease must of course be materially influenced by the persistence of the cause that excites it. Its ordinary varieties being generally dependent on temporary causes, are of short duration; but the increased secretion of bile by the liver, and of mucus by the mucous follicles, and the irritation of the intestinal canal from dentition, may be protracted to an indefinite period; and the disease dependent on the excited state of these organs may consequently become chronic, continuing for months together to harass the patient and enfeeble the constitution. In these cases, when a cure is apparently effected, very slight causes are capable of bringing back the disease; and during the period of convalescence the utmost caution is always necessary to avoid errors in diet and any exposure to cold or wet.

The immediate danger from a very severe attack of diarrhœa, or from its passing from the acute into the chronic state, is, that it should terminate in acute inflammation of the bowels (enteritis); or chronic inflammation and ulceration of the bowels (dysentery); or intus-susception (the passing of one convolution of the intestines into another), induced by the increased peristaltic action of the bowels; or enlargement, hardening, and obstruction of the

mesenteric glands, and the consequent wasting of the body (marasmus), one of the most common forms of disease by which the existence of infants and children is cut short.

There are several diseases with which diarrhœa may be confounded, from which it is important that it should be distinguished. From the far more serious malady termed dysentery it is distinguished by the absence of fever, by the absence of blood in the evacuations, and by the absence of the painful, distressing, and ineffectual desire to evacuate the contents of the bowels which is called tenesmus. It is distinguished from cholera by the absence of spasms of the muscles, so constant and distressing in the latter disease, by the slighter degree or the total absence of vomiting, and by the milder character and the much less rapid progress of the entire disease. But the bilious and even the pestilential cholera frequently commence with one or other of the preceding forms of diarrhœa. Life often depends on the clearness and promptitude with which the diagnosis is made between diarrhœa from irritation, constituting the crapulous and bilious forms of the disease, and the diarrhœa from inflammation, which often appears under the serous and mucous forms. The diagnosis is chiefly to be drawn from the marked difference in the constitutional symptoms when the diarrhœa is the consequence of an inflammatory state of the internal surface of the intestines. In this case there is always present a greater or less degree of fever; the skin is hot, or alternately hot and chilly; the pulse is more or less excited, and the strength prostrate. The pain in the bowels is obscure and dull rather than griping, the abdomen is tender on pressure, and it is in this case more especially that the tongue is preternaturally red at the edges and the tip, and that its papillæ are enlarged and red.

Though diarrhœa is often a trifling disease, and even a remedial means adopted by nature to prevent the occurrence of more serious evils, yet the serous and mucous forms of it, more especially when they pass into a chronic state, are apt to terminate in dangerous and fatal maladies, and their management requires great and persevering care. Instances are by no means unfrequent in which the ultimate event proves fatal, in consequence of their neglect, or of the medical treatment and the remedies being injudicious. Indeed the treatment of diarrhœa in general requires much discrimination, for a very trifling form of it is easily converted by mismanagement into a highly dangerous disease. The chief difficulty is to detect the exact nature of the exciting cause, and the exact condition of the excited organ, which alone can guide to the selection of one of two opposite plans of treatment, the administration of purgative or of opiate medicines. If the irritation arise from too large a quantity of stimulating food and drink, abstinence alone is sufficient to effect a cure; but if, notwithstanding the abstinence from food, the disease continue, it is necessary to ascertain whether the irritation be kept up by the retention of irritating matters, or whether the alimentary canal itself be in a preternaturally irritable and excited state. If the former, purgative medicine of some kind or other is indispensable, but the choice of the purgative is by no means a matter of indifference. It should have the power of evacuating the contents of the bowels without irritating the mucous surface. For this purpose castor oil is one of the best medicines; or, if a somewhat stronger purgative be required, infusion of senna with manna. It is often attended with the best effects to combine a few drops of laudanum with the aperient. When the irritating contents of the stomach and intestines are removed, a mild and frequently repeated sedative should be prescribed, one of the best of which consists of two drachms of almond oil with two drachms of mucilage of gum arabic in an ounce of rose or peppermint water, with from five to ten drops (according to the severity of the case) of laudanum or half a dram or more of the tincture of hyoscyamus. If the secretions are disordered, five grains of blue pill or of hydrargyrum cum creta, with the same quantity of the compound powder of ipecacuanha, taken every night, or every other night, at bed-time, with a tea-spoonful of castor oil, containing a few drops of laudanum, the morning following, will soon restore them to a healthy state. Of course the diet should consist only of the mildest alimentary substances; for as long as the alimentary canal continues irritable, food and drink, even of the ordinary stimulating properties, will keep up or re-excite the diarrhœa.

The exciting cause of the biliary variety of diarrhœa is

often inflammation of the liver (hepatitis). When there are present any indications of this, blood-letting, or local bleeding by cupping or leeches, must precede all other remedies; and the abstraction of blood must be repeated at short intervals until the inflammatory state of the liver is removed; then mild mercurials, with mild purgatives, are necessary. This is by no means a variety of diarrhœa which can be cured by opiates. The exhibition of any remedies of this class, which, when judiciously managed, are sometimes highly advantageous, requires peculiar discrimination and skill. In the serous and mucous diarrhœa, when there is present no proper fæculent matter, all this having been previously discharged, it is absurd to give purgatives; such medicines can only still further irritate the over-excited organs. Leeches to the abdomen, the warm bath, demulcents with opiates, the chalk mixture, and the strictest regulation of the diet, are necessary.

The diarrhœa, so easily excited, so constantly present, in infants and young children, requires a peculiarly cautious management. When it is connected with dentition it is pregnant with danger to stop the discharge, or even to restrain it, unless it become excessive, and then it should be moderated, not stopped; and the mildest means should be employed to accomplish this object, which should never be attempted without at the same time paying the strictest attention to the diet, air, and exercise of the child. Death is often produced in infants at this critical period of the infant's life by the exhibition of opiates to stop this discharge. The proper remedies are the choice of the blandest articles of food, the avoidance of over-feeding, two or three grains of hydrargyrum cum creta at night, and the tepid bath.

It would swell this article much beyond our limits to enter into a full account of all the precautions which are necessary on the part of the mother and nurse, as well as of the medical practitioner, in relation to this very important subject. All that is possible is to direct attention to the points of essential importance.

DIARY, from the Latin *Diarium*, which again is from *Dies*, a day. The original and proper meaning of the word *Diarium* among the Romans was the daily allowance made to slaves for their sustenance, as *Menstruum* was their monthly allowance. *Diurnum* was another word for the same thing. [ACTA DIURNA.] In later times however either word came to be used for a note-book, or other register of daily occurrences, which had formerly been called (after the Greek) an ephemeris. It is only in the sense of a daily register that the word diary is used in English; and, naturally enough, it is commonly understood to imply specifically a register of occurrences in which the writer has had a personal share, or which have at least in some sort come under his own observation by having happened in his own time. For instance, although a history of the transactions of a former age, composed in a particular form, might be entitled annals, such a history, however minute, would scarcely in any case receive the name of a diary. A diary is etymologically the same thing with a day-book or journal; the latter word being a modernized form of diurnum, as diary is of the synonymous diarium of the same parentage. The French language has only the form *journal*; the Italian, like the English, has both forms, *diario* from *diarium*, *giornale* from *diurnum*, both ultimately from *dies*.

DIASCHI'SMA, a term employed in antient and in speculative music, but not in practical use among modern musicians. It is the half of a minor semitone or diesis. [DIESIS.]

DIASO'PORA. [POLYPIARIA MEMBRANACEA.]

DIATYPE. [CIVIL ARCHITECTURE, vol. vii., p. 220.]

DIA'STYLIS, a genus of crustaceans established by Mr. Say.

Generic Character.—Four antennæ placed nearly on the same line; the intermediate antennæ bifid, having a peduncle of three joints, the external simple, with the first joint long, and without a scale. External jaw-feet very large, pediform, very much approximated to the front, with the first joint long and compressed, and the others very small, cylindrical, and nearly equal. *Corselet* smooth, of six segments, of which the first, larger than all the others together, is terminated anteriorly by a short, obtuse, triangular rostrum, crenelated on its lateral edges. Six pairs of bifid feet; those of the first pair truncated at the end and shorter than the external jaw-feet; those of the second terminated in a point; those of the third, fourth, and fifth

pairs raised, pointed, without a nail, and terminated by strong hairs. *Abdomen* narrower than the *thorax*, formed of six segments, the two last of which support the natatory feet. *Tail* biarticulated, provided on each side of the first segment with a single bifid style, and on the extremity of the second with a simple cylindrical style.

Example, *Diastylis arenarius*: length one-fifth of an inch. *Locality*, the coasts of Georgia and Florida.

Mr. Say is of opinion that the *Cancer scorpionides* of Montagu, from the English coasts, and the *Cancer Esca* of Gmelin, from those of Norway, ought to be referred to this genus.

DIATES'SARON, in Greek music, the interval of the Fourth.

DIATON'IC, in music (*διά*, through, and *τόνος*, a tone), a term applied to the first of the three antient genera, and of the three modern scales, but in both cases rather improperly, because the intervals of the Greek genus and of the scale now in use consist not only of tones, but also of semitones. The *Major Diatonic Scale* of the moderns proceeds thus:—

The Diatonic genus of the Greeks, as exhibited in their several *modes*, comprised five tones and two semitones, differently disposed: that of the Lydian mode, according to Sir Francis Styles (*Transactions of the Royal Society*, 1760), corresponded, as regards the position of the intervals, to our major diatonic scale. [SCALE.]

DIASO'MA. [BOTRYLLUS, vol. v., p. 259.]

DIBDIN, CHARLES, in whose person the British bard may be said to have been revived, had his birth at Southampton in 1745, near which place his grandfather, a considerable merchant, founded a village that bears his name. When Dibdin was born, his mother had reached her fiftieth year, and he was her eighteenth child. He had a brother, Thomas, twenty-nine years older than himself, on whose death he wrote the beautiful ballad, 'Poor Tom Bowling.' This gentleman was captain of an East-India-man, and father of Thomas Frognall Dibdin, D.D.

The subject of the present notice was educated at Winchester, and originally designed for the clerical profession, but his love for music predominated, and after receiving some instruction from the celebrated Kent, organist of Winchester cathedral, he was sent to London, and commenced his career, as poet and musician, at the early age of sixteen, when he produced an opera at Covent Garden theatre, written and composed by himself, called *The Shepherd's Artifice*. A few years after he appeared as an actor, and was, in 1768, the original Mungo in his own *Padlock*. In 1778 he became musical manager of Covent Garden theatre, at a salary of ten pounds a week. About the year 1782 he built the Circus theatre (afterwards opened under the name of the Surrey), which continued under his management about three or four years. In 1788 he published his *Musical Tour*, in one vol. 4to.; and in 1789 presented to the public, at Hutchins's auction rooms, King Street, Covent Garden, the first of those entertainments whereby he so eminently distinguished himself,—and of which he was sole author, composer, and performer,—under the title of *The Whim of the Moment*. In this, among sixteen other songs, was the ballad 'Poor Jack,' an effusion of genius that immediately established his reputation, both as a lyric poet and melodist. The year 1791 saw Dibdin in his Sans Souci, an exhibition-room in the Strand, fitted up by him; and in 1796 he erected a small theatre in Leicester Fields, giving it the above-named title. This he sold in 1805, and retired from public life; but not having been provident while the means of making some provision for the future were in his power, his retreat was not accompanied by independence. This having been properly represented, government granted him a pension of 200*l.* per annum, an act evincing both a sense of justice and a right feeling. Of this he was for a time deprived by Lord Grenville, but a more liberal ministry restored it. Towards the close of the year 1813 he was attacked by paralysis, and died in the July following. Mr. Dibdin published one or two novels, and some smaller works, but his fame is built on his songs, of which—so prolific was his muse, and so

great his facility in composition—he produced the amazing number of nine hundred! The character of these, and of their author considered as a writer, is thus given in the *Harmonicon* for April, 1824:—‘Had Dibdin written merely to amuse, his reputation would have been great, but it stands the higher because he is always on the side of virtue. Humanity, constancy, love of country, and courage, are the subjects of his song and the themes of his praise; and while it is known that many a national foe, whether contending or subdued, has experienced the efficacy of his precepts, we are willing to believe that the sufferings which the lower orders of the creation are too commonly doomed to endure have now and then been a little mitigated through the influence of his persuasive verse.’

DICÆARCHUS, the son of Phidias, was born in the city of Messana in Sicily. He was a scholar of Aristotle, and is called a peripatetic philosopher by Cicero (*De Officiis*, ii. 5); but though he wrote some works on philosophical subjects, he seems to have devoted his attention principally to geography and statistics. His chief philosophical work was two dialogues ‘on the Soul,’ each divided into three books, the one dialogue being supposed to be held at Corinth, the other at Mytilene. In these he argued against the Platonic doctrine of the soul, and indeed altogether denied its existence. In the second and third books of the Corinthian dialogue, Cicero tells us (*Tuscul. Disput.* i. 10), he introduced an old Pthiote named Pherecrates, maintaining that the soul was absolutely nothing; that the word was a mere empty sound; that there was no soul either in man or beast; that the principle by means of which we act and perceive is equally diffused throughout all living bodies, and cannot exist separated from them; and that there is no existence except matter, which is one and simple, and whose parts are naturally so arranged that it has life and perception. The greatest performance of Dicæarchus was a treatise on the geography, politics, and manners of Greece, which he called ‘the Life of Greece’ (Ἑλλάδος βίος). Of this a fragment has come down to us, which is printed in Hudson’s *Geographici Minores*, and also edited by Marx in Creuzer’s *Meletemata e Discipl. Antiquitatis*, p. iii., p. 174. It has been conjectured, with great appearance of truth, that the citations from Dicæarchus, in which his treatises ‘on Musical Contests,’ ‘on the Dionysian Contests,’ &c., are referred to, are drawn from this comprehensive work, and that the grammarians have named them by the title of the subdivision to which these subjects belonged, instead of the leading title of the book. (See Näke in the *Rhein. Mus.* for 1833, p. 47.) Dicæarchus’s maps were extant in the time of Cicero (*Ep. ad Att.* vi. 2); but his geography was not much to be depended upon. (Strabo, p. 104.) Cicero was very fond of the writings of Dicæarchus, and speaks of him in terms of the warmest admiration. (*Ep. Att.* ii. 2.) In the extant fragment Dicæarchus quotes Posidippus, and must therefore have been alive in 289 B.C. We must distinguish him from a Lacedæmonian grammarian of the same name, who was a pupil of Aristarchus (see Suidas).

DICÆ/LUS, a genus of Coleopterous insects. [LICINUS.]

DICÆUM. [CREEPER, vol. viii., p. 149.]

DI/CERAS. [CHAMACEA, vol. vi. p. 469.]

DICHELE/STHIUM. [PÆCILOPODA.]

DICHO/LOPHUS. [CARIAMA, vol. vi. p. 291.]

DICHOTOMA/RIA. [PSEUDOZOA.]

DICHO/TOMY, a term in botany, employed to express a mode of branching by constant forking. The first stem or vein of a plant divides into two branches, each branch divides into two others, and so on. It is only in the veins of fern leaves, and of those of some of coniferous species, and in the stems of Lycopodiaceous plants, that this mode of division exists as a general character. It however does occur elsewhere; for example, the Doom Palm of Thebes is remarkable for its dichotomous branches, and the Screw Pines (*Pandanus*) have a similar habit.

DI/CLINOUS, an obsolete term in botany, signifying that a plant has its sexes in distinct flowers. It comprehends all the Monœcious and Diœcious plants of Linnæus.

DICOTYLE/DONS, a natural class of plants, deriving their name from the embryo having in general two seed-leaves, or cotyledons; a character to which there are however some exceptions. The genus *Ceratophyllum* has several; *Bertholletia* appears to have none; in *Tropæolum* and many others they are consolidated into one; and *Cuscuta* is cer-

tainly destitute of them. Like all others, therefore, the character derived from the cotyledons, nearly universal as it is, has its exceptions. Hence botanists associate with the character derived from the embryo others derived from the mode of growth, leaves, flowers, &c., and the whole taken together give the real diagnosis of the class to which the name of Dicotyledons is applied.

The stems of dicotyledons are probably in all cases branched, except when a plant is, from its weakness and minuteness, unable to reach any development beyond that of the first stage from the plumule. In herbaceous plants that are called stemless, a sort of branching takes place by the formation of small short stems upon the crown of the axis of growth. They have the pith, wood, and bark distinctly separated, and the wood traversed by medullary rays. This wood, if more than one year old, consists of concentric circles, each of which is formed on the outside of that which immediately preceded it; the consequence of which is, that the oldest part of a branch will necessarily consist of the largest number of layers, and will therefore be the thickest: hence the branches of dicotyledons are always cones, although usually very long ones [EXOGENS], and not cylinders. But to some of these characters the exceptions are not a few. It is difficult to trace any distinction of pith, wood, and bark in the stem of the water-lily (*Nymphæa*); there are no concentric circles in the wood of *Aristolochia*, and several other genera; and it is impossible to show by measurement that the stems of many irregular tropical dicotyledonous climbers vary perceptibly in diameter for considerable distances.

The leaves of dicotyledons are articulated with the stem, so that at a particular time they are thrown off, and leave a clean scar behind them, as in all the trees, whether deciduous or others, which are found in the open air in England. Their veins are repeatedly branched, so as to form a netted apparatus within the parenchyma. But although by far the largest part of dicotyledons are thus constructed, yet we have contradictions to this also. For instance in *Dianthus*, and a great many other genera, the leaves have no veins except the midrib, and there are many herbaceous plants whose leaves never drop fairly off the stems.

The number of parts in the flower of dicotyledonous plants is four or five; that is, four or five sepals, four or five petals, and the same number of stamens, present in either a complete or imperfect state; or if the number is greater, it is some power of four or five. But in *Ranunculus Ficaria*, most Anonaceous plants, and several more, the parts in the flower are three.

Finally, when the seeds germinate, the embryo simply extends the point of its radicle in the form of a root, to seek for nourishment in the soil. [EXORHIZÆ.] But although this is, as far as is yet known, a character without exception, nevertheless it has been too little studied for us to assert that it is more free from anomalies than other characters.

Hence it is to be observed, that it is neither the two cotyledons, nor the exogenous stem, nor the concentric circles of wood, nor the reticulated disarticulating leaves, nor the quinary or quaternary flowers, nor the exorhizal germinations, which by themselves characterize the class of dicotyledons, but the combination of those characters; and that the absence of some one of them is immaterial; so that a plant may be essentially a dicotyledon, although it has any number of cotyledons except two.

The dicotyledons of Jussieu comprehended the plants now separated under the name of Gymnosperms, and, together with Monocotyledons and Acotyledons, constituted the whole vegetable kingdom. They probably consist of at least two-thirds of all known plants: in the state of trees, shrubs, or herbaceous plants, they are found wherever phænogamic vegetation can exist, and they and Gymnosperms together constitute exclusively the arborescent scenery of all cold countries.

DICO/TYLES. [HOG.]

DICRU/RUS. [LANIADÆ.]

DICTAMNUS, the botanical name of the fragrant herbaceous plant called *Fraxinella* by gardeners.

DICTA/TOR was the highest extraordinary magistrate in the Roman republic. Though the name obviously contains the element *dic* (from *dico*), it was doubted by the Roman writers whether the title had reference to the mode of his nomination or to his power. He was also called by the old name of *Magister Populi*, and in Greek δισίπταρος, or ‘double consul.’ After the expulsion of the kings the

consulship was established. The two consuls possessed the same power as the kings in the administration of the state and the command of the army, yet their authority was subject to some restrictions, and principally by the appeal that could be made from their decisions. [CONSUL.] The two consuls, possessing equal authority, often differed in their views and opinions; a circumstance which necessarily caused jealousy and disunion, particularly in the command of the army when on active service. In extraordinary emergencies, the republic therefore required a single magistrate, invested with ample authority. Such circumstances led to the establishment of the dictatorship. The first dictator was created about the year 253 A.U.C., or 501 B.C. (Liv. ii. 18.)

The dictator united in himself the power of the two consuls; and the authority of all other magistrates, except that of the tribunes, ceased as soon as he was appointed. He possessed the whole administrative power of the state, and the command of the army without any restrictions. (Dion Cassius, according to Zonaras, vii. 13, where a reference to a lost book of Dion is given. Dion Halic., v. 70, 73.) He had the power of life and death, and there was no appeal from his decision. Both within and without the city he was attended by twenty-four lictors, with their fasces and axes. The dictators were not chosen, like the other magistrates, in the comitia, but they were appointed by one of the consuls, in conformity with a vote of the senate. Sometimes the senate itself appointed the dictator, and in some instances he was elected by the comitia. At first he was taken only from the patrician order, but afterwards (B.C. 356) also from the plebeians. After his election, the dictator nominated the master of horse (magister equitum), who commanded under him. It was only when the state was menaced by sudden danger from within or without that a dictator was nominated; but in the course of time a dictator was elected to preside at the elections in the comitia, when the consuls were abroad, and therefore could not preside; and also on some other public solemnities. (Liv. vii. 3; viii. 18 and 23.) The dictator continued in office for six months, but he commonly resigned as soon as the danger was over which had led to the nomination. The dictator was not allowed to leave Italy, or to enter the city on horseback. Yet there are instances in which the dictator left Italy, as for example in the first Punic War, when a dictator commanded in Sicily. The rule that he should continue in office only six months was also neglected; Sylla and Julius Cæsar were nominated perpetual dictators, the former in the year 81 B.C., and the other after his victory at Pharsalus. The office seems never to have been filled from B.C. 202 to the time when Sylla, the head of the oligarchical party, was made perpetual dictator. J. Cæsar, who was the head of the democratic party, or perhaps rather chose that party merely that he might, by being at the head of one of the great divisions which distracted the state, prepare the way for his own unlimited power, after being dictator five times, became dictator for life. Augustus declined the office, though offered to him by the people (Suetonius, *Aug.* 52), and the title of dictator was never assumed by the emperors of Rome.

These are the received opinions as to the Roman dictators; but in Niebuhr's Roman history we find other views of the subject, to which we shall briefly advert. According to him, the dictatorship was of Latin origin, and was introduced from the Latins among the Romans. The object of the Roman dictatorship was to evade the Valerian laws, and to establish the power of the patricians over the plebeians; for the appeal granted by those laws was from the sentence of the consuls, and not from that of the dictator. The later Romans had but an indistinct knowledge of the dictatorship of the ancient constitution. Dion Cassius is in error, when (without excepting the patricians) he asserts that in no instance was there a right of appeal from the dictator, and that he could condemn knights and senators to death without a trial. Dionysius is also in error, when he says that the dictator decided on every measure according to his own pleasure. It is incorrect to suppose that the appointment of the dictator in all cases rested with one of the consuls; for the conferring of kingly power (such as that of the dictator was) could never have been intrusted to a single person. The pontifical books have preserved so much as this, that the dictator was nominated by the senate, and that the nomination was approved by the people. As the plebeians increased in power, the dictatorship was seldom required,

and then only for matters of less importance; and in such cases the nomination was left to the consuls.

For a general sketch of the dictatorial power, the reader may consult Creuzer, *Abriss der Römischen Antiquitäten*, &c., Leipzig, 1824; Niebuhr's chapter on the Dictator, and his *Remarks on the Relationship of the Dictator and the Master of the Horse*, vol. i. Engl. Trans.

DICTIONARY, the English form of *Dictionarium*, a word of low or modern Latinity, which from its etymology should signify properly a book of phrases or modes of expression. The term however has been generally applied to any work which professes to communicate information on an entire subject, or entire branch of a subject, under words or heads digested in the order of the alphabet. This alphabetical arrangement appears to be the distinctive peculiarity of what is called a dictionary; but to constitute the work a dictionary, it should seem that there must also be attached to each of the terms, so arranged, some explanation or interpretation. Thus, an Index, in which words or titles are merely put down in alphabetical order, with nothing more than a reference to some page or passage appended to each, is not a dictionary. The alphabet itself is not a dictionary. Again, a dictionary, however arbitrary or artificial may be the order in which its parts are distributed, must profess some unity and completeness of design. It must profess, as has been said, to go over a whole subject, or field of knowledge, of greater or less extent. Thus a mere list of miscellaneous particulars, even with explanatory remarks or comments annexed, is not a dictionary, but a catalogue. A collection of plays or of pamphlets might be arranged in the order of the alphabet, but would not on that account make a dictionary. That name is not applicable, and is never given, even to the most extensive enumeration and account of things which are merely brought together, without constituting when collected a natural system or complete body of knowledge.

Within the limitations noted, the term dictionary is applied to works on all kinds of subjects, and with every diversity of object. Dictionaries have sometimes been divided into three classes or descriptions:—1. Dictionaries of words. 2. Dictionaries of facts. 3. Dictionaries of things. And although objections may be made to the principle of this distribution (as has been done by D'Alembert in the *Encyclopédie*, article *Dictionnaire*), it is sufficiently convenient for practical purposes, and we shall therefore adhere to it in what we have now to say.

I. Dictionaries of Words. This is the original application of the word dictionary, and the sense in which it is commonly understood when it stands alone. It answers in this sense to the Greek lexicon, and although etymologically that term, like the term dictionary, ought perhaps to signify a book of phrases or modes of expression, yet among the Greeks it seems rather to have denoted a book that explains words. A dictionary or lexicon indeed usually combines an explanation of phrases with an explanation of single words. When it contains nothing beyond an explanation or translation of single words, it is more distinctively called a vocabulary or word-book. The word vocabulary, we believe, is not found in the Latin of antiquity, any more than dictionarium. A glossary, in Latin *glossarium*, which is used by the later classics, from the Greek *glossa* (γλῶσσα), 'a tongue' or 'language,' is generally understood to mean, an explanation, more or less diffuse, of terms of unusual occurrence. Among the Greeks themselves indeed *glossa* was used for a foreign, or otherwise peculiar word or form of expression. (Aristot. *Poet.* c. 38.) As there is nothing in the etymology of the term glossary however to confine it to this explanation, many examples may be found of its employment in a more extended sense. Some dictionaries profess to have more peculiarly for their object the explanation or interpretation of phrases; such, for example, as the well-known volume on the Latin language entitled '*Phraseologia Generalis*,' by William Robertson, 8vo. Camb. 1681. Some dictionaries and vocabularies apply only to some particular author or work; such as Damm's *Lexicons* or *Concordances*, as they are called, of Homer and Pindar, since combined into the *Lexicon Homericum-Pindaricum*, the *Lexicon Ciceronianum* of Marius Nizolius, &c. Such dictionaries, when well compiled, are among the most valuable aids the student can avail himself of. Nor are they of use only in studying the authors of antiquity; the works of some modern writers have been very ably illustrated in this way, as, for instance,

by Mr. Tyrwhitt in his glossary to Chaucer, and by Archdeacon Nares in his glossary to Shakspeare and his Contemporaries, 4to. London, 1822. Even a mere verbal index, with little or no explanation of the meanings of the words, is often much more useful than a professedly interpreting dictionary, by merely bringing together or pointing out by reference the different passages in which each word is used, so that they may be compared with one another. Such mere indexes as those attached to the Delphin Classics are of great value in this way, in addition to their proper use of enabling any passage to be found of which even a single word is recollected. Few of our English classics have been illustrated by such complete verbal indexes; there is one to Milton's *Paradise Lost*, 12mo. London, 1741. Ayscough's Index to Shakspeare is only an index to the 'remarkable' passages and words; and although its professed design is 'to point out the different meanings to which the words are applied,' it is not very successfully compiled for that purpose. Still it is a useful book, as being the best verbal index to Shakspeare we yet possess. Indexes of this description serve in fact the same purpose with Concordances, although that term has been for the most part confined to works relating to the Scriptures. (CONCORDANCE.) Some works entitled dictionaries, indeed, comprehend concordances more or less complete; as, for instance, Schleusner's *Novum Lexicon Græco-Latinum in Novum Testamentum*, and the Ionic lexicon of Schweighæuser, which is a sort of concordance to Herodotus, and that to Polybius by the same scholar.

Some of these dictionaries to particular authors, or works, have exclusively or principally in view the illustration of the style of the author, or his use of particular words. One of the best of these is Ernesti's *Index Latinitatis Philologico-Criticus* to Cicero. This work in fact, although styled merely an index, is much more a dictionary of interpretation and commentary than the lexicon just mentioned of Nizolius, which however is much the more minute and extensive index of the two. The instance may serve to show with what latitude the two titles are applied. And the title of index, it may be added, has been sometimes given to works which are not really indexes in any respect, but simply dictionaries or vocabularies. We may mention as an example, *Olai Vereli Index Linguae Veteris Scytho-Scandicæ, sive Gothicæ, opera Olai Rudbeckii editus*, fol. Upsalæ, 1691, which is merely a vocabulary of the Gothic. Dictionaries of languages have also been published under many other titles. A *Thesaurus*, or *Treasury*, is a very common title of such a book. Thus Faber's Latin dictionary is styled *Thesaurus Eruditionis Scholasticæ*, and H. Stephens' Greek lexicon is entitled *Thesaurus Græcæ Linguae*. Edward Philips entitles his English dictionary a *World of Words*. In some cases an attempt has been made by means of a dictionary or index, not only to point out the writer's use of particular words, or their meaning in particular passages of his works, but also to give an abstract of his text. This has been done in the index to Hippocrates, by Fœsius, entitled *Œconomia Hippocratis Alphabeti serie distincta, in qua Dictionum apud Hippocratem omnium, præsertim obscuriorum, usus explicatur, et velut ex amplissimo Penu depromitur, ita ut Lexicon Hippocrateum merito dici possit*, fol. Francf. 1688. Of dictionaries of words also, some are dictionaries of etymologies, some of the quantities of syllables (as the common Latin *Gradus ad Parnassum*, and Morell's *Thesaurus Græcæ Poeseos, sive Lexicon Græco-Prosodiacum*, improved and enlarged by Maltby); some of terminations (as in English, Walker's *Rhyming Dictionary*), and Hoogeveen's *Dictionarium Analogicum Linguae Græcæ*. Some dictionaries of the oriental tongues and of the Greek tongue exhibit the words arranged according to their supposed roots; and some Latin dictionaries have also been constructed upon this plan. Of professed dictionaries of derivations one of the most elaborate, though it is far from being a correct or philosophical work, is the *Etymologicon Linguae Latinæ* of G. J. Vossius. Others are the *Dictionnaire Etymologique de la Langue Française*, of Menage; the *Origines de la Langue Italienne*, of the same author; the *Etymologicon Linguae Anglicanæ*, of Stephen Skinner, fol. 1671; and the *Etymologicon Anglicanum* of Francis Junius, fol. Oxon, 1743. A very ambitious attempt has been made by Mr. Whiter in his *Etymologicon Magnum, or Universal Etymological Dictionary on a new plan*, 3 vols. 4to., Camb. 1800—1822, to construct a dic-

tionary of the elements of all human language. Mr. Booth, in his *Analytical Dictionary of the English Language*, has set an example of perhaps the happiest mode in which an account of words can be given according to their etymologies or affinities. By making each radical term the text of a short essay, in the course of which the history of all its derived and connected terms is traced and illustrated by quotations, references to manners and customs, and anecdotes of various kinds, the writer has rendered his dictionary as entertaining as it is instructive, and adapted it not only for occasional consultation but for continuous reading.

Any account of the dictionaries of particular tongues would be out of place here. There is a *Table Alphabetique des Dictionnaires*, by Durey de Noinville, published in 1758, which however is asserted to be very incomplete, even for that time. A very elaborate dissertation on lexicons and glossaries in general, and on those of the Greek language in particular, by P. J. Maussacus, is inserted in most of the editions of the Greek lexicon of Harpocration, entitled *Lexicon Decem Oratorum*; and the same subject has also been treated by several other writers who are enumerated in Morhoff's *Polyhistor*, lib. iv. cap. 7. In the portion of Morhoff's third book, from chapter 4th to chapter 9th inclusive (vol. i. pp. 743—830, edit. 1747), is given an account of the principal dictionaries of the modern European tongues, of the oriental tongues, of the Greek, and of the Latin tongues. See also De Bure's *Bibliographie Instructive*, vol. iii., p. 1—86.

In some dictionaries the words are explained in the same language to which they belong; in many others the words of one language are interpreted by corresponding words in another language. In some the interpretation or translation is into several languages; as, for instance, in Minsheu's *Dictionary of Eleven Languages*, namely, English, Welsh, German, Dutch, French, Italian, Spanish, Portuguese, Latin, Greek, and Hebrew, fol. London, 1617; and in a dictionary printed at St. Petersburg in 3 vols. 4to., in 1785, in which the words and phrases are given in French, German, Russian, and Latin.

Although, as Maussacus in his *Critical Dissertation* just noticed has taken great pains to prove, books both of *γλῶσσαι*, or unusual words, and of *λέξεις*, or idioms, are frequently referred to or mentioned by the Greek and Latin grammarians and other writers, it does not clearly appear that all of these were what we should now call dictionaries, that is to say, were collections of vocables and phrases alphabetically arranged. The oldest extant Greek lexicographer is Apollonius the Sophist, a contemporary of Augustus; his work entitled *Λέξεις Ὅμηρικαί*, or *Homeric Words*, though much interpolated, is very useful. All the other original Greek lexicons and glossaries we have, such as the *Onomasticon* (or *Collection of Synonymes*) of Julius Pollux, the lexicons of Suidas, Harpocration, and Hesychius, and the *Etymologicon Magnum*, sometimes attributed to Marcus Musurus, although of the authors of some of them the exact age is disputed, were undoubtedly compiled subsequent, and most of them probably long subsequent to the commencement of the Christian æra. It is supposed indeed that they were founded upon older compilations of the same kind; but of the form of those lost works we know nothing. It may be reasonably doubted if either the Greeks or Romans were in the habit of making use of dictionaries in studying a foreign language or dialect, as has been the general practice in modern times. They would seem rather to have uniformly followed what may be called the natural method of learning the language from conversation with those who spoke it, being the method by which we all learn the language we acquire both most easily and most perfectly, our mother tongue, and that by which alone a real knowledge and command of any language can be acquired. Although, however, the utility of a general dictionary of a language as an instrument either for teaching the language to youth in schools, or for enabling a student to master it in any circumstances, may well be questioned, there are obvious considerations which make it desirable that we should possess such dictionaries of all languages. When a dictionary of a language professes to be more than a mere vocabulary, it is usual for it to contain along with the interpretation or explanation of the meaning of each word, some account of its etymology or derivation, and also of its grammatical usage. Except when the dictionary is exclusively etymological, perhaps all that ought to be attempted in regard to

the foreign extraction of words is to note the language from which each may be supposed to have been immediately borrowed. But merely to append the supposed original word of the foreign language, as is generally done, conveys little valuable information in any case, and is very apt to lead to misconception. If it is desired to exhibit the nature of the change which the forms of the words have undergone in passing from the one tongue to the other, this will be better done by a short statement on the subject once for all, in which the several modes and incidents of the transference should be systematically arranged and illustrated by examples, and the principle of each explained. It would be of fully as much importance however that in every dictionary of a language the connection of each word with other words in the same language, or the native root from which each has sprung, should be distinctly marked whenever it is not obvious. This reference of each word to the proper family to which it belongs contributes more to make its meaning clear and to point out its correct use than any definition can do. And such a notice of the root of the word would naturally lead to, and should be followed by, as precise a statement as possible of its primitive and most simple meaning; after which should come a chronological deduction of the changes it has undergone, as far as they can be traced, both in signification and in form, the whole definition being concluded by an explanation of its metaphorical and other secondary or transferred meanings. If its use in each sense can be illustrated by an example, such quotations are, for various reasons, in the highest degree satisfactory and valuable. Any remarkable uses of the word in particular passages of standard authors ought at least to be adverted to and explained; and a notice of its peculiarities of construction, or the manner in which it is connected with other words in a sentence, should never be omitted. There are some dictionaries in which all this has been attempted, but perhaps scarcely one in which it has been quite satisfactorily executed. Among the most carefully compiled dictionaries of modern languages are that of the Italian, entitled *Vocabolario degli Accademici della Crusca*, extended in the latest editions to 6 vols. fol.; and that of the French, entitled *Dictionnaire de l'Académie Française*. But in both these works, especially in the latter, the design principally kept in view has been to guard the purity of the language. There is also a Spanish dictionary of great reputation, entitled *Diccionario de la Lengua Castellana*, compuesto por la Real Academia Española, 6 vols. fol., Madrid, 1726, &c. In English, Johnson's Dictionary has been accounted the standard work of its class ever since its appearance, in 2 vols. fol., 1755; but although it was a great achievement for an individual, and its definitions in particular afford remarkable evidence of its author's ingenuity and command of expression, it is in many respects as far as possible from being what a dictionary should be. Its etymological part (as Horne Tooke has long ago shown) is little better than so much rubbish; and it is characterized throughout by a total want of method and philosophical views. Its author indeed was neither metaphysician, nor linguist, nor archæologist enough for the task he undertook. Some valuable matter has been added to the last edition of the English Dictionary (augmented to 6 vols. 4to.) by the Reverend Mr. Todd; but the philosophical character of the work has received no improvement in his hands. Perhaps the nearest approach that has been made to a philosophical English dictionary would be that given in the miscellaneous and lexicographical department of the *Encyclopædia Metropolitana*, if the execution were equal to the design, which is explained in the prospectus as being to exhibit 'the history of English words; the citations arranged according to the age of the works from which they are selected, yet with every attention to the independent beauty or value of the sentences chosen which is consistent with the higher ends of a clear insight into the original and acquired meaning of every word.'

II. Dictionaries of Facts. This class comprehends dictionaries of history, biography, mythology, geography, archæology, and all others that deal chiefly or exclusively with events that have happened, or are supposed to have happened, or with facts that exist or have existed. Many of the principal works of this description are enumerated in the article BIOGRAPHY: and under BIBLIOGRAPHY will be found an account of another large division of them. We may here observe that some of the old Greek lexicons already noticed were dictionaries of facts as well as of words; the

lexicon of Suidas, for instance, is, in the greater part, made up of fragments of biography, history, and geography, and often contains large extracts from various writers both extant and lost. The work of Stephanus Byzantinus, sometimes entitled *Ἑθνικά* (the Ethnology), more commonly *Περὶ Πόλεων* (the Book of Cities, or rather of States), is chiefly a geographical and archæological dictionary, and is the oldest compilation of that description that exists. Its meagre details under each head assimilate it in some respect to an imperfect gazetteer. In modern times the number of dictionaries that have appeared, professing to present a view of a more or less extensive field of facts, has been very great. Besides the various historical, biographical, and geographical dictionaries, general and particular, and the bibliographical dictionaries, there are dictionaries of antiquities, of architecture, of heraldry, of painting, of music, of botany, of law, of legal decisions, of commerce, of medicine, of surgery, and of almost every other department of human knowledge. Human knowledge, however, or what is commonly called or reckoned such, in almost all its departments, is such a mixture of ascertained facts and of mere opinions or speculations, that there is hardly any of these dictionaries which is a dictionary of facts merely. Opinions, indeed, considered historically, are themselves facts, and as such ought to be recorded and arranged in dictionaries as well as other facts. Discussion also often places doubtful facts in a clearer light, and a dictionary may be as convenient a vehicle for such discussion as any other book. But a most useful class of books, of which we have yet scarcely a specimen, would be a set of dictionaries or tabular expositions of facts, and nothing else. They would serve, among other purposes, as maps of the extent and boundaries of the different departments of human knowledge, and most useful directories in the prosecution of all inquiries having in view the enlargement of those boundaries. As of facts some are completely ascertained, others only probable, and others doubtful, three divisions answering to these descriptions might be given under each head, and a fourth might perhaps be advantageously added for improbable or confuted statements, although these last might be more scientifically exhibited in the table or dictionary of the facts forming the history of opinions.

III. Dictionaries of Things. A thing, as seems to be indicated by the Latin *reor*, which apparently contains the same root as *res*, as well as by the English *think*, is properly any object of thought; and under this title may therefore be comprehended dictionaries of all other kinds, except those exclusively occupied with the explanation of words or the notation of facts. This division leaves to the third class of dictionaries all the abstract sciences, the mixed or applied sciences, the departments of criticism and the fine arts, and the whole range of metaphysical and moral speculation. It is true that some of these subjects cannot be treated of without a reference to facts; but the facts here are not viewed simply as such, but either as subordinate to principles or as modifying their operation. No very rigorous adherence to the limits of a definition however is to be expected in a dictionary of any kind, which must in all cases be a somewhat unsystematic performance, and accordingly we have few, if any, dictionaries which are exclusively dictionaries of things in the sense that has just been explained. Many of the dictionaries referred to under the last head are dictionaries of things as well as of facts: that is to say, they contain, mixed up with their statements of facts, expositions or discussions of principles. On the other hand, dictionaries of things are generally also dictionaries of facts, and sometimes lexicons, or dictionaries of words and phrases, in addition. The most important works of this description have been published under the title of Dictionaries of the Arts and Sciences, or Encyclopædias. By the word *ἐγκυκλοπαιδεία*, encyclopædia, the Greeks seem to have understood the whole circle of learning or of the liberal arts, or instruction therein, the term being so applied under the notion that all the departments of human knowledge were naturally connected together so as to form a sort of circle or complete system. Pliny (*Nat. Hist. Præf.*) speaks of the encyclopædia of the Greeks as an expression for the whole field of knowledge: 'Jam omnia attingenda, quæ Græci τῆς ἐγκυκλοπαιδείας vocant.' Quintilian (i. 10) defines it as the orb or complete circle of human learning: 'Orbis illa doctrinæ, quam Græci ἐγκυκλοπαιδίαν vocant.' Vitruvius (vi. Præf.) describes the encyclos or ἐγκύκλιος παιδεία of the Greeks as the discipline of all the branches of learning: 'doctrinarum omnium disciplina.' It

does not appear that the term encyclopædia was ever antiently used as meaning a work treating of all the various kinds of knowledge. It has, however, as just observed, become the common title for such works in modern times. Perhaps it was first so applied by some of the Arabian writers of the middle ages, one of whom at least, Alfarabius, who flourished in the tenth century, is stated to have compiled a general treatise on the sciences, still preserved, under this title. Several such treatises with the same title appeared in Europe about the end of the sixteenth and beginning of the seventeenth centuries, the most famous of which was that of John Henry Alstedius, which was first published in 2 vols. fol. in 1630. (See preface to Supplement to Encyclopædia Britannica, and Morhoffii Polyhistor, vol. i. lib. ii. chap. 7, for an account of this and other early encyclopædias.) But none of these works were dictionaries: they were merely collections of treatises, rather resembling such works as Dodsley's Preceptor than answering to the modern notion of an encyclopædia. A much nearer resemblance to the modern encyclopædia is presented by the 'Lexicon Universale Historico-Geographico-Chronologico-Poetico-Philologicum' of Joh. Jac. Hofman, first published at Basle in 2 vols. fol., 1677, and followed by a 'Continuatio' or Supplement, of the same extent, in 1683; or, the two publications incorporated in 4 vols. fol., Lug. Bat., 1698. The form at least of this work has been generally preserved in our more recent encyclopædias and dictionaries of the arts and sciences, although most of these, by including the principles of science as well as facts, have extended their scope somewhat beyond Hofman's design. His two supplementary volumes however embody a great deal of the natural science of his time; and the work altogether contains much curious learning not readily found elsewhere. Although not evidencing any very superior sagacity, penetration, or elegance of scholarship, it is a wonderful performance for an individual, and still remains a most useful book of reference.

The first English 'universal dictionary of the arts and sciences' was the 'Lexicon Technicum' of Dr. John Harris, of which the first vol. in fol. appeared at London in 1706, and the second, completing the work, in 1710. It was afterwards extended to three volumes. Harris's Lexicon enjoyed great popularity for a considerable time after its first appearance, as may be inferred from the fact that it passed through five editions in about thirty years; and in the mathematical and physical department especially it is admitted to have been very ably executed. It was not long however before it found a rival in Chambers's Cyclopædia, the first edition of which appeared in 2 vols. fol. in 1728. [CHAMBERS, EPHRAIM.] The professed peculiarity of the new work was, that it proposed to 'consider the several matters not only in themselves, but relatively, or as they respect each other; both to treat them as so many wholes, and as so many parts of some greater whole.' This was attempted to be done by a system of references from one article to another, so as to connect the subordinate particulars among themselves, and to indicate the great division of knowledge to which each belonged. In this way the work, which, in the seventh edition (1778—85), was extended to 4 vols. folio, contained no complete treatises on any of the sciences, nor other articles of any considerable length. Various other works followed, compiled upon much the same plan, among which were Barrow's 'New and Universal Dictionary of Arts and Sciences,' in one vol. fol. 1751, with a supplemental vol., published in 1754; 'A new and complete Dictionary of Arts and Sciences, by a Society of Gentlemen,' (commonly, from the name of the publisher, called Owen's Dictionary,) 4 vols. 8vo., 1754; and 'The Complete Dictionary of Arts and Sciences,' in 3 vols. fol., 1766, by the Rev. Henry Croker, Dr. Thomas Williams, and Mr. Samuel Clark. (See, for an account of all these works, the preface to the Supplement to the Encyclopædia Britannica.)

A work upon a different plan had also appeared in 2 vols. fol. in 1745, by Dr. De Coetlogon, a native of France, naturalized in England, under the title of 'An Universal History of Arts and Sciences, or a Comprehensive Illustration of all Sciences and of all Arts.' This was in fact a dictionary, the subjects being treated in alphabetical order, and Mr. Macvey Napier, in the preface just referred to, considers it to have probably suggested the Encyclopædia Britannica, the first edition of which, in 3 vols. 4to., appeared at Edinburgh in 1771. It professed to be compiled 'by a Society of Gentlemen in Scotland, upon a new plan,

in which the different sciences and arts are digested into distinct treatises or systems.' This plan however had been already adopted in Dr. Coetlogon's work. The proprietor and principal compiler of the Edinburgh work was Mr. William Smellie, the printer, a man of much ability and considerable literary attainments. For the subsequent history of the Encyclopædia Britannica, which in the fourth edition completed in 1810 was extended to 20 vols., and to which a supplement in 6 vols. was added in 1824, we must refer to Mr. Napier's preface. A seventh edition of the work, in which the supplement is incorporated, is now in the course of publication. Of the other modern English Cyclopædias, already completed, the two most deserving of notice are the Cyclopædia, or a New Universal Dictionary of Arts and Sciences, conducted by the late Dr. Rees, and commonly known by his name, although professing to be only a new edition of Chambers, begun in 1802, and completed in 45 vols. 4to. in 1819; and the Edinburgh Cyclopædia, edited by Dr. (now Sir David) Brewster, begun in 1810, and completed in 36 parts, or 18 vols. 4to. in 1830. The Encyclopædia Metropolitana was begun in 1818, being announced as a Universal Dictionary of Knowledge on an original plan; comprising the twofold advantages of a philosophical and an alphabetical arrangement. This work, which is still in course of publication, is arranged in four divisions; the 1st, comprehending the Pure Sciences; the 2d, the Mixed and Applied Sciences; the 3d, the Biographical and Historical articles; and the 4th, the Miscellaneous and Lexicographical articles. The Penny Cyclopædia of the Society for the Diffusion of Useful Knowledge was begun in 1833, and has ever since been published regularly in volumes and in numbers.

Of the foreign works of this class by far the most celebrated is the Encyclopédie, or Dictionnaire Raisonné des Sciences, des Arts, et des Métiers, of Diderot and D'Alembert, of which the first vol. fol. was published at Paris in 1751; the 17th and last of the original series in 1765, 11 vols. of plates being added to the text, of which the first was published in 1762, the last in 1772. A Supplement was afterwards added, consisting of four vols. of text and one of plates, fol., 1776-7; and there is besides a 'Table Analytique' of the whole work, compiled by M. Mouchon, in 2 vols. fol., Paris and Amsterdam, 1780. Editions of the work have also been printed in France and other parts of the Continent, both in quarto and octavo. But the more detailed history of this remarkable work must be reserved for a separate article. It has been followed in France by another Dictionary of Arts and Sciences of still greater extent, the Encyclopédie Méthodique, begun in 1782 and finished in 1832, in 201 vols. 4to., including 47 vols. of plates. In this last-mentioned work every art or science is treated of in a separate volume, or series of volumes; so that the whole is in fact merely a collection of dictionaries. Of other foreign Encyclopædias we may notice the German 'Conversations Lexikon' (as it was originally entitled), projected by Mr. Brockhaus, the bookseller of Leipzig, and first published there in 1812. A seventh edition of this work appeared at Leipzig in 1827-9, under the new title of Allgemeine Deutsche Real-Encyclopädie für die gebildeten stände. An English translation of it, including much additional matter, has appeared at Philadelphia; and the American work is at present in course of republication in this country, with additions and alterations. There is also now in course of publication the great work conducted by Professors Ersch and Gruber, entitled 'Allgemeine Encyclopädie der Wissenschaften und Kunste,' which began to be published at Leipzig in 1818, and of which 46 vols. 4to. have already appeared; viz. the portion from A to Drury, in 27 vols.; that from H to Hamburg, in 12 vols.; and that from O to Otzenhausen, in 7 vols. Some account of the encyclopædias in various languages, but neither very clearly nor very accurately drawn up, and mixed with a great deal of superfluous and useless matter, may be found in a little book called 'Nouveau Système Bibliographique mis en usage pour la connaissance des Encyclopédies,' &c., 12mo., Paris, 1821.

DICTUOPHYLLIA. [MADREPHYLLICEA.]

DICTYS, a Cretan who accompanied Idomeneus to the siege of Troy, and the reputed author of a history of the Trojan war, of which a Latin prose translation is still extant. This work was discovered in the reign of Nero, in a tomb near Gnossus, which was laid open by an earthquake. It was written in Phœnician characters, and translated into

Greek by one Eufraxidas, or Praxis, at the command of Nero: this translation has not come down to us: the Latin version which we possess is attributed to Quintus Septimius, who lived in the third or fourth century A.D., and contains the first five books, with an abridgment of the remainder. The best edition is that by Perizonius (1702, 8vo.), to whose preliminary dissertation the reader is referred for further particulars respecting the historian and his translator.

DIDE'LPHIDÆ. [MARSUPIALIA.]

DIDERMUM. [SYNOICUM.]

DIDERO'T, DENYS, was born at Langres in the province of Champagne, in 1713. His father, a master cutler, a worthy man, much respected in his native town, and comfortable in his circumstances, placed his son first in the Jesuits' College at Langres, and afterwards sent him to the College d'Harcourt at Paris to continue his studies. At one time young Diderot was intended for the church, but as he felt no inclination for the clerical profession, his father did not press the point. Diderot made some progress in the antient and modern languages, and still more in mathematics. On leaving college, his father placed him as a boarder with a Paris procureur, in order that he might study the law, but Diderot had no taste for that profession; he made no progress in its study, and he employed all the time he could steal from the office-desk in reading any books that fell into his hands. After two or three years, his father stopped his board wages, desiring him either to betake himself to some profession or to return home, and he several times repeated the offer of this alternative, but to no purpose, as Diderot replied that he felt no inclination for any worldly profession; that he loved reading, was happy, and wanted nothing more. For ten years from that time he lived obscurely in Paris, on his wits as the phrase is, and often, as it may be supposed, in very promiscuous company. Literature was not then a very marketable commodity, but Diderot had a facility in writing, and he undertook anything that came in his way, advertisements, indexes, catalogues, and even sermons for the colonies, which were bespoken and paid for by a missionary. He next began translating from the English for the booksellers. He also received indirectly assistance from home. At the age of 29, he married a young woman as poor as himself, who proved to him ever after a virtuous and affectionate wife, notwithstanding his subsequent neglect of her. In his drama '*Le Père de Famille*' he has drawn from life some of the incidents of his courtship and marriage. His first original work was the '*Pensées Philosophiques*,' 1746, a desultory and rather common-place production, which however met with great success among the partisans of the new philosophy, as it was then called. From that time Diderot ranked as one of the most strenuous assailants of the established systems in religion and politics. He saw many unseemly parts in the social edifice, and could devise no better mode of mending them than by pulling down the whole. That the state of France under the Regent and Louis XV. was such as easily to lead an impetuous mind to such a conclusion, is made sufficiently evident by the numerous memoirs of those times. In 1749 he published the '*Lettres sur les Aveugles*,' for which he was imprisoned for three months at Vincennes, where however he was very indulgently treated, and allowed to receive the visits of his friends, among whom was J. J. Rousseau, to whom it is said that Diderot suggested the idea of his first literary paradox. They afterwards quarrelled upon some foolish ground, and the squabble was not creditable to either. [ROUSSEAU.] After editing, in company with others, a Universal Medical Dictionary, Diderot formed the project of a general Cyclopædia, to supersede the French version of Chambers's work, and he found a bookseller, Lebreton, willing to undertake the publication, under the title of '*Encyclopédie, ou Dictionnaire Raisonné des Sciences, des Arts, et Métiers*.' Diderot and D'Alembert were joint editors, but D'Alembert withdrew after a time, and Diderot remained sole editor. The work began to appear in 1751, and was concluded in 1765, in 17 vols. fol. besides 11 vols. of plates. The publication was stopped two or three times by the government, and the last volumes were distributed privately, though the king himself was one of the purchasers. The most amusing part of the correspondence of Voltaire and D'Alembert was carried on while D'Alembert was joint editor of the Dictionnaire, and presents a lively picture of the various difficulties with which the editors had to contend. On this

celebrated compilation Diderot himself passed a severe judgment. He said, 'that he had had neither time nor the means of being particular in the choice of his contributors, among whom some were excellent, but most of the rest were very inferior; that moreover the contributors, being badly paid, worked carelessly; that, in short, it was a patch-work composed of very ill-sorted materials, some masterpieces by the side of schoolboys' performances; and that there was also considerable neglect in the arrangement of the articles, and especially in the references.' Diderot complained likewise that the publisher, Lebreton, often took upon himself to scratch out of the proof-sheets any passages which he thought might endanger him, and then filled up the gap as well as he could. Notwithstanding all these deficiencies the Dictionnaire Encyclopédique met with great success for a time, but it has been since superseded in France by the *Encyclopédie Méthodique*, or great French Cyclopædia.

The works of Diderot are numerous, and many of them were not published till after his death. Among those published in his lifetime are: '*Lettres sur les Sourds et Muets*,' 1751; '*Pensées sur l'Interpretation de la Nature*,' 1754; '*Code de la Nature*,' 1755. The principal faults of his didactic compositions are obscurity in the ideas, and a declamatory style. Among his tales, '*Jacques le Fataliste*' and '*Le Neveu de Rameau*,' a posthumous publication, are still popular. '*Les Bijoux Indiscrets*,' are a series of obscene stories, which he sold to a publisher, and gave the money to his mistress, Mad. de Puisieux. He afterwards formed a connection with Mdlle. Voland, it seems, which lasted till his death. His letters to her form the principal part of the '*Mémoires, Correspondence, et Ouvrages Inédits de Diderot*,' published in 1831, 4 vols., 8vo. Diderot's notions on the sexual connection may be seen in the article '*Marriage*,' in the '*Dictionnaire Encyclopédique*,' as well as in several of his '*Ouvrages Inédits*.' He professed a strict sense of honour, and was generous and kind, though hasty, touchy, and suspicious. An estimate of his character may be formed not from the reports of his admirers or enemies, and there were many of both, but from his own works, and especially his correspondence, and also from a well written and apparently unsophisticated memoir of his life by his daughter, Mad. de Vandeuil, which is printed at the head of the unedited correspondence above mentioned. A collection of his principal works was published by his disciple Naigeon, in 15 vols., 8vo., 1798, and reprinted since in 22 vols., 8vo., Paris, 1821, with a life of the author by Naigeon himself, which however is rather a dissertation on Diderot's writings and opinions than a real biography. His last work, a life of Seneca, of which he published a second edition enlarged, in 2 vols., under the title of '*Essai sur les Règnes de Claude et de Néron*,' is considered by some one of his best compositions. It has been said of him that there are many good passages in all his works, though he never wrote a single entirely good work. Marmontel, Garat, and others of his contemporaries preferred his conversation greatly to his writings.

Diderot had not grown rich by his literary labours; he was getting old, and he thought of selling his library. Catherine of Russia hearing of his intention, purchased it at its full value, and moreover settled upon him a handsome pension as librarian to keep it for her, of which pension she paid him fifty years in advance in ready money. Full of gratitude, Diderot resolved to go and thank his benefactress in person. He went first to Holland, where he spent some months, and thence to Petersburg. He was delighted with his reception by the empress, and wrote to Mdlle. Voland that 'while in a country called the land of freemen (meaning probably Holland) he felt as a slave; but now in a country called the country of slaves, he felt like a freeman.' (*Correspondance Inédite*, vol. iii., lettre 138.) After a short stay at Petersburg, he returned to Paris, where the empress hired a splendid suite of apartments for him in the Rue Richelieu. 'He enjoyed his new lodgings only twelve days: he was delighted with them; having always lodged in a garret, he thought himself in a palace. But his body became weaker every day, although his head was not at all affected, and he was quite conscious that his end was approaching. The evening before his death he conversed with his friends upon philosophy, and the various means of attaining it. "The first step towards philosophy," said he, "is incredulity." This remark is the last which I heard him make.'—(*Memoir of Diderot*, by his Daughter.) Next day, 30th July, 1784,

he got up, sat down to dinner with his wife, and afterwards expired without a struggle. Diderot was one of the principal members of the Holbach coterie, and the leader of that knot of literary men known in the last century by the name of Encyclopédistes. There are many particulars concerning Diderot in his friend Grimm's *Correspondance Littéraire*, Paris, 1812.

DIDIUS JULIANUS, of a family originally from Milan, and grandson of Salvius Julianus, a celebrated jurist, was born about A.D. 133. He was educated by Domitia Lucilla, the mother of Marcus Aurelius. He soon rose to important offices, was successively Quæstor, Prætor, and Governor of Belgic Gaul, and having defeated the Chauci, he obtained the Consulship. He was afterwards sent as governor to Dalmatia, and next to Germania Inferior. Under Commodus, he was governor of Bithynia: on his return to Rome, he lived in luxury and debauchery, being enormously rich. After the murder of Pertinax, A.D. 193, the Prætorians having put up the empire to auction, Didius proceeded to their camp, and bid against Sulpicianus, the father-in-law of Pertinax, who was trying to make his own bargain with the soldiers. Didius having bid highest, was proclaimed, and was taken by the soldiers into Rome. The Senate with its usual servility acknowledged him emperor, but the people openly showed their dissatisfaction, and loaded him with abuse and imprecations in the Circus when he assisted at the solemn games which were customary on the occasion of a new reign. He is said to have borne the insult with patience, and to have behaved altogether with great moderation during his short reign. Three generals at the head of their respective legions, Pescennius Niger, who commanded in the East, Septimius Severus in Illyricum, and Claudius Albinus in Britain, refused to acknowledge the nomination of the Prætorians. Severus being proclaimed Augustus by his troops, marched upon Rome, and found no opposition on the road, as the towns and garrisons all declared for him. The Prætorians themselves forsook Didius, and the Senate readily pronounced his abdication, and proclaimed Severus emperor. A party of soldiers making their way into the palace, and disregarding the entreaties of Didius, who offered to renounce the empire, cut off his head. He had reigned only sixty-six days. Severus soon after entered Rome, put to death the murderers of Pertinax, disarmed the Prætorians, and banished them from the city. (Spartianus in *Historia Augusta*; Dion, *Epitome*, B. 73.)

Coin of Didius.

British Museum. Actual Size. Copper. Weight, 355 grains.

DIDO. [ÆNEAS; CARTHAGE.]

DIDUS. [DODO.]

DIDYMUS, a celebrated grammarian, the son of a seller of fish at Alexandria, was born in the consulship of Antony and Cicero, B.C. 63 (Suidas, sub v.), and lived in the reign of Augustus. Macrobius calls him the greatest grammarian of his own or any other time. (Saturn. v. 22.) According to Athenæus (iv. p. 139, C.) he published 3,500 volumes, and had written so much that he was called the forgetter of books (βιβλιολάθας), for he often forgot what he had written himself; and also the man with bowels of brass (χαλκέντερος), from his unwearied industry. To judge from the specimens of his writings given by Athenæus, we need not much regret the loss of them. His criticisms were of the Aristarchian school (Suid.): he wrote, among other things, an explanation of the Agamemnon of Ion (Athen. xi. p. 418 D.), and also of the plays of Phrynichus; (Id. ix. p. 371 F.) several treatises against Juba, king of Libya (Suid. Ἰόβας), a book on the corruption of diction (Athenæus, ix. p. 368 B.), a history of the city Cabessus

(Steph. Byz. sub v. Ἀγάθυρσοι), besides essays on the country of Homer, the mother of Æneas, and other equally unimportant subjects. The *Scholia Minora* on Homer have been attributed to him, but wrongly, for Didymus himself is quoted in these notes. The collection of proverbs extant under the name of Zenobius was partly taken from a previous collection made by Didymus, and about sixty fragments of his fifteen books on agriculture are preserved in the collection of Cassianus Bassus. [GEOPONIKA.]

Suidas mentions several other authors of this name, and among them one surnamed Ateius, who was an academic philosopher, and wrote a treatise in two books on the solutions of probabilities and sophisms. We may also mention Didymus 'the blind,' an Alexandrian father of the church, who was born about the year 308 B.C., and was the teacher of St. Jerome, St. Isidore, Rufinus, and others. He died in B.C. 395. Of his numerous writings, four treatises have come down to us. I. 'On the Holy Spirit.' II. 'On the Trinity.' III. 'Against the Manicheans.' IV. 'On the Canonical Epistles.' A Greek Treatise on Farriery by another Didymus is also extant.

DIDYNA'MIA, the fourteenth class of the Linnæan system of arranging plants. It is the same as Tetrandria; that is, it has always four stamens, only two of them are a little longer than the other two. Under this class are comprehended a large part of the Lamiaceous, Verbenaceous, Scrophulariaceous, Bignoniaceous, and Acanthaceous plants of modern botanists. It is divided into two orders, Gymnospermia and Angiospermia. Gymnospermia includes the genera whose ovary is split into four small seed-like lobes, which in the time of Linnæus were taken for naked seeds; and Angiospermia those which have manifestly the seeds inclosed in a pericarp of some sort.

DIE. [DRÔME.]

DIE' or DIEY, ST., an episcopal town of France, in the department of Vosges, on the river Meurthe, not far from its source, and on a road to Schelested and Colmar, which branches off from the great Paris and Strasburg road at Luneville. It is 252 miles from Paris; in 48° 17' N. lat., and 6° 56' E. long.

This town is of considerable antiquity: it had in the seventh century an abbey called the Abbey of Jointure: this abbey was secularized in the tenth century: the chief of the college of priests thus formed bore the title of *grand prévôt*, and exercised the functions of a bishop: he was also, in conjunction with the chapter, which consisted of twenty-four prebendaries, including three dignitaries, lord of the town. The list of the *grands prévôts* included one pope, nine princes of the house of Lorraine, and several other illustrious persons. St. Dié was walled in in the thirteenth century; the walls yet remain. It is situated at the foot of a mountain, and is small, but regularly laid out, and handsome. In the middle of the last century it suffered much from a fire, which consumed many of the houses. The population in 1832 amounted to 5560 for the town itself, or 7707 for the whole commune. The inhabitants are engaged in the manufacture of cotton yarn, printed calicos, and handkerchiefs, cotton counterpanes, flannels, and hosiery, and leather; and the bleaching of linen is carried on. There are two mineral springs near St. Dié; one impregnated with sulphur, the other with iron.

The bishopric of St. Dié was established in 1777: the diocese now comprehends the department of Vosges (population, in 1832, 397,987): the bishop is a suffragan of the archbishop of Besançon. St. Dié is the capital of an arrondissement, which had, in 1832, a population of 107,804. The inhabitants of this arrondissement are much engaged in the manufacture of sabots (wooden shoes) and other wooden wares, and of cotton yarn. They make also the best cheese of any in the Vosges.

DIEMEN'S LAND, VAN. [TASMANIA.]

DIEPPE, a town in France, on the coast of the Manche or English channel, at the mouth of a small river formed by the junction of the three streams, the Argues, the Bethaune, and the Eaulne; 92 miles in a direct line north-west of Paris, or 117 miles by the road through Meulan, Mantes, Vernon, Pont de l'Arche, and Rouen; in 49° 56' N. lat., and 1° 3' E. long.

In the ninth century the site of Dieppe was occupied only by a few fishermen's huts; in the eleventh century it had increased to a small town, under the name of Bertheville. Henry II., king of England and duke of Normandy,

erected, in 1188, a castle at Dieppe, which was demolished by his son Richard I. In the sixteenth century the fisheries, and especially the herring fishery, furnished its inhabitants with their chief occupation and wealth: their vessels went as far north as Schonen, in Sweden, to take the fish, which, after curing, they exported to the Mediterranean in their own vessels, called 'druggers,' because they brought back from the Levant spices and drugs. In the middle of the sixteenth century the Dieppoise undertook the expedition in which Canada was discovered, and in 1637 they formed the first French settlements on the banks of the Senegal. In 1694 the town was bombarded by the English, and, with the exception of the antient church, nearly destroyed.

The coast at Dieppe runs north-east and south-west, and the town extends about a mile along it, having the harbour at the north-east end, and the present castle near the south-west. The town was regularly rebuilt after the bombardment of 1694: the streets are tolerably wide, paved with round stones, without foot pavement, and the houses picturesque, built of brick and stone, with high slanting roofs. There are six *places* or squares and two churches, St. Jacques and St. Remy. The church of St. Jacques is of Gothic architecture, and was, for the most part, rebuilt in the 14th or 15th century; the architecture is richly ornamented, but not in the best taste. There are at Dieppe a theatre, assembly-rooms, and promenades; nearly seventy fountains adorn the streets, which are supplied by an aqueduct three miles long. The present castle is an irregular pile of considerable extent: when Expilly wrote (1763) it was furnished with artillery, and commanded the town and the roadstead: the town walls are yet standing, but Dieppe is not a place of strength. The port is sufficiently large and secure, but the entrance is narrow, and subject to be obstructed by the accumulation of sand. The entrance to the port is formed by two piers: vessels of more than 400 tons cannot enter. There is on the quay a crucifix, said to be the largest in France, and a light-house.

The population of Dieppe in 1832 was 16,016; but it has declined of late years; for Expilly (A.D. 1763) estimated it at 21,000, including that of the suburb of Pollet, to the east of the town. The men are chiefly engaged in fishing and navigation. In August the herring fishery is carried on upon the English coast and in the North Sea, and employs 60 to 80 vessels of 25 to 30 tons, and about 900 to 1200 men: in October it is carried on in 120 to 130 smaller vessels on the French coast: the fish caught in the August fishery are salted: those caught in the October fishery, which are of smaller size, are sent to Paris and the provinces to be eaten fresh. The mackerel fishery is carried on in decked boats of 20 to 50 tons, each manned with from 12 to 20 men, chiefly on the coast of Picardie. The vessels employed in the Newfoundland and other cod fishery are from 100 to 150 tons. The fisheries of Dieppe are not half so valuable as they were fifty years ago. Besides the persons actually engaged in them, these fisheries give employment to others engaged in boat-building, rope and sail making, and cooperage. Oysters are dredged on the banks opposite Dieppe, and there are beds in which the oysters of Granville and Cancale and Marennes, near Rochelle, are deposited. Lace-making was formerly carried on to a considerable extent; but this branch of manufacture has much declined. Trinkets in gold, horn, and ivory, are made, and pendulum clocks, at St. Nicolas, a village near the town. Dieppe has of late years risen into some repute as a bathing place. It has a high school and a royal school of navigation. Richard Simon, one of the Pères de l'Oratoire, and an eminent Hebraist and biblical critic, his nephew, Antoine Bruzen de la Martinière, compiler of 'Le Grand Dictionnaire Géographique Historique,' &c., and the celebrated French Admiral Du Quesne, were natives of Dieppe. (Dibdin's *Tour in France and Germany*; Mrs. Stothard's *Tour through Normandy*; Balbi; Malte Brun; Expilly.)

Dieppe is the capital of an arrondissement which contained, in 1832, 109,978 inhabitants.

DIERVILLA, a genus of Caprifoliaceous plants, consisting of a single North American species, by Linnæus considered a honeysuckle, and called *Lonicera Diervilla*. It is however obviously not of that genus, because its fruit is a dry capsule with a papery pericarp, with four cells and several seeds.

D. Tourneforti, or, as it is also called, *D. humilis, lutea*, or *canadensis*, is a common hardy shrub, growing from two

to three feet high, in a spreading manner, and having small funnel-shaped irregular five-cleft yellow flowers, growing in stalked clusters of two or three from the axils of opposite ovate serrated leaves. It is found wild in rocky woods in the United States, from Canada to Carolina, flowering in June.

DI'ESIS, in antient music (*διεσις, division*). The Greeks divided a tone into a major and minor semitone; the greater was called an apotome [APOTOME], the lesser a limma, or Diesis: to the difference between the two the name of comma [COMMA] was given. But it must here, once for all, be observed, that the Greek writers, if we really enter into their meaning, differ much in their definitions of musical intervals, and that the moderns are no less at variance in their interpretation of many antient terms of the art.

DIET. [FOOD.]

DIFFAREATION. [MARRIAGE.]

DIFFERENCE, the excess of one quantity over another. This fundamental meaning of the term is almost lost in the higher parts of mathematics, from the association of it with a methodized theory, derived from the consideration of the differences presented by successive quantities which follow a regular law. It is therefore a very wide branch of pure mathematics which must be considered under this term, namely, the method or calculus of differences. And the connection of this subject with the differential calculus (the results of the latter being, in one point of view, particular cases of the former) renders it impossible to treat of the two with that perfect separation which the alphabetical arrangement of a work like the present requires. Following the plan which we have laid down in other articles, we shall here describe the most important results connected with the term in question, referring for information on other matters to the following articles:—**INTEGRATION, FINITE; GENERATING FUNCTIONS, THEORY OF; EXPONENTS, NOTATION OF; SYMBOLS OF OPERATION AND QUANTITY, SEPARATION OF; EQUATIONS OF DIFFERENCES; INTERPOLATION.**

If we carry the hand along a sheet of paper, laying down points with a pen at various intervals, we get a number of points, through which an infinite number of curves may be made to pass: but generally speaking, there is one which is more simple than all the rest. If we also assign various numbers, we may conceive them all to be values of some function of a variable x , answering to $x = 1, x = 2, \&c.$ Thus we may ask the following question: what is that function of x of which 43, 47, 53, 61, 71, 83, &c., are the values, when x is successively made equal to 1, 2, 3, 4, 5, 6, &c.? This problem is indeterminate, with respect to common algebra merely, unless we can ascertain a law by which the series can be continued *ad infinitum*, and which it is allowable to assume: it then becomes determinate with respect to the expressions of common algebra only, but is again indeterminate if we are allowed to assume the transcendental expressions of trigonometry or the integral calculus. Confining ourselves to the expressions of common algebra, we may detect any law which prevails throughout the whole series by taking the difference between each term and the next, and thus forming a new series; and then by repeating this process again and again until the series so formed presents an easily perceptible law. Thus in the preceding case we have

Given series	43	47	53	61	71	83 ...
Series of {						
First differences	4	6	8	10	12	
Second differences		2	2	2	2	

We now see, that irregular as the first series may appear, the successive differences of the successive differences of its terms are always the same, and we may thus extend the series further. Thus we have—

83	97	113	131	151	173, &c.
12	14	16	18	20	22, &c.
2	2	2	2	2	2, &c.

But still this question remains; assuming the preceding law of continuation, and also that we have thus the values of some function of x answering to $x = 1$ (namely, 43), $x = 2$ (47), &c. What is the value of the function answering to fractional values of x , for instance when $x = 2\frac{1}{2}$? Considering that $x = 2$, gives 97, and $x = 3$ gives 113, it might

seem at first sight that $x=2\frac{1}{2}$ should give 105. But a moment's consideration will show that this can only be in the series

$$81 \quad 97 \quad 113 \quad 129, \&c.,$$

and that the irregularity of the progression from term to term will require a law to express it, such as will not allow of uniform progression between the terms. Such are the notions which might be made to suggest themselves, and the difficulties of which find their answers in the mathematical consideration of the subject.

Let any term chosen at pleasure in a series be called a , let the next term be a_1 , the next a_2 , and so on. That is, a_n means the n th term from a , not reckoning a . The succession of *first differences* (a more convenient way of expressing the *first succession* of differences) is—

$$a_1 - a, \quad a_2 - a_1, \quad a_3 - a_2, \quad a_4 - a_3, \dots$$

The succession of *second differences* (*second succession* of differences) is—

$$a_2 - a_1 - (a_1 - a), \text{ or } a_2 - 2a_1 + a \\ a_3 - a_2 - (a_2 - a_1), \text{ or } a_3 - 2a_2 + a_1, \&c.$$

The succession of third differences, similarly derived from the preceding, is—

$$a_3 - 3a_2 + 3a_1 - a, \\ a_4 - 3a_3 + 3a_2 - a_1, \&c.$$

From which it will be evident to any one who knows the binomial theorem and the law of its co-efficients, that the first term of the n th succession of differences is—

$$a_n - n a_{n-1} + n \frac{n-1}{2} a_{n-2} - \dots (n+1 \text{ terms}).$$

It is usual to denote this by $\Delta^n a$, the letter Δ standing for the operation of taking the difference, the exponent expressing that this operation has been repeated until it has been performed n times, and a being the term of the series used in the first operation. The symbol is called the n th difference of a .

If, then, we write the series and its successions of differences, not using the results of the operations, but their symbols, we have as follows—

$$\begin{array}{ccccccc} a & a_1 & a_2 & a_3 & a_4 & \dots & \\ \Delta a & \Delta a_1 & \Delta a_2 & \Delta a_3 & \dots & & \\ \Delta^2 a & \Delta^2 a_1 & \Delta^2 a_2 & \dots & & & \\ \Delta^3 a & \Delta^3 a_1 & \dots & & & & \\ & \&c. & & & & & \end{array}$$

From which we find that $a_1 = a + \Delta a$.

$$a_2 = a_1 + \Delta a_1 = a + \Delta a + (\Delta a + \Delta^2 a) \\ = a + 2\Delta a + \Delta^2 a$$

$$a_3 = a_1 + 2\Delta a_1 + \Delta^2 a_1 = a + \Delta a \\ + 2(\Delta a + \Delta^2 a) \\ + \Delta^2 a + \Delta^3 a$$

$$\text{or, } a_3 = a + 3\Delta a + 3\Delta^2 a + \Delta^3 a.$$

Proceeding in this manner, and by the assistance of the binomial theorem as before, we find that—

$$a_n = a + n \Delta a + n \frac{n-1}{2} \Delta^2 a + \dots (n+1 \text{ terms}).$$

These two theorems are the fundamental parts of the whole theory of differences; and our limits will not allow us to go further into the subject. We shall only observe, that it is most desirable that this very elementary branch of pure mathematics should be taught as a part of common algebra, or at least with the first rudiments of the differential calculus. The almost universal practice of deferring this subject until the student is master of the integral calculus, is entirely subversive of all natural order, and is perhaps one of the reasons why the differential calculus is proverbially difficult. Various developments and applications are to be found in every work on the subject.

The term difference is continental; the older English term was *increment*.

DIFFERENCE, ASCENSIONAL. [ASCENSION.]

DIFFERENTIAL CALCULUS, the name given by Leibnitz to the science which was digested nearly about the same time by himself and Newton, independently of each other [FLUXIONS, COMMERCIIUM EPISTOLICUM], and which

has of late years almost exclusively prevailed in this country, to the exclusion of the name, notation, and (so far as they differ) methods of Newton's fluxions.

It is impossible, in the smallest degree, to exhibit the present state and uses of a science into which all others merge as the student approaches the higher applications of mathematics. The article DIFFERENTIAL COEFFICIENT will, so far as it goes, give some idea of the nature of its first step; but the following remarks must be considered as intended for the student who has made some progress in a modern elementary work.

The history of the differential calculus, at its first rise, is so connected with that of the Newtonian FLUXIONS, in consequence of the celebrated dispute as to the right of invention, that we have thought it best to refer the whole point to the last-named article. On the history of the science since the time of Newton, there is no work from which we can trace out a connected account of the various steps by which the present system has been formed. In fact, most of the new investigations have been made with reference to some particular points of physical science. It would be very difficult to write the history of this calculus without entering at the same time into that of mechanics, optics, astronomy, &c. &c., and of every subject to which it has ever been applied. An attempt at the former without the latter would be an account of the progress of language without mention of literature, oratory, or the drama.

In the meanwhile, seeing that notions as to the most proper and useful basis on which to build this science are far from being fixed, the most advantageous course which we can here adopt is to give a short account of the various systems which have been proposed, referring to such articles and treatises as will enable the student to obtain further information. These different systems all produce the same results, expressed in very similar manners: there is no question between them as to the truth or falsehood of any one deduction, and a practised intellect can always see how the principles of any one, *assumed as granted*, may be made to furnish demonstration of those of any other. It is therefore, with some exception, a metaphysical rather than a mathematical difference which agitates (or rather which did agitate) the mathematical world. We do not mean to say that opinions are now agreed; but it seems that the question is left open, it being admitted that the manner in which a student arrives at his knowledge of the subject in the first instance is not of the greatest importance, provided that, when it has been obtained, he give his attention to the comparison of the various methods by which he might have attained the same end.

The precursors of Newton and Leibnitz, namely, Archimedes, Cavalieri, Wallis, Barrow, Fermat, Roberval, and others, touched so near upon the differential calculus, that it is obvious any of them might have taken the place of either of the first, if they had possessed more powerful means of algebraical development. After Vieta, Descartes, Wallis, and Newton (considered only as the discoverer of the binomial theorem), the step to a formal calculus was comparatively small. The essential part of the difficulty had been removed, and by much the greater part of the distance between Archimedes and Leibnitz had been gained. This point once attained, *methods* sprung up with rapidity, and in little more than a century we find the introduction of the various schemes which it will be necessary to mention, namely—Leibnitz's method of infinitesimals; Newton's method of prime and ultimate ratios; Newton's method of fluxions; Landen's method of vanishing fractions, or residual analysis; D'Alembert's method of limits; Lagrange's method of derivation.

Many other forms have been proposed, which either coincide in principle with one or other of the preceding, or are without any independent claim to notice. Several of the preceding, indeed, are more distinguished from each other by historical notoriety than by essential difference of character. If we distinguish carefully between the first principles of a method and the manner in which those principles are applied to algebra, it would not be any great stretch of assertion to contend that all the methods except the last are different ways of expressing the same fundamental ideas; and that the last (Lagrange's) is a proof that, so long as the preceding methods employed the usual amount of algebraical assumption in the establishment of the connection between themselves and algebra, that same

quantity of assumption would have been sufficient for the basis of a purely algebraical science, equivalent to the differential calculus.

The method of Leibnitz assumes that quantities are made up of infinite numbers of infinitely small parts. [INFINITESIMAL CALCULUS, INFINITE.] It is a sort of atomic theory of pure magnitude, which is most obviously either false or obscure; for so far as infinitely small quantities can be definitely explained, it is obvious that there are no such things; and any obscurity left in their definition extends itself throughout the whole science. But the falsehood of the supposition is not absolute; for though magnitudes cannot be distinctly laid down to be composed of an infinite number of infinitely small parts, yet any magnitude can be divided into a number of parts greater than any we may happen to name, each of which parts shall be less than any magnitude we may happen to name. Thus it is perfectly obvious that a foot may be divided into parts more than a million in number, each of which shall be less than the hundred millionth part of an inch. If we may use such a phrase, the falsehood of the assertion may be made of as small an intensity as we please, and the consequence is, that its results turn out absolutely correct. All the difficulties of the science are concentrated into one single assertion; and when this assertion is once fairly understood and received in a correct sense, all that follows is more easily understood and remembered, and far more easily applied, than the results of any other method. Whichever of the systems a student pursues, it is our decided opinion that he should accustom himself to translate every result into the language of the infinitesimal calculus, and endeavour to demonstrate it by the methods of the same. It is usual to give a chapter on this method in elementary works; in addition to which we should strongly recommend to the student of principles, Carnot, 'Réflexions sur la Méthode du Calcul Infinitesimal,' Paris, 1813: a work which has been translated into English. But it must be understood not to recommend the peculiar method of explaining the difficulties of infinitesimals adopted in this work, but only the manner of stating the points of difficulty, and the comparison of the different systems.

The system of Newton, known by the name of prime and ultimate ratios, was set forth in the first section of the Principia, and is the method pursued throughout that work. It is in reality a method of limits, exhibited in a form which allows of a more ready application to geometry than to algebra, and accordingly it is abandoned by Newton himself in the method of fluxions. Instead of considering and comparing simultaneous increments of infinitely small magnitude, the ratios of small but finite increments are taken; and not these exactly, but the limits towards which they approach when the increments are diminished, which are called *ultimate* ratios, or *nascent* ratios, according as the increments are supposed to be in the act of growing from or diminishing towards nothing. The expression of Newton will justify us in using the three words in Italics: 'Objectio est, quod quantitatum evanescentium nulla sit ultima proportio: quippe quæ, antequam evanuerunt, non est ultima; ubi evanuerunt, nulla est.... Similiter per ultimam rationem quantitatum evanescentium, intelligendam esse rationem quantitatum, non antequam evanescent, non postea, sed quâcum evanescent. Pariter et ratio prima nascentium est ratio quâcum nascuntur?' The student must seek for the account of this method in the first section of the Principia already cited, and in the article RATIOS, PRIME AND ULTIMATE. It may be observed that in illustrating the preceding answer, Newton appeals to the fundamental considerations on which his other method (if it be really another method) is founded, to which we now come.

The method of fluxions was also given by Newton, and with a peculiar notation, which maintained its ground in this country until about the year 1816. [FLUXIONS.] It will be seen in the articles DIRECTION, VELOCITY, FORCE, &c. that there are many fundamental ideas, connected with sensible objects, which lead to a practical differential calculus, and might have happened to have been the means of suggesting a strict and mathematical theory. Newton adopted one of these, that of velocity, of which it may be said that its assumption as an answer to objections is a formal evasion of all the metaphysical difficulties of the subject. Since the proportions of all quantities may be represented by those of straight lines, the nature of the comparative changes which take place in continuously in-

creasing or decreasing quantities may be referred to the velocities with which the terminal points of straight lines change their places. Velocity once clearly defined, in cases where it is variable, there is no further difficulty; but unfortunately a distinct conception of the measure of velocity is precisely equivalent to finding a meaning for the differential or fluxional coefficient independently of it. The theory of fluxions is best exhibited in the work of Maclaurin, 'Treatise on Fluxions,' 2 vols. 4to., Edinburgh, 1742, which, for rigorous and consistent application of its own principles, has, in our opinion, never been surpassed. It has the advantage of having been written in answer to acute objections of principle [BERKELEY], and is the work on fluxions.

The method of limits of D'Alembert, which is now more frequently used than any other, was considered by the author himself as an explanation of Newton's prime and ultimate ratios. It is usual to attribute the exposition of this method to D'Alembert (and, considered as a formal application of limits, correctly), though several, previously to him, had made special applications of the principle. The articles in the Encyclopædia must be considered as the *pièces justificatives*. The following article, DIFFERENTIAL COEFFICIENT, will explain this method, which contains the point in which the principles of all the preceding unite, and which must more or less be all. See also the article LIMIT.

The two remaining methods (those of Landen and Lagrange) are attempts to establish the science upon purely algebraical principles. Previously to entering upon them, we must remark that none of the preceding theorists attempted to make his system furnish any additional security to the methods of the algebra already in use. Such as it was, correct or incorrect, clear or obscure, no one gave a moment's consideration to the fact that algebra already contained difficulties of precisely the same character as those which were matter of dispute in the differential calculus. Taking it for granted that algebra stood already upon as firm a basis in every part as the differential calculus could ever, on any supposition, be expected to do, it was a matter of some interest to make the latter a pure extension of the former.

The residual analysis of Landen is a technically algebraical exhibition of the theory of prime and ultimate ratios. The tract in which it was promulgated, 'The residual Analysis, a new Branch of the Algebraic Art, &c.' appeared in 1764. When it is considered that this new branch of the algebraic art was only old fluxions in a different dress, the title may excite surprise, if we remember how well Landen deserved his reputation. But it must be remembered that all the discussion of which this article is meant to elucidate the history, arose from a tendency to consider two methods as *mathematically* different, which were not the same in the method of enunciating their first principles. A something between Landen and D'Alembert, as to principle, published in 1748, was called the 'Doctrine of Ultimators, containing a new Acquisition, &c., or a Discovery of the true and genuine Foundation of what has hitherto mistakenly prevailed under the improper names of Fluxions and the Differential Calculus.' The difference between Landen and Newton will appear in the article FRACTIONS, VANISHING, and in the instances which we shall presently give. It is the LIMIT of D'Alembert supposed to be attained, instead of being a *terminus* which can be attained as nearly as we please. A little difference of algebraical suppositions makes a fallacious difference of form; and though the residual analysis draws less upon the disputable part of algebra than the method of Lagrange, the sole reason of this is that the former does not go so far into the subject as the latter.

The method of Lagrange, first given in the public lectures at the *Ecole Normale*, and afterwards published separately under the title, *Théorie des Fonctions*, is a deduction of the whole science from Taylor's Theorem, which being absolutely granted, undoubtedly all the rest may be made to follow. If $\phi(x+h)$ can be always expanded in a form of which the two first terms are $\phi x + \phi'x \cdot h$, and if $\phi'(x+h)$ be related in the same manner to $\phi'x + \phi''x \cdot h$, and $\phi''(x+h)$ to $\phi''x + \phi'''x \cdot h$, and so on, it can be made to follow that

$$\phi(x+h) = \phi x + \phi'x \cdot h + \phi''x \cdot \frac{h^2}{2} + \phi'''x \cdot \frac{h^3}{2 \cdot 3} + \&c$$

upon principles as sound as those of algebra in the hands of Maclaurin, or Euler, or Clairaut, as elementary writers. It is our opinion that Lagrange has not been correctly understood, nor fairly dealt with, by those who have compared his theory of functions with the other methods. Undoubtedly any one who should maintain the unqualified admissibility of Lagrange's work must assert both the major and minor of the following syllogism.

Algebraical expansion (*théorie des suites* is Lagrange's phrase) as generally received A.D. 1790, was founded on sound principles: the *Théorie des Fonctions* is a logical and incontestable result of such algebra; therefore, &c.

All the attacks upon Lagrange have denied the major of this syllogism, whereas it appears to us that he never intended to assert more than the minor. Perceiving that the mathematical world was in the habit of calling in the aid of limits or infinitesimals, to help a *certain algebra* in deducing certain conclusions, he showed them how that very algebra, good or bad, was competent to the deduction of the same conclusions without either limits or infinitesimals; and he was correct. Notwithstanding any thing in the work in question, Lagrange might have admitted all that we shall find it necessary to say against his system, absolutely considered, in the article FUNCTIONS, THEORY OF.

A new question has arisen of late years, namely, whether the theory of limits be not absolutely necessary to the rigorous development of common algebraical forms, and whether this same theory of limits may not be applied to the establishment of the differential calculus, independently of any expansion. A tract of M. Ampère (as we believe), entitled '*Précis du Calcul Différentiel, &c.*' is the earliest writing we are acquainted with in which this is attempted to be done. A treatise on the subject, in process of publication by the Society for the Diffusion of Useful Knowledge, professes to have the same end in view. The work of M. Cauchy has much in it by which this object is promoted, but expansion is avowedly introduced.

We shall now state two propositions, one geometrical, the other algebraical, in the words of the several systems.

Infinitesimals.—An infinitely small arc of a circle is equal to its chord.

Prime and ultimate Ratios.—If an arc of a circle diminish, the ultimate ratio which it bears to its chord is one of equality; or, if it begin to increase from nothing, the prime or nascent ratio of the arc and chord is that of equality. Or the arc is *ultimately* equal to its chord.

Fluxions.—If an arc increase from nothing with a uniform velocity, the velocity with which the chord increases is, at the first moment, equal to that of the arc.

Limits.—If the arc of a circle (and therefore its chord) diminish without limit, the limit of the ratio of the arc to the chord is one of equality.

Residual Analysis.—When the arc of a circle = 0

$$\frac{\text{arc}}{\text{chord}} = \frac{0}{0} = 1$$
 which is ascertained by clearing the numerator and denominator of a factor which vanishes when arc = 0.

Theory of Functions.—When the arc is expanded in the following series,

$$\text{Arc} = A \times \text{chord} + B \times (\text{chord})^2 + \&c.$$

then $A = 1$.

Infinitesimals.—If an infinitely small increment dx be given to x , then x^3 receives the infinitely small increment $3x^2 dx$.

Prime and Ultimate Ratios.—The ratio which any increment given to x bears to the consequent increment of x^3 is ultimately that of 1 to $3x^2$.

Fluxions.—If x be a line which increases with a velocity $\dot{x}$, then x^3 increases with the velocity $3x^2 \dot{x}$.

Limits.—The limit of the ratio obtained by dividing an increment of x^3 by the increment of x which produced it, on the supposition that the latter increment diminishes without limit, is $3x^2$.

Residual Analysis.—Since

$$\frac{y^3 - x^3}{y - x} = x^2 + xy + y^2$$

it follows that when $y = x$ $\frac{x^3 - x^3}{x - x} = 3x^2$.

Theory of Functions.—If $(x + h)^3$ be expanded in a series of powers of h , the coefficient of the first power of h is $3x^2$.

DIFFERENTIAL COEFFICIENT. The expressions to which this term is applied are of a degree of importance in the science to which they belong, as great as that of the letters of the alphabet in writing. Without entering into the method of using them, which would be in effect to write a treatise on the differential calculus, we shall make some remarks on the manner of defining and understanding the term.

When two magnitudes are so related that either being given the other is also given, it follows that any change being made in the one, the consequent change in the value of the other can be found, and the two changes can be compared as to magnitude. By this means a rough notion can be formed as to the effect which a change of value in one produces in the other. In such articles as CURVATURE, DIRECTION, VELOCITY, FORCE, &c., it is sufficiently shown that this rough notion, obtained by making a sensible change in one magnitude and comparing it with that produced in another, though sufficient for practical purposes, does not afford any exact and mathematical measure of the thing sought for. In each of the articles cited, it is found necessary to diminish the change originally supposed without limit, and it is not the actual ratio of two changes which we have to consider, but the limit to which that ratio approximates as the changes are diminished without limit. We must distinctly refer the student to sensible objects for an illustration of the cause why it is convenient, and even necessary, to have recourse to the *limit of a ratio*. [See also LIMIT, RATIOS (PRIME AND ULTIMATE), and various articles cited in DIFFERENTIAL CALCULUS.]

Let ϕx be a function of x , called y , which when x is changed into $x + h$, becomes $y + k$, so that

$$k = \phi(x + h) - \phi x.$$

Divide k by h , ascertain the limit towards which this quotient approximates when h is diminished, and that limit is what is called the differential coefficient of y with respect to x . For instance, let $y = x^2 + x$; then

$$\begin{aligned} k &= (x + h)^2 + (x + h) - (x^2 + x) \\ &= 2xh + h^2 + h; \end{aligned}$$

and k divided by h gives $2x + h + 1$, which, when h is diminished without limit, has for the limit of its decrease, $2x + 1$, which is therefore the differential coefficient of $x^2 + x$ with respect to x .

The term *differential coefficient* arises thus. The method of Leibnitz [INFINITESIMAL CALCULUS] proceeds as follows. Imagine x in the preceding expression to be increased by an *infinitely small quantity* (see article just cited for remarks on this phrase) which call dx , the *differential* of x . Then the resulting differential of y is

$$\begin{aligned} dy &= (x + dx)^2 + (x + dx) - (x^2 + x) \\ &= (2x + 1) dx + (dx)^2 \end{aligned}$$

Now $(dx)^2$ is rejected as being an infinitely small part of the preceding term, so that $(2x + 1) dx$ is the *differential* of $x^2 + x$. The expression $2x + 1$ (which is our preceding result) is here the *coefficient* of the *differential* dx , and when a less objectionable method of obtaining it came into use, still retained the name of differential coefficient. It were exceedingly to be wished that some shorter term could be agreed on for the expression of a result which is so often required to be named.

In the method of Leibnitz the differential coefficient is actually dy divided by dx , and it is still expressed by $\frac{dy}{dx}$ in the more modern methods. But this notation must

now be supposed to be obtained as follows. Let the change of x into $x + \Delta x$ be accompanied by that of y into

$y + \Delta y$; then $\frac{\Delta y}{\Delta x}$ expresses the algebraical ratio of the

change of y to the change of x . In making the convention that $\frac{dy}{dx}$ is to stand for the limit of $\frac{\Delta y}{\Delta x}$, obtained from the

supposition that Δx diminishes without limit, we consider the first symbol, not as that of an algebraical fraction, but as one whose *whole* has a meaning, the *parts* having none. This is the case with all *simple* symbols, as distinguished from *compound* symbols: thus in the figure V, standing for five, the two sides of the letter have no independent meaning; while in $4 + 7$, each of the three symbols, 4, +, and 7, has meaning contributing to that of the whole, and at the same time independent of it. Thus

though we consider $\frac{dy}{dx}$ as pointing out that it is y which has been differentiated, and with respect to x , we do not, in this symbol, assign to dy and dx any independent share of meaning.

The advantage of the notation in question is the connexion which it preserves between the practical use of the method of Leibnitz, and the theoretical accuracy of that of limits. For instance, it is strictly true, according to our conventions, that

$$\text{when } y = x^2 + x, \quad \frac{dy}{dx} = 2x + 1:$$

but, giving dy and dx separate meaning, it is *not* true that $dy = (2x + 1) dx$. Yet the latter equation, though never true, is of this kind, that it may be made as near to truth as we please, if dx may be made as small as we please. For the reason why it cannot therefore be said to be true in the case where $dx = 0$. [FRACTIONS, VANISHING.]

The differential coefficient of a differential coefficient is called the *second* differential coefficient; a repetition of the process gives the third differential coefficient: and so on. These, if the original method of notation were proceeded with, should be represented by

$$\frac{dy}{dx}, \quad \frac{d\left(\frac{dy}{dx}\right)}{dx}, \quad \frac{d\left(\frac{d\left(\frac{dy}{dx}\right)}{dx}\right)}{dx}, \text{ \&c.}$$

but a more convenient notation is derived as follows. Let the substitution of $x + \Delta x$ for x take place any number of times in succession, giving

$\phi(x), \phi(x + \Delta x), \phi(x + 2\Delta x), \phi(x + 3\Delta x), \text{ \&c.}$

Form the successive differences of the first term [DIFFERENCE] ϕx or y : then the following theorem can be proved. The n th difference of y , or $\Delta^n y$, divided by the n th power of Δx , or $(\Delta x)^n$, is an expression of which the limit, made by diminishing Δx without limit, gives the same result as arises from differentiating y , n times in succession. We may therefore (subject to the remarks already made on the

first coefficient) represent the limit of $\frac{\Delta^n y}{(\Delta x)^n}$ by $\frac{d^n y}{(dx)^n}$, so that the function y and its successive differential coefficients are denoted as follows:—

$$y, \quad \frac{dy}{dx}, \quad \frac{d^2 y}{dx^2}, \quad \frac{d^3 y}{dx^3}, \quad \frac{d^4 y}{dx^4}, \text{ \&c.}$$

It is usual to omit the brackets in the denominators.

DIFFERENTIAL EQUATIONS. [EQUATIONS, DIFFERENTIAL.]

DIFFERENTIAL THERMOMETER, \&c. [THERMOMETER, DIFFERENTIAL, \&c.]

DIFFLU'GIA. [POLYPIARIA DUBIA.]

DIFFRACTION OF LIGHT. The peculiar modifications which light undergoes when it passes by the edge of an opaque body are classed as phenomena of the *diffraction* or *inflexion* of light.

When a ray of solar light is transmitted through a very small hole in a card, or is collected in a point by means of a double convex lens, and then diverges from that point, if a small opaque plate of any outline be interposed in the course of the ray, the shadow of this object received on a parallel screen behind will be encompassed by a series of coloured bands or fringes of a similar outline with the body, except at its angular points; the order of the colours in each fringe, reckoning from the outside towards the shadow, or inside, is, as in the prismatic spectrum, from red to blue, but the intermediate colours are less distinctly isolated, partaking of a mixture of the extreme tints.

The actual shadow, or dark space within the innermost fringe, is also larger than the geometrical shadow which would have been cast if the rays had passed exactly by the edge of the body in straight lines and been received on the same screen; the space by which the actual shadow surpasses the geometrical in breadth, is independent of the linear dimensions, the form or the matter of the interposed body, and it will therefore be most sensible in very narrow bodies: hence arise the dilated shadows of hairs, threads of webs, \&c. which must fall daily under every one's observation.

When the interposed body is very narrow but of sensible width, streaks alternately brighter and darker will be found

within the shadow, and a white line along the middle, when the body is of a long and slender rectangular form.

If the incident light were homogeneous, such as pure red, blue, \&c. as found in the spectrum, the colour of the fringes though differing in intensity from one another, would of course be the same as the incident, but the sun's light, and most artificial light, being compounds of several simple coloured lights, the fringes in such case are of various tints which predominate on their external or internal limits, according as they are differently subject to the causes which produce diffraction.

Sir I. Newton in his optics relates several modes in which he varied the experiments on the inflexion of light; when two perfectly straight knife-edges were made to meet at a very acute angle, the fringes formed between the shadows of the knives received on a screen at a considerable distance from them were hyperbolas, each having for asymptotes the shadow of the corresponding knife-edge and a right line perpendicular to that bisecting the acute angle and passing through the intersection of the shadows; they approached to rectangular hyperbolas as the inclination of the edges diminished, and mutually crossed without interfering, the points where they crossed being however differently placed as the screen was removed to different distances.

In his queries, he suggests an explanation that light may be subject to the action of forces sensible only at very small distances from the surfaces of bodies, that under their influence the rays in their course near the edge of the body, instead of passing straightforward, describe very sinuous paths, with many contrary flexures, and thus they are found some turned inwards towards the shadow, others outwards, forming coloured bands; the curve surface, which is the locus of the intersections of all these diffracted rays, forming the envelope of the visible shadow.

Objections have been taken to this theory, on the ground that the phenomena will vary when the positions of the object and screen being fixed, that of the luminous point is varied, and also that a force emanating from the body ought to be supposed variable with its density; these objections do not appear to the writer of this article of great weight. In the former case, the divergence of the pencil of rays within the sphere of action of the forces is altered *ab initio*; in the latter the superposition of two similar material systems of particles, though doubling the force, when effective, would leave all the points of evanescence of the force unchanged, would leave the asymptotes unchanged, and it does not at all appear necessary that it should alter any phenomena of which the limits are unvaried.

Explanations however are not wanting on the undulatory hypothesis of light, and Fresnel has with considerable simplicity, calculated the positions and breadth of the fringes merely as resulting from the propagation of the undulations of a whole wave of light, minus that portion of a wave surface subtending the same solid angle, at the origin of the wave, as the obstacle.

Dr. Young, by a very simple expedient, has converted Grimaldi's experiment relative to the light streaks within the shadow of a long rectangular body, into the basis of his very beautiful theory of interferences. Let the light at one edge of the body be altogether stopped by an intercepting body placed before or behind the rectangular one, while the light is allowed free passage as before at the other side; the streaks will notwithstanding be instantly obliterated, showing that those streaks are produced by the interference of waves passing on either side of the body, and having their length either equal or differing by a small multiple of the length of an undulation.

Many beautiful optical phenomena arising from diffraction have been produced by transmitting light through one or several small holes, or the interstices of fine wire work, and even by reflection between plane mirrors inclined at a very small angle. Persons desirous to be further acquainted with these phenomena may consult the memoirs of Young, Fresnel and Fraunhofer; some interesting facts on the same subject have also been supplied by Sir J. Herschel in his treatise on light.

DIGAMMA, or VAU, is the name given by grammarians to a letter which once belonged to the antient alphabet of the Greeks. It appears to have occupied the sixth place in that alphabet, for while *epsilon* is employed as the numerical symbol for five, the next letter, as that alphabet is now arranged, is the representative of seven. Moreover, this position of the digamma will correspond precisely with that

of *vau* or *waf* of the Hebrew, and of *f* in the Latin alphabet, two letters of kindred power and form. A further argument may be found in the principles which would seem to have determined the arrangement of the Greek alphabet. [ALPHABET, p. 380, col. 2.] The letter is still to be seen in many inscriptions. (ALPHABET, p. 383, plate ii., Nos. 20, 21, and 26.) With regard to the power of the letter, it is now the general and well-established opinion that it is equivalent to our own *w*.

The use of the digamma prevailed more particularly in the Æolic dialect of the Greek tongue. In the other dialects it was commonly dropped, particularly the Attic; and as this became the favourite dialect of Grecian literature, the digamma at last escaped from the alphabet; and even the Homeric poems, which had been written in a dialect still possessing the digamma, were presented to the Athenians without that letter, to the serious injury of the metre. But though the form of the digamma was not admitted into the Attic alphabet, the vowel *o* was occasionally used, so as virtually to represent it, as in *οἶδα*, *οἶκος*, *οἶνος*, equivalent to *FIΔA*, *FIKOΣ*, *FIHOΣ* (comp. the Latin *video*, *vicus*, *vinum*); and it was altogether superfluous to prefix the digamma, *FOIKOΣ*, as was sometimes done. At other times the *upsilon* filled the place of the digamma, as in the nouns which terminate like *βασιλευς* (*BAΣIAEΦΣ*.)

The Latin language, being more closely connected with the Æolic dialect of the Greek, is abundant in the use of this letter; for the true pronunciation of the *v* or *u* consonans must have been the same as our *w*, or it could not have so readily interchanged with the vowel *u*. The Greek words *ων*, *εαρ*, *εσπερος*, *εστια*, *ιον*, appear in Latin as *ovum*, *ver*, *vesperus*, *vesta*, *viola*. In the last instance indeed there are two other points of difference, the Latin word being feminine, like *rosa* compared with the Greek *ῥόδον*; and secondly, a diminutive, which is well suited to the size of the flower. Sometimes a *b* appears in the Latin word, where the Æolic Greek must have had the digamma, as *probus* compared with *πρᾶυς*; or an *f*, as *Formiæ* compared with *Orniæ*.

The disappearance of the digamma in one dialect and its retention in another is in perfect accordance with what is seen in modern languages. In our own we have ceased to pronounce the *w* in *who*, *whose*, *two*, *sword*, *answer*, *whole*; while in *one* and *once* we have the sound without the character, and yet drop it again in *only*. The Danish dialect of the Teutonic language is remarkable for throwing off the *w*, thus *word* in the mouth of a Dane is *ord*.

For the assertions of the grammarians and the opinions of the learned with regard to the digamma, see Kidd's edition of Dawes's *Miscellanea Critica*, pp. 175-335. The editor has given a list of the Greek words which he supposes once to have possessed this letter.

DIGBY, EVERARD, was born in 1581, of an antient, honourable, and wealthy family. His father, who was a Roman Catholic, and a man reputed for learning, died in 1592, leaving the estates at Tilton and Drystoke in Rutlandshire to his son, the charge of whose education he had committed to some priests of his persuasion. In 1596 Everard married the only daughter and heiress of William Mulsho or Moulsoe of Goathurst in Buckinghamshire, whose parents dying soon after the marriage, he acquired a large estate in right of his wife. In 1603 he was knighted by James I. at Belvoir Castle, which the king visited in his journey from Scotland to London to take possession of the throne.

The share which Sir Everard Digby took in the Gunpowder Plot is the sole cause of his celebrity. This conspiracy was projected when he was twenty-four years old: the oath of secrecy was administered, and the design communicated to him by Catesby about Michaelmas, 1605. When Digby first heard of the plot he was averse to it, but forbore to reveal it on account of his oath: afterwards, when he found that it was approved by Roman Catholic priests, the religious scruples which he had entertained were removed, and he united cordially in the project, contributing towards its execution a quantity of horses, arms, and ammunition, together with 1500*l.* in money. Digby was not concerned in the preparation of the vault; the share of the plot that was allotted to him was to assemble a number of the Roman Catholic gentry on the 5th of November, at Dunchurch in Warwickshire, under the pretence of hunting on Dunsmoor Heath, from which place, as soon as they had received notice that the blow was struck, a party was to be

despatched to seize the Princess Elizabeth at the house of Lord Harrington, near Coventry. The princess was to be immediately proclaimed queen in case of a failure in securing the person of the prince of Wales or the young duke of York, and a regent was to be appointed during the minority of the new sovereign. Digby assembled his party, and rode to Lady Catesby's at Ashby Ledgers to hear the result of the scheme. In the evening five of the party arrived, fatigued and covered with dirt, with news of the discovery of the plot and the apprehension of Fawkes. A short consultation was held as to what was best to be done; and it was agreed to traverse the counties of Warwick, Worcester, and Stafford into Wales, where it was thought that they should find many adherents, exciting, as they went along, the Roman Catholic gentry to join them in a general insurrection. They carried off fresh horses in the night by stealth from the stable of a breaker of cavalry horses in Warwick; they seized arms at Lord Windsor's residence at Whewell; and on the 7th occupied a house at Holbeach belonging to Stephen Littleton. But all hope of accession to their numbers was at an end. 'Not one man,' says Sir Everard Digby in his examination, 'came to take our part, though we had expected so many.' The Roman Catholic gentry drove them from their doors, reproaching them with having brought ruin and disgrace on the Catholic cause by their ill-advised enterprise; while the common people stood and gazed upon their irregular train, and evinced anything but a disposition to join them. Sir Everard Digby forsook his companions at Holbeach, with the intention, as he stated, of hastening some expected succours: he was overtaken at Dudley, apprehended, and conveyed to London. On Monday, the 27th of January, 1605-6, he was tried, with his fellow-conspirators. No doubt of their guilt was entertained; though written depositions only were given in by the prisoners, and no witness was orally examined: Digby alone pleaded guilty. They were executed on the following Thursday. Sir Everard Digby has been described by Greenway as profound in judgment, and of a great and brilliant understanding: but we distrust this partial writer; he appears throughout this transaction rather as a weak and bigoted young man, never acting upon his own judgment or impulses, but submitting himself entirely to the control and guidance of the Jesuits. (Abridged from the *Library of Entertaining Knowledge*, 'Criminal Trials,' vol. ii.)

DIGBY, KENELME, the son of Sir Everard Digby, was born in 1603, three years before his father's execution. He was educated in the Protestant faith, and sent to Oxford at the age of fifteen, having been entered at Gloucester Hall. His ability was early apparent, and when he left the university in 1621 with the intention of travelling, he had acquired considerable reputation. After having spent two years in France, Spain, and Italy, he returned to England in 1623, and was knighted at Lord Montague's house, Hinchinbroke, near Huntingdon, in October in the same year. Under Charles I. he was a gentleman of the bed-chamber, a commissioner of the navy, and a governor of the Trinity House. In 1628 he obtained the king's permission to equip, at his own expense, a squadron, with which he sailed first against the Algerines, and afterwards against the Venetians, who had some dispute with the English. His conduct as a commander was creditable to him. Upon the death of Dr. Allen of Gloucester Hall in 1632, Sir Kenelme Digby became possessed of a valuable collection of books and manuscripts, which were bequeathed to him by his former tutor. The religious principles that he had imbibed under this learned man could not have been deeply rooted; for when Digby returned to France he was converted to Catholicism (1636), the religion of his parents. His conversion was the subject of a long correspondence with Archbishop Laud, who had always taken an interest in Digby on account of his unusual ability and learning.

He returned to England in 1638. On the breaking out of the civil war, he was imprisoned as a Royalist in Winchester House: during his confinement he wrote a refutation of Brown's '*Religio Medici*,' which occupied him until the petitions made by the queen of France for his relief were granted, and he was allowed to retire to that country. At Paris he was kindly treated by the court: and he became familiar with the celebrated Descartes, and associated with the principal men of learning. When the Royalist party had broken down, and had ceased to be formidable, Digby went home to England, with the intention of residing upon his estate, but the parliament hearing of his return, forbade

him the kingdom under penalty of death. The cause of this severity was the zeal that his eldest son had shown in the king's service, when, in 1648, with the duke of Buckingham and others, he made a stand near Kingston in Surrey. Young Digby was afterwards killed by Colonel Scroop in Huntingdonshire. Sir Kenelme now again travelled in France and Italy, and was everywhere received as a man of extraordinary merit. In 1655 his personal affairs required his presence in England; and during his stay, his frequent attendance at the Protector's court was in no small degree inconsistent with his prior conduct. The feelings which had led him to fight the duel in which he killed Lord Mount le Ros, because he had drank Charles's health as the 'arrantest coward upon earth,' must have now been totally obliterated. During a subsequent residence in the south of France he read many papers on different philosophical questions before literary societies, of which he was a member. This course he afterwards followed in England, whither he returned in 1661, and passed the remainder of his life. He died of the stone in 1665. Sir Kenelme Digby married Venetia Anastasia Stanley, daughter of Sir Edward Stanley of Tongue Castle in Shropshire. This lady was more celebrated for her beauty than her virtue. Before her marriage she had borne more than one child to her lovers, among whom was the duke of Dorset, who had settled 500*l.* a year upon her. Sir Kenelme showed great anxiety to preserve her beauty: he invented cosmetics for that purpose, and made her the subject of several strange experiments. There are pictures of her by Vandyke, one of which is now in Windsor Castle. She died suddenly, leaving one son by her husband.

Sir Kenelme Digby, though he fell into the errors of philosophy and many of the wild dreams which were common in his day, was certainly possessed of no ordinary talents: for his character we must refer our readers to Lord Clarendon (*Life*, vol. i., p. 34), who has ably described it. The following is a list of his writings:—'A Conference with a Lady about the choice of a Religion,' Paris, 1638; 'Letters between Lord George Digby and Sir Kenelme Digby concerning Religion,' Lond. 1651; 'Observations on Religio Medici,' Lond. 1643; 'Observations on part of Spenser's Fairy Queen,' Lond. 1644; 'Treatise on the Nature of Bodies,' Paris, 1644; 'A Treatise on the Soul, proving its immortality,' Paris, 1644; 'Five Books of Peripatetick Institutions,' Paris, 1651; 'A Treatise of adhering to God,' Lond. 1654; 'Of the Cure of Wounds by the Powder of Sympathy,' Lond. 1658; 'Discourse on Vegetation,' Lond. 1661. Sir Kenelme Digby's valuable library, which had been removed to France at the out-breaking of the civil wars, became, on his death, by Droit D'Aubaine, the property of the French king.

DIGEST. [CORPUS JURIS; JUSTINIAN'S LEGISLATION.]

DIGESTION, the process by which the food is converted into nutriment. Taken in its whole extent the process of digestion comprehends the entire series of changes by which the crude aliment is assimilated into arterial blood. These changes are effected by organs which viewed collectively, comprise a most extensive apparatus commencing at the mouth and ending at the lungs.

The first changes upon the food are effected in the mouth where it is mixed with mucus and saliva. Torn to pieces by the teeth in the operation of mastication and softened by the secretions of the mouth until it is reduced to a pulp, it is then collected by the tongue and formed by that organ into a mass called a bolus. The bolus of food thus prepared is carried by the tongue to a muscular membranous bag called the pharynx, situated at the back part of the throat. The pharynx as soon as it receives the bolus contracts firmly upon it, and by a proper muscular action delivers it to the œsophagus, a long muscular tube which extends from the pharynx to the stomach. The bolus of food does not descend along the œsophagus by its own weight, for a person can swallow while standing on his head, and many animals have obviously to convey their food along the œsophagus against gravity. The food when it enters the œsophagus is transmitted along the tube by a powerful contraction upon it of the strong fasciæ of muscular fibres of which it is composed.

By the œsophagus the food is conveyed into the stomach where it is converted into a fluid termed chyme. The chyme when duly prepared in the stomach is transmitted to the small intestines, in the first portion of which it is converted into a new substance called chyle. In its

passage along the second portion of the small intestines the chyle disappears, being taken up by a set of vessels named lacteals, which convey it through a double series of glands called the mesenteric glands, to the thoracic duct. By the thoracic duct it is conveyed through the abdomen into the thorax, where it is poured into one of the large veins, the subclavian, which returns the blood from the upper parts of the body to the right side of the heart to be, by the right heart, propelled into the pulmonary artery. By the pulmonary artery the chyle now mingled with venous blood is conveyed to the lungs, where it undergoes its ultimate change and is converted into arterial blood. 'The large intestines meantime carry out of the body that portion of the food which has not been converted into chyle.

The structure of the different parts of the extensive apparatus concerned in carrying on this series of changes, a structure fitting them in the most admirable manner for performing the specific offices assigned them, will be described under the names of the respective organs; at present we shall confine ourselves strictly to an account of the phenomena of digestion.

The food torn, as has been stated, into minute fragments by the operation of mastication, softened and brought into the state of a pulp by its admixture with mucus and saliva, and raised nearly to the temperature of the blood by the warmth of the mouth, is received into an extensive chamber, the stomach, where it is constantly maintained at a temperature of 100° of Fahrenheit, and kept in a state of gentle but almost unceasing agitation by a peculiar motion of the stomach, effected by its muscular fibres and called from its striking resemblance to the motion of the earthworm, peristaltic. The essential phenomena which take place on the introduction of the food into the stomach are the following.

The food on entering the stomach is not arranged indifferently in any part of the chamber, but is detained in the great extremity, or that portion of the stomach which is near the entrance of the œsophagus, termed the cardiac extremity. This portion of the stomach during the actual process of digestion appears to be cut off from the rest by a contraction of the circular fibres of the muscular coat, called the hour-glass contraction, by which about a third of the length of the stomach towards its small or pyloric extremity is separated from the great or cardiac extremity. The food received in the cardiac extremity is slowly dissolved; this solution takes place at the surface; 'in proportion as it proceeds the dissolved part is rolled off the rest by the peristaltic action of the fibres of the stomach and carried to the pyloric portion,' where it accumulates. Thus the undissolved and the dissolved portions of the food are in different parts of the stomach; the undissolved portion in the cardiac, and the dissolved portion in the pyloric extremity.

A remarkable change takes place on the inner or mucous surface of the stomach, the moment a portion of food comes in contact with it. This change has been seen to take place in the stomachs of animals, laid open during the process of digestion for the purpose of affording an opportunity to observe the phenomena, and even in the human stomach, which, in more than one instance, has been completely exposed to view in consequence of wounds accidentally inflicted. The mucous coat of the stomach, which is of a pale pink colour when the stomach is empty, becomes of a bright red colour when excited by the contact of food. Over this reddened surface are visible, more especially when it is examined through a magnifying glass, innumerable minute lucid points, from which distils a pure limpid and colourless fluid. This fluid, as it is discharged, is absorbed by the aliment in contact with the surface of the stomach, or collects in small drops and trickles down the sides of the stomach to the more depending parts, and there mingles with the food and dissolves it. This fluid, the true solvent of the food, is termed the gastric juice. It has been ascertained to be the efficient agent in digestion, and its solvent power has been demonstrated by a series of most decisive experiments long ago performed by Spallanzani and others. This distinguished physiologist swallowed a metallic tube perforated with holes and filled with flesh; he allowed the tube to remain in the stomach four hours, and then contrived to throw it up by exciting vomiting mechanically. The flesh in the tube was found to be thoroughly soaked with the fluid of the stomach; its surface was in a dissolved state, being soft and gelatinous,

and moreover it had wasted from fifty-three to thirty-eight grains. Subsequently Dr. Stevens induced a person practised in swallowing pebbles, to swallow a hollow silver sphere, containing raw or cooked flesh, or vegetables, and perforated with holes that would admit a crow quill; the sphere was voided in about forty hours perfectly empty. Next Mr. Hunter observed that the great extremity of the human stomach is sometimes found after death in a softened state and even in a state of partial solution, the coats of the stomach being dissolved by its own gastric juice and the edges of the opening appearing pulpy, tender and ragged, and even the parts adjacent to the stomach, as the spleen, the diaphragm, and the lungs, being in like manner softened.

This solution of the food is wholly different from the spontaneous resolution which warmth and moisture tend to produce in it. Exposure of the food to warmth and moisture decomposes it by the process of putrefaction; but the gastric juice is antiseptic, and stops the putrefying process even after it is considerably advanced. The solution of the food by the gastric juice is a chemical operation, and the gastric juice is a chemical agent, the exact nature of which is now clearly ascertained. Spallanzani discovered that the gastric juice is of an acid nature. Some years ago Dr. Prout ascertained that this acid is the muriatic. Dr. Prout's experiments were repeated by some distinguished chemists in France with different results; but the accuracy of Dr. Prout's conclusions was afterwards confirmed by the experiments of Tiedemann and Gmelin, and they have received a fresh confirmation by the more recent experiments of Bracconnot and Blondelot, so that it may be now considered as established that the agent by which the solution of the food in the stomach is effected is muriatic acid or chlorine. If meat and gastric juice be enclosed in a glass tube, and kept at the temperature of the human body, a product is obtained closely resembling the fluid formed by the solution of the food in the stomach. If meat be enclosed in a glass tube with dilute muriatic acid, and kept at the temperature of the blood, a perfectly similar product is obtained.

The muriatic acid constituting the essential ingredient of the gastric juice is conceived to be derived by an act of secretion from common salt, muriate of soda, contained in the blood. The alkali, the base of the salt, is retained in the blood to maintain the alkaline condition essential to its healthy constitution, while the acid is liberated and poured, in the form of gastric juice, into the stomach to accomplish the solution of the food.

After the food has undergone the action of the gastric juice, it loses its sensible properties, and is converted into the homogeneous semi-fluid mass which has received the name of chyme. Specific differences are distinguishable in chyme, according as the food from which it is formed has consisted of vegetable or animal matter, and according as it has contained fatty or oily substance, or has been destitute of them. Usually however it consists of a pultaceous mass, of a greyish colour; it has a sweetish taste, and is slightly acid. The character common to it, from whatever kind of food it may have been produced, and therefore distinctive of it, is its acidity.

Gradually as it is formed, the chyme accumulates in the pyloric extremity of the stomach. When the accumulation amounts to a certain quantity, the pylorus relaxes, and allows the chyme to flow from the stomach into the first portion of the small intestines, the duodenum. Here it is mixed with the mucus of the intestines, with the pancreatic juice, and with the bile. The bile slowly and at intervals, a drop about twice in a minute, flows into the duodenum, and diffuses itself over the neighbouring surface. On coming in contact with the chyme, the bile imparts to it its sensible qualities, its colour and bitterness. But in a short time a spontaneous change takes place in the chyme. It separates into a whitish tenacious fluid termed chyle, and into a grey pulp: the first is the nutritive part of the food, the second is its excrementitious portion. If fat or oil, whether of vegetable or animal matter, have formed part of the aliment, the chyle is of an opaque white colour; if not, it is of a greyish colour. It differs in its chemical character from chyme; for chyme is acid: chyle, on the contrary, is alkaline.

The chyle, together with the excrementitious portion of the food, is slowly transmitted along the small intestines. The progress of the chyle is rendered slow, partly by its own tenacity, in consequence of which it adheres with some

degree of firmness to the villi, and its progress is still farther retarded by the *valvulae conniventes*, which act as partial valves. [INTESTINES, SMALL.] In its course through the small intestines the chyle gradually disappears, being absorbed by the lacteal vessels, so called from the milk-like fluid they contain. The lacteals commence by open mouths on the surface of the villi. [LACTEALS.] Loaded with chyle, the lacteals penetrate the coats of the intestine, pass between the layers of the mesentery [MESENTERY], and enter the first order of mesenteric glands. In the mesenteric glands the lacteals unite freely with each other, and become exceedingly convoluted. On emerging from these glands the lacteals pass, still between the layers of the mesentery, on to the second order of mesenteric glands, which they enter, and in which they present the same convoluted appearance as in the first order. On emerging from the second order of mesenteric glands, the lacteals pass on to the receptacle of the chyle, which forms the commencement of the thoracic duct. [THORACIC DUCT.] In the receptacle of the chyle terminates another system of absorbent vessels, termed lymphatics, from the colourless and pellucid fluid, called lymph, which they contain. From the receptacle of the chyle, the chyle and lymph commingled flow into the thoracic duct, by which tube they are transmitted through the abdomen and thorax to the left subclavian vein, where they are mixed with venous blood. Together with the blood contained in this great vein, the chyle and lymph are sent by a direct and short course to the lungs.

The result of the successive changes thus wrought upon the food by these progressive steps of the digestive process, is to approximate the crude aliment more and more nearly to the chemical condition of the blood. 'This is accomplished partly by the gastric and intestinal juices, and partly by matters combined with the food, highly animalized in their own nature, and endowed with assimilative properties, as the salivary secretion mixed with the food during mastication; the pancreatic and biliary secretions mixed with the food during the conversion of chyme into chyle; the mesenteric secretions mixed with the elaborated chyle of the mesenteric glands; and, lastly, organized particles, which have already formed a part of the living structures of the body, mixed with the chyle under the form of lymph in the thoracic duct.'

In the stomach, by the agency of the gastric juice, a superfluity of water is chemically combined with the original element of the nutritive matter contained in the food, by which the solution of the food is effected. This Dr. Prout terms a reducing process, because, by its combination with water, the nutritive element is reduced to a weaker state. This element Dr. Prout conceives to be albumen, although he states that he has been unable to detect true albumen in the stomach when none has been present in the food. 'Though the proportions,' he says, 'of the different ingredients of the chyle, as ultimately formed, are liable to be much varied, according to the nature of the food, yet whatever the nature of the food may be, the general components and character of the chyle remain always the same. The stomach must therefore be endowed with a power or faculty, the agency of which is to secure the uniform composition of the chyle by appropriate action upon such materials as circumstances may bring within its reach. For indeed the chief materials from which chyle is formed, namely, the albuminous and oleaginous principles, may be considered as already fitted for the purposes of the animal economy, without undergoing any essential change in their composition. But the saccharine class of aliments, which form a very large part of the food of all animals (except of those subsisting entirely on flesh), are by no means adapted for such speedy assimilation. Indeed, one or more essential changes must take place in saccharine aliments previously to their conversion either into the albuminous or into the oleaginous principles. Most probably, under ordinary circumstances, these essential changes are altogether chemical, that is to say, they are such as do take place, or rather would take place, if the elements of the substances thus changed in the stomach could, out of the body, be so collocated as to bring into action the oppositions necessary to produce these changes. Thus the saccharine principle spontaneously becomes alcohol, which is merely an oleaginous body of a weak kind. When therefore in the stomach it is requisite that sugar be converted into oil, it is probable that the sugar passes through precisely the same series of changes it undergoes out of the body, during its conversion into alcohol. We

cannot trace the conversion of sugar into albumen, because we are ignorant of the relative composition, and of the laws which regulate the changes of these two substances.'

If the indications of albumen in the chyme be not well marked, albumen is largely developed in the chyle of the small intestines, while, in that of the mesenteric glands and the thoracic duct, a large portion of the watery particles in the chyme of the stomach and the chyle of the intestines is removed, so that the action of the mesenteric glands seems to be the converse of that of the stomach, namely, a completing power by which the albumen is progressively brought nearer and nearer the condition in which it exists in the blood.

It is the office of the large intestines into which only a very small portion of chyle enters, to prepare the excrementary part of the aliment for its expulsion, and to generate the force by which, when duly prepared, it is conveyed from the body. These organs possess a modification of structure adapting them in the most admirable manner for the performance of this two-fold office. A concise description of the apparatus of digestion, and a more minute account than could be given here of its phenomena, will be found in the chapter on digestion in the 'Philosophy of Health,' and the details of all that is known upon the subject up to the present time are contained in Mayo's 'Physiology,' Bostock's 'Elements of Physiology,' Elliotson's 'Blumenbach,' and Tiedemann's 'Physiology of Man;' the first volume of which is translated by James Manby Gully, M.D., and J. Hunter Lane, M.D., F.L.S.

DIGESTION, in chemistry, and especially in pharmaceutical chemistry, is the exposure of any substance to partial or total solution in a fluid, either at common temperatures or with a gentle heat: thus in the preparation of tinctures, the substance whose virtue is to be extracted is said to be *digested* in alcohol or spirit of wine, generally diluted with water. It is commonly performed in a glass matrass, which should not be more than half filled, and covered with a piece of wet bladder, so that the evaporation of the menstruum or spirit may be prevented as much as possible; if the heat be so great as to endanger the bursting of the vessel or the bladder, the latter should be pierced with one or more small holes.

The matrass may be heated either by means of the sun's rays, of a common fire, or of the sand-bath, or a stove: when the heat is so great that it would occasion the loss of a valuable menstruum, as spirit of wine, without any provision for condensing it being employed, a distilling apparatus should be made use of. Formerly a method of digestion called *circulation* was resorted to; this consisted in luting a close head on the matrass, in which the vapour was condensed, and ran back out of the digester without loss, it being condensed in the head merely by exposure to the air.

DIGGES, LEONARD, a distinguished mathematician of the sixteenth century, was descended from an antient family in the county of Kent. He was born at Diggescourt, in the parish of Barham, in the same county. He was educated at Oxford; but having an ample property, he retired to his own seat, devoting his life to the study of geometry and its practical applications, which he cultivated with great success. He died in 1574. His writings abound with invention, and his views are developed with great perspicuity and clearness; but the subjects on which he wrote, and the improvements which he made being now familiar to all practical mathematicians, any account of them beyond the titles of the works which he wrote would be superfluous here

1. 'Tectonicum; briefly showing the exact Measuring and speedy Reckoning of all manner of Lands, Squares, Timber, Stones, Steeples, &c.' 4to., 1556. This was enlarged and improved in a second edition by his son Thomas Digges, in 1592; and this again was reprinted in 1647.

2. A geometrical and practical treatise, under the title of 'Pantometria;' in three books; which he left in MS., and which was printed with improvements by his son; fol., 1591.

To this was added by the editor, 'A Discourse Geometrical of the Five Regular and Platonic Bodies, containing sundry Theoretical and Practical Propositions arising from the mutual Conference of these Solids, Inscription, Circumscription, and Transformation.' Before this time geometers had but little extended the investigations contained in the 15th book of Euclid; and this curious treatise contained the most ample collection of properties that appeared

in any book before the time of the publication of Abraham Sharpe's 'Geometry Improved.'

3. 'Prognostication Everlasting of Right Good Effect; or, Choice Rules to judge of the Weather by the Sun, Moon, Stars, &c.' 4to., 1555, 1556, and 1564. Also with corrections and additions by his son; 4to., 1592.

DIGGES, THOMAS, the only son of Leonard Digges. He was educated by his father with great care, and afterwards at Oxford, where he much distinguished himself; and ultimately became one of the first mathematicians of his age.

He chose the military profession, and was appointed muster-master-general to the forces sent out by Queen Elizabeth to succour the oppressed inhabitants of the Netherlands. Of his military career, however, no other evidence is known to exist, except his writings on the subject. These prove that he must have given considerable attention to the details of his profession, and therefore have been a considerable period on active service. The following is a list of his published writings, independently of editing his father's works:—

1. *Alæ sive Scalæ Mathematicæ*, 4to., 1573. A curious work.

2. A Letter on Parallax, printed in Dee's *Parallacticæ Commentationis praxeosque nucleus quidam*, 4to., 1573.

3. An Arithmetical Military Treatise, containing so much of arithmetic as is necessary towards military discipline, 4to., 1579.

4. An Arithmetical Warlike Treatise, named *Stratoticos*, compendiously teaching the science of numbers as well in fractions as integers, and so much of the rules and equations algebraical, and art of numbers cossical, as are requisite for the profession of a souldier. Together with the moderne militaire discipline, offices, laws, and orders in every well-governed campe and armie, inviolably to be observed, 4to., 1590.

5. A brief and true Report of the proceedings of the Earle of Leicester, for the Relief of the town of Sluice, from his arrival at Vlishing, about the end of June, 1587, untill the surrender thereof, 26 Julii ensuing, whereby it shall plainly appear his excellencie was not in anie fault for the surrender of that towne. Published with the last, 1590.

6. A brief discourse what orders were best for repulsing any forraigne forces, if at anie time they should invade us by sea in Kent or elsewhere. Published with the two last, 1590.

7. A perfect description of the celestial orbs according to the most antient doctrine of the Pythagoreans. This was published as a supplement to his edition of his father's *Prognostication Everlasting*, 4to., 1592.

8. A humble motive for Association to maintain the Religion Established, 8vo., 1601.

To this is added a letter to the Archbishops and Bishops to enforce the same object.

9. England's Defence: or a treatise concerning invasion; written in 1599, but not published. It is, essentially, a second edition of the tract already spoken of in the *Stratoticos*.

Digges wrote many other works which he left in MS., and which have never been published, on account, it is stated, of the perplexity created by lawsuits in which he was engaged. He died in 1595; but, except the accomplished politician and elegant writer, Sir Dudley Digges, none of his children claim a niche in the history of their times, though two others were authors of printed works.

DIGIT, a finger, a term employed to signify any symbol of number from 0 to 9. According to the original application of the term, the ten first numbers should be called digits, but universal practice employs the word to signify the ten symbols used in reckoning numbers. Thus ten (10) is a number of two digits.

DIGITALIA, a vegetable alkali procured from the *Digitalis purpurea*, or foxglove: but little is known of this substance; it is stated to have been obtained in minute prisms with a rhombic base. Digitalia resembles the other vegetable alkalis in restoring the blue colour of litmus which has been reddened, and in the bitterness of its taste, but it is much more soluble in water than they generally are. It has not been analyzed. Its therapeutic action is stated to be similar to that of the foxglove.

DIGITALIS, a genus of Scrophulariaceous plants, distinguished by its five-parted leafy calyx, its irregular funnel-shaped inflated corolla with an oblique limb, the upper lip of which is short and two-lobed, the lower three-lobed, and its ovate acuminate capsule, splitting into two many-seeded valves. The flowers in all the species are arranged

in long racemes, are either yellow, purple or brown, and generally showy; the leaves alternate upon a round herbaceous stem.

Several species are known, the most complete account of which is in Lindley's 'Digitalium Monographia;' it is however probable that some of the so-called species in that work are mere varieties or hybrids. *D. lutea* is a common plant in the woods of France and Germany. *D. ochroleuca* and *grandiflora* are met with rather more to the eastward; while *D. ferruginea* and its allies, with short roundish rust-coloured flowers, occur not unfrequently in the south-eastern parts of Europe and in Asia.

Over all the west of Europe, but not in Asia, is found abundantly, especially in England and France, the *D. purpurea*, a very handsome species, with large purple or white flowers, to which the name of foxglove is popularly applied. It is a biennial, with oblong, stalked, scalloped, wrinkled leaves, grey with hairs, and a stem about two feet high, also covered with a close soft nap. The purple or white pendulous flowers are above an inch and a half long, and are arranged in one-sided racemes; in the inside of their corolla, on the lower lip, they are bearded with long hairs, and gaily spotted with blackish purple specks. There are four didynamous stamens shorter than the corolla, with large smooth anthers two-lobed at the base.

The energetic, stimulating, acrid, narcotic properties of this plant have caused it to be extensively employed medicinally.

DIGITALIS PURPUREA, fox-glove, a biennial plant, of which the leaves and seeds are used. The leaves are sometimes accidentally confounded with those of different species of verbasum, and of the conyza squarrosa. The most powerful leaves are those procured from plants growing on the sunny sides of hills. They must be carefully dried, and protected from damp. The active principle appears to reside in an extractive substance, which by careful evaporation may be crystalized, and to which the name of Digitaline has been given. This principle is soluble in water, in alcohol, and possibly in æther. It is very poisonous. One grain dissolved in a little water killed a rabbit in a very short time. Digitalis is given in powder, made into pills, or in an alcoholic tincture. Diversity of opinion exists respecting its primary action on the system, some writers considering it as primarily a stimulant, and the sedative effect a consequence of the previous excitement; others regarding it as a direct sedative. It is most likely that it acts in both ways according to the dose, and frequency of administration. If a small dose be given, and repeated at short intervals, a stimulant action will be most obvious, followed at a considerable interval by a sedative effect. If on the other hand a large dose be given at first, the sedative action is immediately displayed. The effect varies also with the position of the person, being different according as he is standing, sitting, or reclining.

Digitalis is the most perfect example known of a cumulative poison, as it may be used for some time, if the doses be small, without producing any manifest effect for several days, when suddenly faintness, intermittent pulse, giddiness, and other alarming symptoms appear. These are best combated by vital stimulants, such as warm brandy and water.

Digitalis has the power of reducing in a remarkable degree the heart's action, bringing down the pulse from 120 or more to 50 or 40 beats in a minute, and causing it to become at the same time intermittent. On this power depends its medical value in some diseases. It is remarkable however that while it thus lowers arterial action, it excites the absorbents and the kidneys to increased action, and so proves a valuable diuretic in dropsy and some other diseases. It is most useful in organic affections of the heart, and in the latter stages of some inflammatory affections, such as pneumonia, in phthisis pulmonalis, chronic peritonitis, and irritative or nervous fever. In the inflammatory or turgescient stage of hydrocephalus acutus, along with calomel, Golis states it to be very valuable.

As a diuretic, it is, like most medicines of that class, uncertain in its effects: it seldom answers if much inflammatory action exist when it is exhibited. To render it more certain it is generally given along with calomel, and squills, or some other diuretic.

DIGITIGRADES. [CARNIVORA, vol. v., p. 307.]

DIGNE. [ALPES, BASSES.]

DIGNITIES. [TITLES OF HONOUR.]

DIGY'NIA, a systematic name given by Linnæus in his artificial system, to such plants as have two styles, or a single style deeply cleft into two parts.

DIJON, in France, capital of the department of Côte d'Or, on the north-east bank of the river Ouche, a tributary of the Saône: 162 miles in a direct line south-east from Paris, and 183 miles by the road through Provins, Nogent sur Seine, Troyes, Bar sur Seine, and Châtillon sur Seine: in 47° 19' N. lat. and 5° 2' E. long.

Dijon existed, during the Roman dominion, under the name of Dibio or Divio. An antient legend, attested by Gregory of Tours, relates that the Emperor Aurelian made of Dibio a considerable fortress: other legends seem to confound Aurelian with Marcus Aurelius, who lived a century before. From the dominion of the Romans Dijon passed, in the fifth century, under that of the Burgundians [BURGUNDIANS], and subsequently of the Franks. Under the Carolingian princes, Dijon was a lordship of the bishops of Langres, who often resided here; and in the ninth century was under counts of its own, who held it of the bishops as suzerains. In the eleventh century the lordship of Dijon was united to the duchy of Bourgogne. [BOURGOGNE.] In the twelfth century the dukes caused the city to be rebuilt after it had been burned down, and subsequently bestowed upon it a municipal constitution. In the fourteenth century new walls were erected, inclosing the Roman town and the greater part of the suburbs. Under the dukes of Bourgogne, of the first race, Dijon was erected into a viscounty, but this came to an end A.D. 1276: and the rights of the viscounts were subsequently bestowed on the municipality and citizens. The dukes of Bourgogne, both of the first and second races, usually resided here: and when Louis XI. of France took possession of Bourgogne, and established the *parlement*, or provincial tribunal, he fixed its sittings in this town.

The town is situated in a plain bounded on the west by the hills which connect the Cevennes and the mountains of Forez with the heights of Langres and the Vosges. The Suzon flows south-east and southward through this plain, and joins the Ouche under the walls of Dijon; at Val de Suzon, a few miles from Dijon, it is a tolerably copious stream, while at Dijon it is frequently dry. The streets of Dijon are not regularly laid out, but they are clean and cheerful. The houses, which are of freestone, are only of one or two stories. Of the public buildings the office of the prefect and the former palace or hall of the states of Bourgogne are the most worthy of notice: the latter contains a museum of painting and sculpture, antiquities, and subjects of natural history, and a library of 40,000 volumes; behind it is an old tower used as an observatory. In front of the palace of the states is the 'Place Royale,' an open space, surrounded by houses. There are no fountains in Dijon. The church of St. Benigne, the present cathedral, is a gothic edifice, the spire of which is admirable for its height (nearly 300 feet) and the lightness of its architecture; the interior of the church contains some fine marble tombs. The church of Notre Dame, the former cathedral, is also in the gothic style. The church of 'Les Orphelins-Sainte Anne' is an elegant modern structure, surmounted by a fine dome. The Chartreuse, or Carthusian monastery, which was outside the walls of the city on the road to Semur, and was adorned by the sumptuous tombs of the dukes of Bourgogne, has been demolished: some remains of these tombs have been preserved in the museum. There is a theatre, erected within a few years. An antient castle, flanked with immense towers, is said to have existed during the kingdom of the Burgundians, and it may be of yet higher antiquity, if we may identify it with the Roman walls which Expilly describes as remaining in his time (A.D. 1763). The ramparts of the town are kept up, and are planted nearly all round with fine trees. There are walks planted with trees round the town in its present extent, including the suburbs, which form a second circuit of promenades: and there are other promenades, in one of which (l'Arquebuse) is an immense poplar, 25 or 26 feet in circumference. (Vaysse de Villiers.) There are baths and a mineral spring.

The population of Dijon amounted in 1832 to 25,352 for the town, or 25,552 for the whole commune: this number very nearly coincides with the estimated population given by Expilly in 1763. The manufactures of Dijon include hosiery, blankets, coloured woollen-yarn, cotton-yarn, cotton-velvets, printed calicoes, muslins, linen, leather, hats, vinegar, mustard, which last is in high repute with epicures, and

starch; there are many breweries. Considerable trade is carried on in corn, wine, wool, and wax candles. There is a nursery for mulberry trees. Dijon is well situated for trade at the junction of several roads; the canal de Bourgogne, which unites the Yonne with the Saône, and thus opens a communication between the basin of the Seine and that of the Rhône, passes along the valley of the Ouche, close to the town.

Dijon has long been eminent for the cultivation of science and literature. It is the seat of an académie universitaire, comprehending faculties of law, sciences, and literature. There are also a collège or high school, a seminary for the priesthood, a school of the fine arts, a school of drawing, and a secondary school of medicine: courses of instruction are delivered on geometry and mechanics applied to the arts, and on botany. There are academies of sciences, belles lettres, and arts; and a society of jurisprudence; also a botanic garden. Dijon has produced a number of eminent men, as Bossuet, Larcher, Guyton-Morveau, Daubenton, Crebillon, and Piron. Two of the dukes of Bourgogne, Jean-sans-Peur and Philippe le Bon, were born here.

The bishopric of Dijon was established in 1731: the diocese was dismembered from that of Langres, with the addition of a few parishes from the diocese of Autun. At present it comprehends the department of Côte d'Or. The bishop is a suffragan of the archbishop of Lyon and Vienne.

Dijon is the seat of a 'Cour Royale,' the jurisdiction of which comprehends the departments of Côte d'Or, Haute Marne, and Saône and Loire, which have an aggregate population of 1,149,674: there is also a 'Tribunal de Commerce.' It is the head-quarters of the eighteenth military division, which comprehends the departments of Aube, Côte d'Or, Haute Marne, Saône and Loire, and Yonne. The arrondissement of Dijon had, in 1832, a population of 135,435.

DILAPIDATIONS. In its legal sense, this term is confined to the pulling down or destroying, in any manner, any of the houses or buildings belonging to an ecclesiastical benefice, or suffering them to run into ruin or decay, or wasting or destroying the woods of the church, or suffering any wilful waste in or upon the inheritance of the church. An incumbent is bound to keep the buildings in repair, restoring and rebuilding where necessary according to the original form, without addition or modern improvement, but he is not bound to supply or maintain anything in the nature of ornament, such as painting (unless necessary to preserve exposed timbers from decay), whitewashing, and papering. For damages calculated on this principle the successor may bring his action, either in the courts of common law or in the spiritual court, against his predecessor, or, if he be dead, against his executors.

The right to damages for dilapidations, as between other persons, is governed either by the laws relating to waste and repairs, or by special contract.

DILATATION. [EXPANSION.]

DILL, an aromatic umbelliferous plant, whose fruit is employed medicinally as a useful carminative. It is a Spanish biennial, and is called *Anethum graveolens* by botanists.

DILL. [CARMINATIVES.]

DILLENIA'CEÆ, a natural order of plants, belonging to Polypetalous Albuminous Exogens, and related on the one hand to Magnoliaceæ, on the other to Anonaceæ. They are briefly characterized by having five sepals in a broken whorl; five petals; an indefinite number of stamens; a definite number of ovaries, which are either quite distinct or more or less consolidated; berried, or capsular and two-valved fruits; seeds surrounded by a pulpy aril; and, finally, a minute embryo lying in solid fleshy albumen. Differentially considered, Dilleniaceæ plants are distinguished from Anonaceæ by their flowers being arranged upon a quinary, not ternary, type, by their albumen being solid, and not ruminated, and by their want of aromatic properties; from Magnoliaceæ by their want of stipules, and the presence of a pulpy aril round the seeds.

The plants of this order are chiefly Asiatic trees or shrubs, and usually yellow-flowered. A few occur in America. The trees are found in the woods of Tropical India; the bushes inhabit New Holland, especially in the more temperate parts, and in China; the woods of Brazil contain several kinds, usually climbers or having a trailing

habit. They appear to possess astringent properties, but nothing further of importance.

The species in cultivation in this country are almost all Australasian, and have something the appearance of yellow-flowered Cistuses. Among these occur species of the curious genus *Pleurandra*, in which the stamens are developed on one side only of the flower, all those on the opposite side being abortive. There are few analogies to this in the vegetable kingdom. *Hibbertia volubilis* is a showy twiner, but its flowers are intolerably offensive in their smell.

1, A flowering shoot of *Hibbertia volubilis*; 2, the calyx and carpels, with one stamen only remaining; the other stamens cut away to show the carpels in the centre of the flower; 3, the ripe fruit.

DILLON. [ROSCOMMON, LORD.]

DILUENTS comprise those liquids which are used to dilute the fluids of the human body, and thereby modify their nature. They are employed when the secretions are too viscid, or the contents of the stomach, of the intestines, or any of the glands are too acrid, and also when the heat of the body, as indicated by thirst, &c., is too great, and causes a feeling of uneasiness. They manifest their beneficial effects most quickly when the contents of the stomach or upper part of the intestines require to be diluted, as in the case of many poisons; but they also reach the kidneys or skin in a very short time after their introduction into the system, and render less acrimonious the secretions of these organs. Their utility in allaying the thirst of patients affected with fevers and other inflammatory complaints is well known, and from such patients they ought never to be withheld, as they were at one time when erroneous notions on the subject prevailed, as they not only mitigate the sufferings of the invalid, but often determine to the skin, and cause a critical perspiration. It is equally cruel and injurious to withhold drinks of a mild kind from dropsical subjects, though they require to be used by such persons in greater moderation.

Water is the simplest and often the best diluent, but it may be rendered more agreeable in some cases by being made into toast-water, or by having acids or other substances added to it. Whey or butter-milk are also agreeable diluents in many cases. The excessive use of fluids at meal-times seems to be hurtful to digestion; and diluents appear to be less proper for persons of a soft and lymphatic constitution than for the robust and sanguine. Children of a scrophulous constitution do not prosper so well on a fluid as on a dry diet; they should therefore be allowed liquids in a very moderate degree, especially towards evening.

DIMENSION (algebra), a term which is used in the same sense as DEGREE. Thus x^2y is of three dimensions or of the third degree. In geometry, length is of one dimension, surface of two, and solidity of three. Thus geometry of three dimensions means solid geometry.

DIMYARIA. [CONCHIFERA, vol. viii., p. 431.]

DINAGEPORE, a district of Bengal, lying between 25°

and 27° N. lat., and between 88° and 89° E. long., bounded on the north by Rungpore and Purneah, on the east by Rungpore and Mymunsingh, on the south by Mymunsingh and Rajshahy, and on the west by Purneah and Boglipore. The form of the district is triangular, the base being to the south; its greatest length from south to north is 105 miles, and its extreme breadth from east to west is 82 miles. A survey was made of the district in 1808 by Dr. Francis Buchanan, and its area was then found to comprise 5374 square miles, made up as follows:—

Rivers, tanks, water-courses, and marshes	353
Lands inundated during the rainy seasons	381
Red Clay	38
Light coloured clay	2441
Free soil	2161
	5374

The principal rivers by which the district is intersected are the Teesta, the Mahananda, and the Korotoya. During the rainy season, which usually sets in about the middle of June, and lasts for four months, these and many smaller tributary streams admit the passage of boats to almost every village in the district.

The surface of the country is undulating, but the greatest inequality of surface does not exceed 100 feet. The soil is generally light, and the principal cultivation being rice, the success of the harvest depends mainly upon the quantity of rain. Hemp, sugar, indigo, and a small quantity of cotton, are also cultivated, the first in order to prepare from its buds and leaves an intoxicating drug: several other fibrous plants are cultivated for the purpose of making cordage. The horses and oxen bred in Dinagepore are of very poor degenerate kinds; the former, which are not larger than ponies, may be bought at various prices from 2 to 6 rupees (4s. to 12s.) each. Tigers, bears, wild-buffaloes, and wild-hogs are very troublesome to the cultivators of land; the buffaloes and hogs run about in large herds, and commit great havoc in the fields. Otters are also very numerous, as well as the common porcupine. Wild water-fowl of various kinds are also seen in large flocks; the common wild-goose is most abundant, and is considered good eating. The natives also eat some kinds of lizards; but the chief part of the animal food consumed in this district consists of fish, which is so abundant that during the periodical inundation of the rice fields great numbers of small fishes are taken in them, and on the subsidence of the water many are left behind in the mud, and are taken without any trouble.

The principal towns are Dinagepore, the capital; Malda; Gour; and Raygunge; besides which the district contains a great number of villages. The whole population of Dinagepore was estimated by Dr. Buchanan in 1808 at 3,000,000: since that time it is believed that the numbers have somewhat increased. About seven-tenths of the inhabitants are Mohammedans, and the remaining three-tenths Hindus.

The district was formerly much infested by Dacoits or gang-robbers, but owing to the vigorous measures adopted by the English government in 1814 the evil was greatly checked, and has since entirely ceased.

Dinagepore, the capital of the district, is situated in 25° 37' N. lat., and 88° 43' E. long., about 100 miles N.N.E. from Morshedabad. The houses, computed at about 5000 in number, are mostly of a mean description, little better than huts; a few dwellings of European residents are large and commodious, but without any architectural beauty. The population of the town is computed at 30,000. (Buchanan's *Statistical Survey; Report of Committees of House of Commons*, 1832.)

DINAN, a town in France, in the department of Côte du Nord, on the slope of a hill on the left bank of the river Rance, a few miles above the mouth, 199 miles west, or west by south, from Paris in a strait line, or 220 miles by the road through Dreux, Alençon, Mayenne, Fougères, and Dol; in 48° 27' N. lat., and 2° 4' W. long. Dinan was in the middle ages the occasional residence of the dukes of Bretagne, who had here a castle, which still remains: ancient ramparts of the town are standing, and are of vast height and thickness. The church contains the heart of the Constable du Guesclin. There are extensive and pleasant public walks and a concert-room. In a valley, a short distance north of the town, are the chalybeate waters of

Dinan, which are in considerable repute for affections of the liver.

The population of Dinan, in 1832, was 8044: the inhabitants are engaged in an extensive trade in cider, beer, hemp, flax, honey, wax, butter, tallow, skins, cattle, and horses. There are salt-works, and manufactures of linen yarn, linen, cotton, flannel, shoes, and hats. The river is navigable, at high water, for boats of a considerable size up to Dinan; and the canal of the Ille and the Rance joins the river just above the town, opening a water communication with Rennes and the interior of Bretagne. The country round is fertile in corn and flax.

This town is the capital of an arrondissement which contained, in 1832, a population of 111,739.

DINANT, a very old town in the province of Namur, about 12 miles south of the city of Namur, in 50° 15' N. lat., and 4° 54' E. long. It is situated on the right bank of the Maas on a narrow strip between that river and a high rock. Part of it is on some islands in the Maas. The summit of this rock is defended by a strong fort. The population amounted in 1830 to 4337. The town contains several salt-refineries, four mills for sawing marble, some quarries of which are worked in the neighbourhood, several grist mills, paper-mills, breweries, and tanneries. Dinant formerly contained many extensive coppersmiths' works, but this branch of industry has almost entirely disappeared. A considerable quantity of gingerbread is made in the town and sent to different parts of the kingdom.

Dinant is conjectured to have taken its name from a temple dedicated to Diana, which once stood on the spot. In 559 it was enumerated among the possessions of the Bishoprick of Liege. In 870 it came into the possession of Charles the Bald. In the 12th century the town was fortified and considered a place of great strength. In 1466 Dinant was taken by the army under Philip the Good, and given up to pillage during three days. On this occasion 800 of the inhabitants were tied back to back and thrown into the Maas, and their houses were burnt. In 1554 the town was taken and pillaged by the French, and again in 1575 after a siege of eight days. At the treaty of Ryswick it was restored to the Bishop of Liege, but was again taken by the French in the war of the revolution, and constituted the chief place of an *arrondissement* in the department of the Sambre and Meuse. It was occupied by the allies in 1813. Dinant is on the high road between Namur and Givet. (Van der Maelen's *Dictionnaire Géographique de la province de Namur*.)

DINARCHUS, (Δειναρχος), one of the ten Greek orators, for the explanation of whose orations Harpocration compiled his lexicon. Dinarchus was a Corinthian by birth, who settled in Athens and became intimate with Theophrastus and Demetrius the Phalerian, a circumstance which combined with others enables us to determine his age with tolerable precision. Dionysius of Halicarnassus fixes his birth about the archonship of Nicophemus, B.C. 361. The time of his highest reputation was after the death of Alexander, when Demosthenes and other great orators were dead or banished. He seems to have got his living by writing speeches for those who were in want of them, and he carried on apparently a profitable business this way. After the garrison which Cassander had placed in Munychia had been driven out by Antigonus and Demetrius [ATHENS, p. 18] in the archonship of Anaxicrates, B.C. 307, Dinarchus, though a foreigner, being involved in a charge of conspiring against the democracy, and having always been attached to the aristocratical party, and perhaps also fearing that his wealth might be a temptation to his enemies, withdrew to Chalcis in Eubœa. Demetrius afterwards allowed him to return to Athens with other exiles, in the archonship of Philippus, B.C. 292, after an absence of fifteen years. On his return Dinarchus, who had brought all his money back with him, lodged with one Proxenus, an Athenian, a friend of his, who, however, if the story is true, proved to be a knave and robbed the old man of his money, or at least colluded with the thieves. Dinarchus brought an action against him, and for the first time in his life made his appearance in a court of justice. The charge against Proxenus, which is drawn up with a kind of legal formality, is preserved by Dionysius of Halicarnassus. Of the numerous orations of Dinarchus only three remain, and they are not intitled to very high praise. One of them is against Demosthenes touching the affair of Harpalus. [DEMOSTHENES.] Dionysius has taken great pains to distinguish

the spurious from the genuine orations of Dinarchus. Of his genuine orations he enumerates 28 public orations and 31 private. This critic has passed rather a severe judgment on Dinarchus. He considered him merely as an imitator of Lysias, Hyperides, and Demosthenes, and though succeeding to a certain extent in copying the several styles and excellencies of these three great orators, yet failing, as all copiers from models must fail, in that natural expression and charm which are the characteristics of originality.

The few facts that we know about Dinarchus are derived from the Commentary of Dionysius on the Attic orators and the extracts which he gives from Philochorus. The three extant orations of Dinarchus are printed in the usual collections of the Attic orators.

DINDIGUL, a district in the Carnatic, bounded on the north by Coimbatore and Trichinopoly, on the east by the Bay of Bengal; on the south by Travancore and Tinnevely, and on the west by Travancore and Coimbatore. The district is for the most part mountainous and woody, and the general surface of the country is 400 feet above the level of the sea. The Dindigul valley, inclosed by the Pilny mountains on the north, by the Travancore mountains in the west, by a range of hills on the east which extend from the town of Dindigul in the north to Sheragurry in the south, and on the south by the western ghauts, is a level tract of country 75 miles long from north to south, by about 20 miles broad. The district is watered by the Vyaar or Vaygaroo river, which rising at the base of the Alligherri hills south of the town of Dindigul, passes close to Madura, traverses the zemindaries of Shevagunga and Ramnad, and is almost wholly absorbed in a large tank about 20 miles south of Tondi, a considerable part of its waters having been previously diverted for the purposes of irrigation: except when the floods are more than usually great the bed of the river is altogether dry below Ramnad. The climate of Dindigul is reckoned much superior to that of most other parts of the south of India, the heat being much tempered by the showers caused by the interception of the clouds by the mountains, while in the cold season the thermometer seldom or never falls below 65°. The district was ceded to the English by Tippoo in 1792, and together with Madura, the Manapara pollams, Ramnad and Shevagunga has since been formed into a collectorate under the Madras presidency. The population of this collectorate was ascertained in 1822 to amount to 601,293 persons. The population of Dindigul alone has not been stated for a later period than 1811 when it amounted to 295,654 persons. Dindigul the capital of the district is situated in 10° 18' N. lat., and 75° 2' E. long.: 198 miles from Seringapatam and 275 miles from Madras, travelling distances. The town is clean and neat and contains about 7000 inhabitants.

DINEMOURA. [PÆCILOPODA.]

DINETUS, a genus of Hymenopterous insects, of the section Fossores. [LARRIDÆ.]

DINGLE, a corporate town on a bay of the same name, in the barony of Corcaguinny and county of Kerry, in Ireland; distant from Dublin 164 Irish or 208 English miles. The limits of the corporation embrace a circuit of two Irish miles by land and sea, measured from the parish church.

The antient name was Dangan-I-Cushy, or the fortress of Hussey, an adventurer of English descent, to whom one of the family of Desmond granted the tract of country on which the town stands. The name has been corrupted to Dangan-I-Couch and Dingle-I-Couch, in which latter form it is still commonly used. During the latter end of the sixteenth and beginning of the seventeenth century, Dingle enjoyed a considerable traffic with Spain, from which large quantities of wines and spices were annually imported here in return for its exports of fanned hides, Irish friezes, woollen stockings, salt beef, butter, and salmon. The town was erected into a corporation by Queen Elizabeth in 1585, at which time it sent members to the Irish parliament. About the same time it was walled in; but the walls being built of clay mortar, from the difficulty of procuring lime, soon fell to decay. It is now governed by charter of the 4th of James I. The corporation consists of sovereign, twelve burgesses, and an unlimited number of freemen. There are held a Tholsel court, court of conscience, and petty sessions once a fortnight; but the quarter-sessions which were formerly held here have been removed to Tralee, a distance of 27 miles, which is said to be productive of some inconvenience.

The town has an antique appearance. Some of the old

houses are in the Spanish taste, with stone balconies, &c., and several bear date as early as the reign of Elizabeth. The vaults of the old castle built by Hussey were standing in 1780, and used as the town-gaol. The parish church, dedicated to St. James, is said to have been built at the charge of the Spanish who frequented the port; it was a large structure, but is now much decayed. The residence of the proprietor, the knight of Kerry, is the principal modern building, attached to which are some well laid out gardens. A new bridewell has lately been built here. There are also a market-house and small barrack.

The town is not lighted or watched; the streets, roads, and bridges are repaired by county presentments, and the duties of a police are performed by a portion of the constabulary force of the county.

The harbour, a land-locked creek on the northern side of the great æstuary called Dingle Bay, is capable of floating vessels of 300 tons up to the town, and is pretty well protected from the westerly winds which prevail on this coast. From the difficulty however of distinguishing the entrance, vessels bound for Dingle in a westerly gale run a risk of going to leeward on the dangerous shoals of Castlemain harbour at the head of the estuary. In 1765 a sum of 1000*l.* was voted by the Irish parliament in aid of the building of the quay. The town has improved very much within the last twenty years, although the linen trade, which formerly flourished here, has declined. The chief trade is an export of butter and corn to Liverpool. The foreign trade is confined to a single vessel. Average coasting tonnage for Great Britain, inwards, 550 tons; outwards, 500 do.; for Ireland, inwards, 200 tons; outwards, 100 do.

Population in 1821, 4538; do. in 1831, 4327: decrease in 10 years, 211. Total population within the limits of the borough in 1831, 9329. In the parish of Dingle there were, in 1834, 5 schools, educating 284 males and 106 females; of these two were small free schools. (Smith's *History of the County of Kerry; Reports of the Commissioners on Municipal Corporations, Ireland, &c.*)

DINGWALL. [ROSS, SHIRE OF.]

DINOPS. [CHEIROPTERA, vol. vii., p. 26.]

DINOTHERIUM, a genus of gigantic extinct herbivorous mammals established by Professor Kaup. The remains have been found most abundantly at Epplesheim in Hesse Darmstadt, in strata of sand referrible to the second period of the tertiary formations (Miocene of Lyell). Fragments are noticed as occurring also in several parts of France, Bavaria, and Austria, by Cuvier, who, from the resemblance of their molar teeth to those of the tapirs, at first considered the animals to have been an enormous species of the last-named genus.

We select as an example *Dinotherium giganteum*, the largest species yet discovered, and which is calculated both by Cuvier and Kaup to have attained the length of eighteen feet. The bones of the head and the teeth are the principal remains hitherto found. A scapula in form resembling more nearly that of a mole than any other animal, is the principal bone of the body yet found, and this shoulder blade has been considered as indicating a peculiar adaptation of the fore-leg to the purposes of digging. In the autumn of 1836, an entire head of the animal was disinterred at Epplesheim, measuring about four feet in length and three in breadth, of which Professor Kaup and Dr. Klipstein have given figures and a description*.

It will be seen from the cuts (which are copied from the works of Dr. Kaup and those of Drs. Kaup and Klipstein), as well as from the casts in the British Museum, that though the form of the molar teeth approximates to that of the tapirs, the tusks placed at the anterior extremity of the lower jaw and curved downwards somewhat after the fashion of those in the upper jaw of the Walrus, exhibit a remarkable deviation from this part of the dental formula in any other known animal, whether living or fossil. With this is combined a form of the lower jaw itself, which can not but arrest the attention of every observer.

Dr. Buckland, in the first edition of his *Bridgewater Treatise*, published before the appearance of the memoir of Dr. Kaup and Dr. Klipstein, giving figures and a description of the entire head, but after the publication of Dr. Kaup's earlier publication,—when adverting to the mammalia of the miocene period of Lyell, observes, that the

* Beschreibung und Abbildungen von dem in Rheinhausen aufgefundenen colossalen schädel des Dinotherii gigantei mit geognostischen Mittheilungen über die knochenführenden Bildungen des mittelhessischen Tertiärbeckens von Dr. J. J. Kaup, & Dr. A. v. Klipstein. 4to., Darmstadt, 1836.

Profile of the skull of *Dinotherium giganteum*. The dotted line shows the edge of the coronoid process of left lower jaw, through the ramus of which the last molar tooth and a portion of the last but one are supposed to be seen. The zygomatic arch is fractured and the intermediate portion of it lost.

Profile of lower jaw of *Dinotherium giganteum* (another individual) with the coronoid process gone, and only two teeth in sight. The length of this, including the task, is nearly four feet.

Skull of *Dinotherium giganteum* seen from above.

Skull of the same seen from below.

Portions of the skull of the same; *a*, posterior part of the skull seen from below, showing the occipital condyle and foramen, &c. &c.; *b*, roof of the mouth and molar teeth; the interval between the rows widening from before backwards.

second, or miocene system of tertiary deposits, contains an admixture of the extinct genera of lacustrine mammalia, of the first or eocene series, with the earliest forms of genera which exist at the present time. This admixture, he adds, was first noticed by M. Desnoyers, in the marine formations of the Faluns of Touraine, where the remains of *Palæotherium*, *Anthracotherium*, and *Lophiodon*, which were the prevailing genera in the eocene period, are found mixed with bones of the *Tapir*, *Mastodon*, *Rhinoceros*, *Hippopotamus*, and *Horse*. These bones are fractured and rolled, and sometimes covered with *flustra*, thus giving indication of having been derived from carcasses drifted into an estuary or sea. Similar admixtures, continues Dr. Buckland, have been found in Bavaria and near Darmstadt, and many of these animals also indicate a lacustrine, or swampy condition of the regions they inhabited. One of them (*Dinotherium giganteum*) is stated to have attained eighteen feet in length and to have been the largest of all terrestrial mammalia yet discovered, exceeding even the largest fossil elephant.

In this view of the subject, it becomes of importance to see what were the remains which were found in the strata of sand at Epplesheim near Alzey, about twelve leagues south of Mayence, in company with those of the *Dinotherium*

Dr. Kaup in his 'Description d'ossements fossiles' (Darmstadt, 1832), gives the following number of species:—*Dinotherium* 2; *Tapirus* 2; larger than living species. *Chalicotherium* (allied to *Tapirs*) 2; *Rhinoceros* 2; *Tetracaulodon* (allied to *Mastodon*) 1; *Hippotherium* (allied to *Horse*) 1; *Sus* 3; *Felis* (some as large as a *Lion*) 4; *Machairodus* (allied to *Bear*, *Ursus cultridens*); *Gulo* (*Glutton*) 1; *Agnotherium* (allied to *Dog*, but as large as a *Lion*) 1.

Dr. Buckland in the work and in the edition above quoted, after giving a description of the tusks of the *Dinotherium*, thus proceeds, 'I shall confine my present remarks to this peculiarity in the position of the tusks, and endeavour to show how far these organs illustrate the habits of the extinct animals in which they are found. It is mechanically impossible that a lower jaw, nearly four feet long, loaded with such heavy tusks at its extremity, could have been otherwise than cumbrous and inconvenient to a quadruped living on dry land. No such disadvantage would have attended this structure in a large animal destined to live in water; and the aquatic habits of the family of *Tapirs*, to which the *Dinotherium* was most nearly allied, render it probable that, like them, it was an inhabitant of fresh-water lakes and rivers. To an animal of such habits, the weight of the tusks sustained in water would have been no source of inconvenience; and, if we suppose them to be employed as instruments for raking and grubbing up by the roots large aquatic vegetables from the bottom, they would, under such service, combine the mechanical powers of the pick-axe with those of the horse-harrow of modern husbandry. The weight of the head, placed above these downward tusks, would add to their efficiency for the service here supposed, as the power of the harrow is increased by loading it with weights. The tusks of the *Dinotherium* may also have been applied with mechanical advantage to hook on the head of the animal to the bank, with the nostrils sustained above the water, so as to breathe securely during sleep, whilst the body remained floating at perfect ease beneath the surface: the animal might thus repose, moored to the margin of a lake or river, without the slightest muscular exertion, the weight of the head and body tending to fix and keep the tusks fast anchored in the substance of the bank; as the weight of the body of a sleeping bird keeps the claws clasped firmly around its perch. These tusks might have been further used, like those in the upper jaw of the *Walrus*, to assist in dragging the body out of the water; and also as formidable instruments of defence. The structure of the scapula already noticed seems to show that the fore leg was adapted to co-operate with the tusks and teeth, in digging and separating large vegetables from the bottom. The great length attributed to the body would have been no way inconvenient to an animal living in the water, but attended with much mechanical disadvantage to so weighty a quadruped upon land. In all these characters of a gigantic, herbivorous, aquatic quadruped, we recognize adaptations to the lacustrine condition of the earth, during that portion of the tertiary periods to which the existence of these seemingly anomalous creatures appears to have been limited.'

In his description of the figures of the remains of *Dinotherium* in the same work, Dr. Buckland observes that they were found in a sand-pit containing marine shells at Epplesheim, near Alzey, about forty miles north-west of Darmstadt, where they are preserved in the museum. He adds, that bones of *Dinotherium* have lately been found in tertiary fresh water limestone, near Orthes, at the foot of the Pyrenees; and with them remains of a new genus allied to *rhinoceros*; of several unknown species of deer; and of a dog or wolf, the size of a lion. The following conclusion terminates the note appended to the description in Dr. Buckland's first edition: 'From the near approximation of this animal to the living tapir, we may infer that it was furnished with a proboscis, by means of which it conveyed to its mouth the vegetables it raked from the bottom of lakes and rivers by its tusks and claws. The bifid ungual bone (Kaup, Add., table 11), discovered with the other remains of *Dinotherium*, having the remarkable bifurcation which is found in no living quadrupeds, except the *Pangolins*, seems to have borne a claw, like that of these animals, possessing peculiar advantages for the purpose of scraping and digging; and indicating functions concurrent with those of the tusks and scapulæ.'

Upon referring to the view of the skull of *Dinotherium giganteum* seen from above, the width of the anterior por-

tion of the cranium and the deep depression there visible will strike the observer as very remarkable; and we find that Professor Kaup has, in his restoration of the animal, furnished it with a considerable proboscis, and given its general form as a good deal resembling that of the tapir.

[Restoration of *Dinotherium giganteum*.]

Dr. Buckland, in the supplementary notes to his second edition, has the following notice, with a reference to p. 135. 'The *Dinotherium* has been spoken of as the largest of terrestrial mammalia, and as presenting in its lower jaw and tusks a disposition of an extraordinary kind, adapted to the peculiar habits of a gigantic herbivorous aquatic quadruped.' The Dr. then alludes to the entire head found in 1836, and thus proceeds:—'Professor Kaup and Dr. Klipstein have recently published a description and figures of this head, in which they state that the very remarkable form and dispositions of the hinder part of the skull show it to have been connected with muscles of extraordinary power, to give that kind of movement to the head which would admit of the peculiar action of the tusks in digging into and tearing up the earth. They further observe that my conjectures (p. 138) respecting the aquatic habits of this animal are confirmed by approximations in the form of the occipital bone to the occiput of *Cetacea*; the *Dinotherium*, in this structure, affording a new and important link between the *Cetacea* and the *Pachydermata*.' Dr. Buckland, in this second edition, gives a copy of the profile of the entire head and of the restoration.

This head has been exhibited at Paris, and seems to have excited great interest among the French zoologists; for we find in the 'Journal des Débats' of the 21st of March in the present year (1837) that at the sitting of the Académie Royale des Sciences de Paris on the day before, M. de Blainville read a note detailing his particular views of the position which the animal held in the animal series—views which, it is there stated, were adopted both by M. Duméril and M. Isidore Geoffroy Saint-Hilaire. These views are detailed in 'L'Institut' of the 22nd of March; and the subject is so interesting, that we here present them to the reader, more especially as they are so much at variance with the restoration, a copy of which is above given.

'M. de Blainville read a note on the fossil head of the *Dinotherium giganteum*, recently exhibited at Paris by MM. Kaup and Klipstein. According to M. de Blainville, the *Dinotherium* constituted a genus of mammifers of the family of the *Dugongs* and *Lamantins*, which family makes a part of the order or of the degree of organization named by the last-mentioned zoologist *Gravigrades*, on account of their heavy progression, and of which the first family is formed by the *Elephants*. The following were the grounds stated for this opinion.

'As regards the teeth, the molars, five in number on each side of each jaw, have their crown squared and deeply traversed by two transverse elevations, the same as in the *Lamantins*. But as this character occurs also in the *Tapirs* and *Kangaroos*, and even in the *Lophiodons*, it would be far from sufficient for deciding the question, if it were not joined with the absence of false molars and canines (a formula which produces a considerable space between the first molar and the incisors), and with the number and form of

these last, which entirely resemble small tusks; only they are implanted at the extremity of the lower jaw, and are directed downwards. Whether or no there existed a pair of incisors in the upper jaw, is an uncertain point, the two extremities of this jaw, which have been found, being more or less truncated. It may, however, be inferred, from the enlarged and thick form of a fragment found some years ago, that it is possible that the animal might have had upper incisors, but smaller than those below: perhaps only rudimentary.

As to the form of the head and its parts, it corroborates what the dental system had established. In fact, the occipital condyles are entirely terminal, or in the direction of the longitudinal axis of the head, as in the lamantins and the cetaceous edentata, modified for existence in the water. The occipital surface is large, subvertical, and even inclined from before, backwards, with a profound mesial depression, for the insertion either of a very strong cervical ligament or powerful muscles for the elevation of the head, and the basilar part of the skull is narrow in its component parts, while the syncipitofrontal region is, on the contrary, very flat, very wide, as in the lamantins and dugongs, overplumbing the temporal fossa, which is extremely wide and extremely deep, indicating enormous levator muscles for the lower jaw, not only for the purpose of mastication, but adapted besides for the particular action of that jaw, with its rake-like incisor teeth. This disposition of the temporal fossa is perfectly in harmony with the zygomatic arch, which is wide, thick, robust, and complete, as far as may be inferred from the portion which is broken, but which nevertheless offers the articulating surface of the corresponding bone, exactly as in the lamantins: perhaps, however, without the great enlargement which may be remarked at the jugal apophysis of the temporal bone in the latter. The orbit is, as in the animals last named, very small and lateral, but very largely open in the zygomatic fossa. The auditory aperture is small, narrow, and rather oblique from below upwards. The face is wide and flattened, prolonged and enlarged a little, as in the *Cetacea*, anteriorly. It presents in its middle a very large aperture, the composition of which it has not been possible to study on account of the position of the head, which is upside-down, but which aperture, though evidently wider and greater than that of the dugong, has evidently the greatest analogy to what exists in that animal. The posterior orifice of the nasal cavity is, on the contrary, very narrow. The sub-orbital hole is very considerable, but even less, perhaps, than it is in the dugong. With regard to the lower jaw, that again exhibits the greatest analogy to that of the dugong, from the manner in which its branches are curved downwards towards the anterior third part of their length; only, that of the *dinotherium* being armed at its recurved extremity with a tusk, the ascending ramus offers, in its width and its condyle, which is as transverse as in the *carnivora*, a concordant disposition; so that the only motions permitted should be those of elevation and depression, as in those animals. The ethmoid surface of the temporal bone, also, is, as it were, a portion of a hollow transverse cylinder, with an apophysary lamina, having an extremely strong ridge—"une lame apophysaire d'arrêt extrêmement forte." "With this element (says M. de Blainville) we may regard it as nearly beyond doubt that the *Dinotherium* was an animal of the family of the *Lamantins*, or *Aquatic Gravigrades*, its proper position being at the head of the family, preceding the *Dugong*, and consequently preceded by the *Tetracaulodon*, which ought to terminate the family of the *Elephants*. In a word, the animal, in our opinion, was a *Dugong with tusk-incisors*. We must, then, suppose that it had only one pair of anterior limbs, with five toes on each. As to the supposition that the animal was provided with a trunk, which might be presumed from the great nasal opening, the enlarged surfaces which surround it, and the size of the suborbital nerve, as far as it may be judged of from the size of the suborbital hole, we believe that that is at least doubtful, and that it is more probable that these dispositions bear relation to a considerable development of the upper lip and the necessary modification of the nostrils in an aquatic animal, as is equally the case in the dugong. We think even that the upper lip, by its immense development, embraced the lower one, and thus hid even the base of the tusks, and that the lower one was sufficiently small, as may be presumed from the chin-holes (trous mentonniers). After this, it is easy to

perceive that, of the two principal opinions which have been broached and discussed concerning this singular animal, we are much further from considering it a great species of *Edentata*, near the sloths, with Dr. Kaup, than from considering it as a tapir, as G. Cuvier did, from an examination of the molar teeth, the only parts then known. In fact, there is in our opinion much less distance, in the natural method, between a dugong and a tapir, than between a dugong and a sloth." In this note M. de Blainville has not taken into consideration that the head of the *Dinotherium*, as well as a phalanx which was found in the same locality, are referred by Professor Kaup to the same animal; but M. de Blainville does not believe that this phalanx really belonged to the *Dinotherium*. "In fact (says he), M. Lartet found with these same phalanges a portion of a tooth, which evidently indicates a great pangolin."

At the end of the reading, M. Duméril rose to confirm the views of M. de Blainville. He insisted particularly on the transversal form and great extent of the condyle of the lower jaw and of the articular fossa destined to receive it. He much regretted the loss of the zygomatic arch, the bases of which only remain on the jugal and temporal bones. "The curvatures of this arch," said he, "would have given ideas of the volume and force of the masseter and temporal muscles, which must have been considerable. It would be important to know them to compare them with those of the *Lamantin* on one side, and on the other with the *Megatherium*, whose skeleton is at Madrid. With regard to the phalanges, which are believed to be those of the *Dinotherium*, they are certainly analogous to those of the *Sloths*; but in the *Lamantin*, the ungual phalanx, which is in fact a double pulley with a mesial projection at the base, offers at its other extremity a single point with a sort of hood (capuchon) below: that is to say, inverse to that which is found in the great species of cats (*Felis*), and very different from those of the *Sloths* and the *Ant-eaters*."

In this statement there is one position that is rather staggering; and, indeed, we cannot but think it probable that M. de Blainville has not been quite accurately reported. He is made to observe that the articulation of the lower jaw is such that the only motions permitted should be those of elevation and depression, as in the *Carnivora*. Now that with true grinding teeth, like those of the *Dinotherium*, the jaws should be limited to the motions of elevation and depression, so admirably fitted for working the cutting edges of the scissor-teeth of the *Carnivora*, is almost inconceivable. We shall wait with some anxiety for the arrival of the head in this country, when we shall be able to ascertain whether there be not a convex eminence anterior to the transverse depression or glenoid cavity for the condyle, indicative of a horizontal motion of the jaw backwards and forwards, a mode of operation which would be well adapted to the transverse ridges of enamel on the molar teeth of *Dinotherium*. Without venturing to give any opinion as to the true position of this interesting genus in the animal series till an opportunity has been afforded of examining the skull itself, we may be permitted to observe, that the evidence on which M. de Blainville is stated to have rested for the cetaceous character of *Dinotherium* appears to us to be rather meagre, and hardly sufficient to warrant the conclusion.

DI'OCESSE, (*διοίκησις*, *diokésis*, literally 'administration') in the time of Constantine and afterwards was used to designate one of the civil divisions of the empire, but it is now used only in reference to ecclesiastical affairs. A diocese is a district over which the authority of a bishop extends. It is equivalent to BISHOPRICK.

Since the articles BISHOP and BISHOPRICK were written, a change has taken place in the diocesan divisions of England. The bishoprick of Bristol no longer exists. The county of Dorset, which, with the city of Bristol and a small district around, formed the diocese, is distributed between the sees of Salisbury and Exeter. The city of Bristol is annexed to the diocese of Gloucester, and the bishop of Gloucester is henceforth to be called bishop of Gloucester and Bristol. The former number of bishopricks being thus reduced, a new diocese has been formed for a new bishop, whose style is the bishop of Ripon. This diocese consists of the town and borough of Ripon and all such parts of the deaneries of the Ainsty and of Pontefract as adjoin the western boundaries of the liberty of the Ainsty and of the Wapentake of Barkston Ash, Osgoldcross and Staincross; and all that part of the county of York, which now forms

part of the archdeaconry of Richmond and diocese of Chester; and also the whole of the parish of Aldborough. This diocese is thus formed out of the dioceses of York and Chester.

These changes have been made in pursuance of 'an act for carrying into effect the reports of the commissioners appointed to consider the state of the established church in England and Wales, with reference to ecclesiastical duties and revenues, so far as they relate to episcopal dioceses, revenues and patronage.' Other changes in respect of the diocesan division of the country have been made, and still further changes are contemplated. Among these is the erection of a new bishoprick, of which the collegiate church of Manchester is to be the cathedral.

DIOCLES, a Greek mathematician, who is chiefly known by his invention of the cissoid. [CISSOID.]

DIOCLETIANUS, CAIUS VALERIUS, was born at Dioclea, in Dalmatia, some say at Salona, about 245 A. D. according to some, but others make him ten years older. His original name was Diocles, which he afterwards changed into Diocletianus. He is said by some to have been the son of a notary, by others the freedman of a senator named Anulinus. He entered the army at an early age, and rose gradually to rank; he served in Gaul, in Mœsia under Probus, and was present at the campaign against the Persians, in which Carus perished in a mysterious manner. Diocletian commanded the household or imperial bodyguards when young Numerianus, the son of Carus, was secretly put to death by Aper his father-in-law, while travelling in a close litter on account of illness, on the return of the army from Persia. The death of Numerianus being discovered after several days by the soldiers near Calchedon, they arrested Aper and proclaimed Diocletian emperor, who addressing the soldiers from his tribunal in the camp, protested his innocence of the death of Numerianus, and then upbraiding Aper for the crime, plunged his sword into his body. The new emperor observed to a friend that 'he had now killed the boar,' punning on the word Aper, which means a boar, and alluding to the prediction of a soothsayer in Gaul who had told him that he would become emperor after having killed a boar. (Vopiscus in *Hist. Aug.*) Diocletian, self-composed and strong-minded in other respects, was all his life an anxious believer in divination, which superstition led him probably to inflict summary punishment upon Aper with his own hands. He made his solemn entrance into Nicomedia in September, 284, which town he afterwards chose for his favourite residence. Carinus, the other son of Carus, who had remained in Italy, having collected a force to attack Diocletian, the two armies met at Margum in Mœsia, where the soldiers of Carinus had the advantage at first, but Carinus himself being killed during the battle by his officers, who detested him for his cruelty and debauchery, both armies joined in acknowledging Diocletian emperor, A. D. 285. Diocletian was generous after his victory, and, contrary to the common practice, there were no executions, proscriptions, or confiscations of property; he even retained most of the officers of Carinus in their places. (Aurelius Victor.)

Diocletian on assuming the imperial power found the empire assailed by enemies in various quarters, on the Persian frontier, on the side of Germany and of Illyricum, and in Britain; besides which a serious revolt had broken out in Gaul among the rural population, under two leaders who had assumed the title of emperor. To quell the disturbance in Gaul, Diocletian sent his old friend Maximianus, a native of Pannonia, and a brave but rude uncultivated soldier. Maximianus defeated the Bagaudi, for such was the name the rustic insurgents had assumed. In the year 286, Diocletian chose Maximianus as his colleague in the empire, under the name of Marcus Valerius Maximianus Augustus, and it is to the credit of both that the latter continued ever after faithful to Diocletian and willing to follow his advice. Maximianus was stationed in Gaul and on the German frontier to repel invasion; Diocletian resided chiefly in the East to watch the Persians, though he appears to have visited Rome in the early part of his reign. About 287 the revolt of Carausius took place. [BRITAIN.] In the following year Maximianus defeated the Germans near Treviri, and Diocletian himself marched against other tribes on the Rhætian frontier; the year after he defeated the Sarmatians on the lower Danube. In the same year, 289, peace was made between Carausius and the two emperors, Carausius being allowed to retain

possession of Britain. In 290 Maximianus and Diocletian met at Milan to confer together on the state of the empire, after which Diocletian returned to Nicomedia. The Persians soon after again invaded Mesopotamia and threatened Syria, the Quinquegentiani, a federation of tribes in the Mauritania Cæsariensis, revolted, another revolt under one Achillæus broke out in Egypt, and another in Italy under a certain Julianus. Diocletian thought it necessary to increase the number of his colleagues in order to face the attacks in the various quarters. On the 1st March, 292, or 291 according to some chronologists, he appointed Galerius as Cæsar, and presented him to the troops at Nicomedia. At the same time Maximianus adopted on his part Constantius called Chlorus. The two Cæsars repudiated their respective wives; Galerius married Valeria, Diocletian's daughter, adding to his name that of Valerianus; and Constantius married Theodora, daughter of Maximianus. Galerius was a native of Dacia, and a good soldier, but violent and cruel; he had been a herdsman in his youth, for which he has been styled, in derision, Armentarius. The two Cæsars remained subordinate to the two Augusti, though each of the four was entrusted with the administration of a part of the empire. Diocletian kept to himself Asia and Egypt; Maximianus had Italy and Africa; Galerius, Thrace and the Illyricum; and Constantius had Gaul and Spain. But it was rather an administrative than a political division. At the head of the edicts of each prince were put the names of all the four, beginning with that of Diocletian. Diocletian resorted to this arrangement probably as much for reasons of internal as of external policy. For nearly a hundred years before, ever since the death of Commodus, the soldiers had been in the habit of giving or selling the imperial crown, to which any general might aspire. Between thirty and forty emperors had been thus successively made and unmade, many of whom only reigned a few months. By fixing upon four colleagues, one in each of the great divisions of the empire, each having his army, and all mutually checking one another, Diocletian put a stop to military insolence and anarchy. The empire was no longer put up to sale, the immediate and intolerable evil was effectually cured, though another danger remained, that of disputes and wars between the various sharers of the imperial power; still it was a smaller danger and one which did not manifest itself so long as Diocletian remained at the helm. Writers have been very free of their censure upon this emperor for parcelling, as they call it, the empire; but this was the only chance there was of preventing its crumbling to pieces. Italy, and Rome, in particular, lost by the change: they no longer monopolized the wealth and power of the world, but the other provinces gained. The empire was much too large for one single man or a single central administration, especially under the dwindled influence of the Roman name, and amidst the numerous causes of local dissension and discontent, private ambition, social corruption, and foreign hostility, that had accumulated for three centuries, since the time of Augustus.

The new Cæsars justified Diocletian's expectations. Constantius defeated the Franks and the Alemanni, and soon after reconquered Britain. Galerius subjugated the Carpi, and transported the whole tribe into Pannonia. In the year 296, the Persians, under their king Narses, again invaded Mesopotamia and part of Syria. Galerius marched against them, but being too confident was defeated by superior numbers, and obliged to retire. On his meeting Diocletian, the emperor showed his dissatisfaction by letting Galerius walk for a mile, clad in purple as he was, by the side of his car. The following year Galerius again attacked the Persians, and completely defeated them, taking an immense booty. The wives and children of Narses, who were among the prisoners, were treated by Galerius with humanity and respect. Narses sued for peace, which was granted by Diocletian on condition of the Persians giving up all the territory on the right or western bank of the Tigris. This peace was concluded in 297, and lasted forty years. At the same time Diocletian marched into Egypt against Achillæus, whom he besieged in Alexandria, which he took after a siege of eight months, when the usurper and his chief adherents were put to death. Diocletian is said to have behaved on this occasion with unusual sternness. Several towns of Egypt, among others Busiris and Coptos, were destroyed. Constantine, the son of Constantius, who was educated at Nicomedia, accompanied the emperor in this expedition. Diocletian fixed the limits of the empire on that side at the

island of Elephantina, where he built a castle, and made peace with the neighbouring tribes, called by some Nubæ and by others Nabatæ, to whom he gave up the strip of territory which the Romans had conquered, of seven days' march above the first cataract, on condition that they should prevent the Blemmyes and Ethiopians from attacking Egypt. Maximianus in the mean time was engaged in putting down the revolt in Mauritania, which he effected with full success. For several years after this the empire enjoyed peace, and Diocletian and his colleagues were chiefly employed in framing laws and administrative regulations, and in constructing forts on the frontiers. Diocletian kept a splendid court at Nicomedia, which town he embellished with numerous structures. He, or rather Maximianus by his order, caused the magnificent Thermæ at Rome to be built, the remains of which still bear Diocletian's name, and which contained, besides the baths, a library, a museum, public walks, and other establishments.

In February 303 Diocletian issued an edict against the Christians, ordering their churches to be pulled down, their sacred books to be burnt, and all Christians to be dismissed from offices civil or military, with other penalties, exclusive, however, of death. Various causes have been assigned for this measure. It is known that Galerius had always been hostile to the Christians, while Diocletian had openly favoured them, had employed them in his armies and about his person; and Eusebius (*Hist. Eccles.* viii.) speaks of the prosperity, security and protection, which the Christians enjoyed under his reign. They had churches in most towns, and one at Nicomedia in particular under the eye of the emperor. Just before the edict was issued, Galerius had repaired to Nicomedia to induce Diocletian to proscribe the Christians. He filled the emperor's mind with reports of conspiracies and seditions. The imperial palace took fire, Constantine (*Oratio ad Cætum Sanctorum*) says, from lightning, and Galerius suggested to the emperor that it was a Christian plot. The heathen priests on their part exerted themselves for the same purpose. It happened that on the occasion of a solemn sacrifice in presence of the emperor, while priests were consulting the entrails of the victims, the Christian officers in the imperial retinue crossed themselves; upon which the priests declared that the presence of profane men prevented them from discovering the auspices. Diocletian who was very anxious to pry into futurity, became irritated, and ordered all his Christian officers to sacrifice to the gods under pain of flagellation and dismissal, which many of them underwent. Several oracles which he consulted gave answers unfavourable to the Christians. The church of Nicomedia was the first pulled down by order of the emperor. The rashness of a Christian who publicly tore down the imperial edict exasperated Diocletian still more: the culprit was put to a cruel death. Then came a second edict, ordering all magistrates to arrest the Christian bishops and presbyters, and compel them to sacrifice to the gods. This was giving to their enemies power over their lives, and it proved in fact the beginning of a cruel persecution, whose ravages were the more extensive in proportion to the great diffusion of Christianity during a long period of toleration. This was the last persecution under the Roman empire, and it has been called by the name of Diocletian. But that emperor had little share in it, beyond issuing the two edicts, which he did reluctantly and after long hesitation, according to Lactantius's acknowledgment: he fell ill a few months after, and on recovering from his long illness he abdicated. Galerius who had instigated the persecution, was the most zealous minister of it; the persecution raged with most fury in the provinces subject to his rule, and he continued it for several years after Diocletian's abdication, so that it might with more propriety be called the Galerian persecution. The countries under the government of Constantius suffered the least from it. (Eusebius, *Hist. Eccles.*; Lactantius *de Mort. Persecut.*; and Constantine's *Oration*, above quoted, as given by Eusebius.)

In November of that year, 303, Diocletian repaired to Rome, where he and Maximianus enjoyed the honour of a triumph, followed by festive games. This was the last triumph that Rome saw. The populace of that city complained of the economy of Diocletian on the occasion, who replied that moderation and temperance were most required where the censor was present. They vented their displeasure in jibes and sarcasms, which so hurt Diocletian that he left Rome abruptly in the month of December for

Ravenna, in very cold weather. In this journey he was seized by an illness which affected him the whole of the following year, which he spent at Nicomedia. At one time he was reported to be dead. He rallied however in the spring of 305, and showed himself in public, but greatly altered in appearance. Galerius soon after came to Nicomedia, and it is said that he persuaded and almost forced Diocletian to abdicate. Others say that Diocletian did it spontaneously. On the 1st of May he repaired with his guards to a spot, three miles out of Nicomedia, where he had thirteen years before proclaimed Galerius as Cæsar, and there addressing his officers and court, he said that the infirmities of age warned him to retire from power, and to deliver the administration of the state into stronger hands; he then proclaimed Galerius as Augustus, and Maximinus Daza as the new Cæsar. Constantine, who has given an account of the ceremony, which is quoted by Eusebius in his life of that prince, was present, and the troops fully expected that he would be the new Cæsar; when they heard another mentioned, they asked each other whether Constantine had changed his name. But Galerius did not leave them long in suspense: he pushed forward Maximinus and showed him to the assembly, and Diocletian clothed him with the purple vest, after which the old emperor returned privately in his carriage to Nicomedia, and immediately after set off for Salona in Dalmatia, near which he built himself an extensive palace by the sea-shore, in which he lived for the rest of his life, respected by the other emperors, without cares and without regret. Part of the external walls which inclosed the area belonging to his palace and other buildings still remain, with three of the gates, as well as a temple, which is now a church at Spalatro, or Spalato, in Dalmatia, a comparatively modern town, grown out of the decay of the antient Salona, and built in great part within the walls of Diocletian's residence, from the name of which 'Palatium' it is believed that 'Spalato' is derived. Descriptions of the remains of the palace are given in Spon, Fortis, Cassas, and Adams's splendid engravings, London, 1764. At the same time that Diocletian abdicated at Nicomedia, Maximianus, according to an agreement between them, performed a similar ceremony at Milan, proclaiming Constantius as Augustus, and Severus as Cæsar. Both Severus and Maximinus Daza were inferior persons, and creatures of Galerius, who insisted upon their nomination in preference to that of Maxentius and Constantine, whom Diocletian had at first proposed. Maximianus retired to his seat in Lucania, but not being endowed with the firmness of Diocletian, he tried some time after to recover his former power, and wrote to his old colleague to induce him to do the same. 'Were you but to come to Salona,' answered Diocletian, 'and see the vegetables which I grow in my garden with my own hands, you would no longer talk to me of empire.' In his retirement he used to observe to his associates how difficult it is even for the best-intentioned man to govern well, as he cannot see everything with his own eyes, but must trust to others who often deceive him: 'Bonus, cautus, optimus, venditur Imperator' (Vopiscus). Once only he left his retirement to meet Galerius in Pannonia for the purpose of appointing a new Cæsar, Licinius, in the room of Severus, who had died. Licinius however did not prove grateful, for after the death of Galerius, A.D. 311, he ill-treated his widow, Valeria, Diocletian's daughter, who then with her mother, Prisca, took refuge in the territories of Maximinus Daza. The latter offered to marry Valeria, but on her refusal exiled both her and her mother into the deserts of Syria, and put to death several of their attendants. Diocletian remonstrated in favour of his wife and daughter, but to no purpose, and his grief on this occasion probably hastened his death, which took place at his residence near Salona in July, 313. In the following year his wife and daughter were put to death by order of Licinius.

Diocletian ranks among the most distinguished emperors of Rome; his reign of twenty-one years was upon the whole prosperous for the empire, and creditable to the Roman name. He was severe, but not wantonly cruel, and we ought to remember that mercy was not a Roman virtue. His conduct after his abdication shows that his was no common mind. The chief charge against him is his haughtiness in introducing the Oriental ceremonial of prostration into the Roman court. The Christian writers, and especially Lactantius, have spoken unfavourably of him; but Lactantius cannot be implicitly trusted. Of the regular his-

torians of his reign we have only the meagre narratives of Eutropius and Aurelius Victor, the others being now lost; but notices of Diocletian's life are scattered about in various authors, Libanius, Vopiscus, Eusebius, Julian in his *Cæsars*, and the contemporary panegyrists, Eumenius and Mamertinus. His laws or edicts are in the Code. Among other useful reforms, he abolished the frumentarii, or licensed informers, who were stationed in every province to report any attempt at mutiny or rebellion, and who basely enriched themselves by working on the fears of the inhabitants. He also reformed and reduced the number of the insolent Prætorians, who were afterwards totally disbanded by Constantine.

Coin of Diocletian.

British Museum. Actual Size. Copper. Weight, 167½ grains.

DIODATI, JEAN, was born in Geneva in 1576, of a family originally from Lucca. His progress in learning was so rapid, that Beza procured him to be appointed professor of Hebrew in the University of Geneva when he was but twenty-one years of age. In 1608 he was made pastor, or parish minister, and in the following year professor of theology. While travelling in Italy about 1608, he became acquainted at Venice with the celebrated Sarpi and his friend Father Fulgenzio, both antagonists of the Court of Rome, and there appears to have been some talk and correspondence between them about attempting a religious reform in Italy, but Sarpi's caution and maturer judgment checked the fervour of the other two. Diodati afterwards translated into French and published at Geneva Sarpi's *History of the Council of Trent*. In consideration of his theological learning, he was sent by the clergy of Geneva on several missions, first to the reformed churches in France, and afterwards to those of Holland, where he attended the Synod of Dort 1618-19, and although a foreigner, he was one of the divines appointed to draw up the acts of that assembly. He fully concurred in the condemnation of the Arminians, or Remonstrants as they were called. Diodati was also distinguished as a preacher; in his sermons he spoke with conscientious frankness, without any regard to worldly considerations. He published an Italian translation of the Bible in 1607, and afterwards a French translation which was not completed till 1644, having met with considerable opposition from the clergy of Geneva. Diodati died at Geneva in 1649. He wrote also, '*Annotationes in Biblia*,' fol. Geneva 1607, which were translated into English, and published in London, 1648, and numerous theological and controversial works, among others, '*De Fictitio Pontificiorum Purgatorio*,' 1619; '*De justa Secessione Reformatorum ab Ecclesia Romana*,' 1628; '*De Ecclesia*;' '*De Antichristo*,' &c. Senebier, in his '*Histoire Littéraire de Genève*,' gives a catalogue of Diodati's works. He also wrote an answer to the ecclesiastical assembly in London, in reply to letters addressed to him by some members of that assembly, and which was published in Newcastle, 1647. In it Diodati deploras the troubles both religious and civil which had broken out in England, and deprecates the continuation of a struggle in which men, 'having lost sight of the original causes that began the war, were excited by the new mutual injuries freshly done or received, the two parties being far more divided by an odious difference of reproachful names than really by the cause itself.' Diodati translated also into French Edwin Sandy's '*Account of the State of Religion in the West*,' Geneva, 1626.

DIODORUS, a Greek historian born at Agyrium in Sicily. (*Biblioth. Hist.*, lib. i. c. 5.) Our principal data for the chronology of his life are derived from his own work. It appears that he was in Egypt about the 180th olympiad, 60 B.C. (*Bibl. Hist.* i. c. 44, comp. i. c. 83); that his history was written after the death of Julius Cæsar; that it ended with the Gallic war of that general, and that he spent thirty years in writing it. (*Biblioth. Histor.* i. c. 4, comp. v. c. 21 and 25.) In addition to this, Suidas mentions that he lived in the time of Augustus, and he is named under the year 49 B.C. by Jerome in the Chronicle of Eusebius. The title

of the great work of Diodorus is the '*Historical Library*' (*βιβλιοθήκη ιστορική*) or '*The Library of Histories*' (*ἡ τῶν ιστοριῶν βιβλιοθήκη*); and it would therefore seem to have been intended by the author as a compilation from all the different historical works existing in his time. It was divided by him into forty books, and comprehended a period of 1138 years, besides the time preceding the Trojan war. (*Biblioth. Hist.* i. c. 5.) The first six books were devoted to the fabulous history anterior to this event, and of these the three former to the antiquities of barbarian states, the three latter to the archæology of the Greeks. But the historian, though treating of the fabulous history of the barbarians in the first three books, enters into an account of their manners and usages, and carries down the history of these people to a point of time posterior to the Trojan war; thus in the first book he gives a sketch of Egyptian history from the reign of Menes to Amasis. In the eleven following books he detailed the different events which happened between the Trojan war and the death of Alexander the Great, and the remaining twenty-three books contained the history of the world down to the Gallic war and the conquest of Britain. (*Biblioth. Hist.* i. c. 4.) Diodorus asserts that he bestowed the greatest possible pains on his history, and had travelled over a considerable part of Europe and Asia in order to prosecute his investigations with the greatest advantage. He resided some time at Rome, and, having made himself familiar with the Latin language, was enabled to consult the Roman historians in the originals. He objects to the custom so common among Greek and Roman writers of interlarding their narratives with fictitious speeches, to which he says (*Bib. Hist.* lib. xx. init.), they made the whole history a mere appendix, although he seems to have fallen into this fault in the xxi. book (Niebuhr, *Hist. Rom.* iii., note 848); but on the other hand he thought it the duty of an historian never to omit a suitable opportunity of pronouncing merited praise or blame. (*Bibl. Hist.*, lib. xi.) Of the forty books of Diodorus's History we possess only fifteen, namely books i.—v. and books xi.—xx., but we have many fragments of the twenty-five others, to which important additions have recently been made from MSS. in the Vatican library.

With regard to the historical value of the *Bibliotheca* and the merits of the author, the most discrepant opinions have been entertained by modern writers. The Spanish scholar, Vives, called him a mere trifler, and Jean Bodin accused him, in no sparing terms, of ignorance and carelessness, while, on the other hand, he has been defended and extolled by many eminent critics as an accurate and able writer. The principal fault of Diodorus seems to have been the too great extent of his work. It was not possible for any man, living in the time of Augustus, to write an unexceptionable universal history: indeed it may be doubted whether any one writer could, even at the present day, successfully accomplish so difficult a task, and Sir Walter Raleigh's '*History of the World*' is a proof that men of the greatest ability are liable to failure in such an attempt. It is not, then, a matter of surprise that Diodorus, who does not appear to have been a man of superior abilities, should have fallen into a number of particular errors, and should have placed too much reliance on authorities sometimes far from trustworthy. Wherever he speaks from his own observations he may, perhaps, generally be relied on, but when he is compiling from the writings of others he has shown little judgment in his selection, and has in many cases proved himself incapable of discriminating between the fabulous and the true. In some instances, as in his account of Egypt (see Description of the Tomb of Osymandyas), it is impossible to say whether he is speaking as an eye-witness or upon the report of others. We must not blame him for giving a Greek colouring to the manners of other nations which he describes, for it was the common practice of Greek writers to do so, and he has not erred so much in this respect as Dionysius of Halicarnassus. Although he professes to have paid great attention to chronology, his dates are frequently and obviously incorrect. (See Dodwell's *Annal. Thucyd.* and Clinton's *Fasti Hellenici*, ii., p. 259 and elsewhere; Niebuhr, *Hist. Rome*, ii., and note 1281.) However, we are indebted to him for many particulars which but for him we should never have known, and we must regret that we have lost the last and probably most valuable portion of his works, as even by the fragments of them which remain we are enabled in many places to correct the errors of Livy. The style of Diodorus, though not very pure or elegant, is sufficiently

perspicuous, and presents few difficulties, except where the MSS. are defective, as is frequently the case. (Niebuhr, *Hist. Rome*, vol. iii. note 297 and elsewhere.)

The best editions of Diodorus are Wesseling's, Amstel., 1745, two vols. fol.; that printed at Deux-Ponts, 1793—1801, and Dindorf's, Lips., 1829—33, five vols. 8vo., which contains the Vatican Excerpta. There is also a smaller edition by Dindorf in four vols. 12mo., Lips., 1826. Diodorus has been translated into French by Terrasson, and two or three years ago a new translation by Miot appeared at Paris. A German translation of Diodorus was begun by F. And. Stroth (1782-1785), and finished by T. F. Sal. Kaltwasser (1786-1787). Amyot translated into French books xi. to xvii. of Diodorus's History.

DICECIA, the twenty-second class in the artificial method used by Linnæus in arranging plants. It comprehends such genera as have male or stamen-bearing flowers on one plant, and female or pistil-bearing flowers on another, as willows. Hence all plants having the sexes thus distinguished are called dicecious.

DIO'GENES, the Cynic philosopher, was the son of Hicesius, a money-changer of Sinope. His father and himself were expelled from their native place on a charge of adulterating the coinage, or, according to another account, Hicesius was thrown into prison and died there, while Diogenes escaped to Athens. On his arrival at that city, he betook himself to Antisthenes, the Cynic, who repulsed him rudely according to his custom, and even on one occasion threatened to strike him. 'Strike me,' said the Sinopian, 'for you will never get so hard a stick as to keep me from you while you speak what I think worth hearing.' The philosopher was so pleased with this reply that he at once admitted him among his scholars. Diogenes was soon distinguished for his extraordinary neglect of personal conveniences, and by a sarcastic and sneering petulance in all that he said. He was dressed in a coarse double robe, which served him as a cloak by day and a coverlet by night, and carried a wallet to receive alms of food. His abode was a cask in the temple of Cybele. In the summer he rolled himself in the burning sand, and in the winter clung to the images in the street covered with snow, in order that he might accustom himself to endure all varieties of weather. A great number of his witty and biting apophthegms are detailed by his namesake and biographer (Diog. Laërt., vi., c. 2). He became acquainted with Alexander the Great, who bade him ask for whatever he wanted. 'Do not throw your shadow upon me,' was the Cynic's only request. It is reported that Alexander was so struck with his originality that he exclaimed, 'Were I not Alexander, I would wish to be Diogenes.' Being taken by a piratical captain named Scirpalus, while sailing from Athens to Ægina, he was carried to Crete, and there sold to Xenias, of Corinth, who took him home to educate his children. He discharged the duties of this situation so faithfully and so successfully, that Xenias went about saying that a good genius had come into his house; and he was so well treated by his master that he refused an offer on the part of his friends to ransom him from slavery. He spent his time principally in the Cranium, a gymnasium near Corinth, where he died in the same year, and, according to one account, on the same day with Alexander the Great (323 B.C.), at the advanced age of 90 years. A number of works attributed to him are mentioned by Diogenes Laërtius, but none of them are extant. For the general doctrines of the sect to which Diogenes belonged, the reader may consult the article **CYNICS**. The following are a few of the particular opinions ascribed to him by his biographer. He thought exercise (*ἀσκησις*) was indispensable, and able to effect anything; that there were two kinds of exercise, one of the mind and the other of the body, and that one of these was of no value without the other. By the cultivation of the mind he did not mean the prosecution of any science or the acquirement of any mental accomplishment; all such things he considered as useless; but he intended such a cultivation of the mind as might serve to bring it into a healthy and virtuous state, and produce upon it an effect analogous to that which exercise produces upon the body. He adopted Plato's doctrine, that there should be a community of wives and children, and held with the Dorian lawgivers, that order (*κόσμος*) was the basis of civil government.

DIO'GENES of Apollonia, so called from his birth-place, a town in Crete, was a pupil of Anaximenes and a contemporary of Anaxagoras. The years in which

he was born and died are not known, as is the case also with his master Anaximenes. But the birth-year of his contemporary and fellow-pupil Anaxagoras is known to be 500 B.C.; and Diogenes would most probably be about the same age, or perhaps rather younger. Sidonius Apollinaris (xv. 91) speaks of Diogenes as younger than Anaxagoras, — '*junior collega Anaxagoræ*.' Schleiermacher, who is followed by Schaubach, the editor of the fragments of Anaxagoras, affirms from the internal evidence of the fragments of the two philosophers, that Diogenes preceded Anaxagoras. But Diogenes might have written before Anaxagoras, and yet have been his junior, as we know was the case with Empedocles. (Aristotle *Met.* i. iii., p. 843 B.)

Diogenes followed Anaximenes in making air the primal element of all things, that out of which the whole material universe was formed; but he invested this air with the property of intelligence, or with what is called by St. Augustin a divine virtue, thus approximating but not attaining to the system of Anaxagoras. It was reserved for this last philosopher to separate mind from matter. 'As the contemplation of animal life,' says Mr. Thirlwall, 'had led Anaximenes to adopt air as the basis of his system, a later philosopher, Diogenes of Apollonia, carried this analogy farther, and regarded the universe as issuing from an intelligent principle, by which it was at once vivified and ordered — a rational as well as sensitive soul — still without recognizing any distinction between matter and mind.' (*Hist. of Greece*, vol. ii., p. 134.) Cicero (*de Nat. Deor.*, i. 12) represents Diogenes as making air his deity.

He wrote several books on Cosmology (*περὶ φύσεως*); and the first sentence of his work is given by Diogenes Laertius in two places (vi. 81; ix. 57). The fragments which remain have been recently collected and edited by Panzerbeiter.

There is an essay on the philosophy of Diogenes, by Schleiermacher, in the *Memoirs of the Berlin Academy* for 1815; and a contribution to the chronology of his life in an article on the early Ionic philosophers, by Mr. Clinton, in the *Philological Museum*, vol. i., p. 92. For general information concerning him the reader is referred to Diogenes Laertius, ix. 9; Bayle's *Dictionary*; and Fabricii *Bibliotheca Græca*, ed. Harles, vol. ii., p. 656.

DIO'GENES, surnamed Laërtius, because he was born at Laërtes, in Cilicia, is well known as the biographer of the Greek philosophers. But though he has described the lives of others, he has given us no account of himself, and we know nothing about him. It is supposed that he lived in the reign of Severus or Caracalla, and that he was an Epicurean. The work by which Diogenes is known is a crude contribution towards the history of philosophy. It contains a brief account of the lives, doctrines, and sayings of most persons who had been called philosophers; and though the author is evidently a most unfit person for the task which he imposed upon himself, and has shown very little judgment and discrimination in the execution, the book is useful as a collection of facts which we could not otherwise have learned, and entertaining as a sort of *omniana* on the subject. The article on Epicurus is valuable as containing some original letters of that philosopher, which comprise a pretty satisfactory epitome of the Epicurean doctrines, and are very useful to the readers of Lucretius. The most convenient edition of Diogenes is that by H. G. Hübner, Lips., 1828-31, in two volumes octavo.

DIOIS, the territory in France of which Die was the capital. [DAUPHINE; DRÔME.]

DIOME'DEA. [ALBATROSS.]

DION, of Syracuse, son of Hipparinus, one of the chief men in that city, lived under the reigns of both the Dionysii. He was originally introduced to Dionysius the elder, by his sister Aristomache, one of the king's wives, but his own merit appears afterwards to have gained him so much favour at court, that he could speak to Dionysius with the freedom of an equal. He had early become the disciple of Plato whom Dionysius had invited to Syracuse, and Plato is said to have considered him the most ardent of his pupils. Soon after his accession, the younger Dionysius began to show the effects of an imperfect and vicious education, while in private he abandoned himself to all kinds of excesses. The prospects of his country roused Dion, and he endeavoured to counteract the errors and to supply the deficiencies of the tyrant by prudent counsels and exhortations. Among other things he advised him to invite Plato to revisit the Syracusan court, setting forth the advantages

which he would derive from his conversation and knowledge. Dionysius wrote a letter of invitation, but the philosopher had not forgotten the treatment which he had received from the tyrant's father, and it was with the utmost difficulty that he was prevailed on to go. The presence of Plato was dreaded by the dissolute courtiers who surrounded Dionysius, and to counteract any influence he might have, they obtained the recall of Philistus, whose talents and tyrannical tendencies they thought were likely to be a match for the philosopher. The enemies of Dion availed themselves of the same opportunity to insinuate suspicions of Dion's loyalty, and succeeded in procuring his banishment. He went first to Italy and then to Greece, where he received the highest honours. Dionysius however endeavoured to embitter his exile, and soon confiscated his lands and effects, and forced his wife to marry another person. Dion no sooner heard of this outrage, than he determined to make an effort to expel the tyrant. Though dissuaded by Plato, he began to raise troops privately, and at last assembled his forces to the number of about eight hundred in the island of Zacynthus, whence he sailed to Sicily. On landing, he found that Dionysius was absent in Italy, and he was accordingly received by the people with great joy. Dionysius on his return to Sicily, made some fruitless attempts to regain his influence, but after several defeats was forced to quit the island for Italy. Dion, however, did not long enjoy the favour of his countrymen, and by the influence of Heraclides, who estranged the minds of the people from him, he was obliged to leave Sicily; he was afterwards recalled, but was treacherously murdered, B.C. 354, at about fifty-five years of age, by his supposed friend Calippus, an Athenian. His death was generally regretted, and in honour of his high courage and patriotism a monument was raised to him at the public expense. (Diodorus Siculus xvi. 6—20; Plutarch, *Life of Dion*; Nepos, *Life of Dion*.)

DION CASSIUS COCCEIANUS, or Cocceius, was the son of Cassius Apronianus, a Roman Senator, and born at Nicæa in Bithynia about A.D. 155. On his mother's side he was descended from Dion Chrysostom, and it was from this branch of his family that he took the name of Dion. Thus though he was on his mother's side of Greek descent, and though in his writings he adopted the then prevailing language of his native province, he must be considered as a Roman. Under Commodus he lived in Rome, where he enjoyed the rank of Senator. After the death of Septimius Severus and Caracalla, under whom he held no public office, he was made governor of Smyrna and Pergamus by Macrinus. He was afterwards consul and proconsul in the provinces of Africa and Pannonia, probably under Alexander Severus (Suidas *Δίων*), who esteemed him so highly as to make him consul for the second time with himself. In his old age he is said to have returned to his native country. (Photius, *Dion Cassius*.)

Dion wrote a History of Rome in Greek, from the arrival of Æneas in Italy and the foundation of Alba and Rome to A.D. 229. To the time of Julius Cæsar his history was only a rapid sketch, but from that date and more particularly from the time of Commodus, when he is a contemporary writer, his narrative is very complete. Of the first 36 books there are only fragments extant: but there is a considerable fragment of the 35th book on the war of Lucullus against Mithridates, and of the 36th, on the war with the Pirates and the expedition of Pompey against Mithridates. The following books to the 54th inclusive are nearly all entire: they comprehend a period from B.C. 65 to B.C. 10, or from the Eastern campaign of Pompey and the death of Mithridates to the death of Agrippa. The 55th book has a considerable gap in it. The 56th to the 60th, both included, which comprehend the period from A.D. 9 to A.D. 54, are complete, and contain the events from the defeat of Varus in Germany to the reign of Claudius. Of the following 20 books we have only fragments, and the meagre abridgment of Xiphilinus. The 80th or last book comprehends the period from A.D. 222 to A.D. 229, in the reign of Alexander Severus. The abridgment of Xiphilinus, as now extant, commences with the 35th, and continues to the end of the 80th book: it is a very indifferent performance.

The fragments of the first 36 books, as now collected, are, 1, those called Valesiana, which were collected by Henri of Valois from various Scholiasts, Lexicographers and grammarians. 2, The Fragment a Peiresciana, taken from the great work or compilation of Constantinus Porphyrogen-

netus. [BYZANTIUM, p. 81.] 3, Fragment a Ursiniana, also taken from the same compilation of Constantinus Porphyrogenetus. 4, Excerpta Vaticana by Mai, which contain fragments of books 1—35 and 61—80, have been published in the second volume of the Scriptorum Veterum Nova Collectio, pp. 135—233. To these are added the fragments of an unknown continuator of Dion (pp. 234—246), which go down to the time of Constantine. Other fragments from Dion, belonging chiefly to the first 35 books, also published in the same collection (pp. 527—567), were found by Mai in two Vatican MSS., which contain a sylloge or collection made by Maximus Planudes.

The annals of Zonaras contain numerous extracts from Dion.

Dion as an historian is not characterized by any great critical power or judgment: indeed his own remarks are sometimes trifling. His style is generally clear, though there are occasionally obscure passages where there appears to be no corruption in the text. His diligence is unquestionable, and from his opportunities he was well acquainted with the circumstances of the empire during the period for which he is a contemporary authority, and indeed we may assign a high value to his history of the whole period from the time of Augustus to his own age. Nor is his history without value for the earlier periods of Roman history, in which though he has fallen into errors, like all the Greek and Roman writers, who have handled the same obscure subject [DICTATOR], he still enables us to correct some erroneous statements of Livy and Dionysius.

Other writings are attributed to Dion; among them a life of Arrian by Suidas (*Δίων*).

The first edition of the Greek text of Dion was by R. Stephens, Paris 1548, fol. from one MS., and that very incorrect and defective. Between this edition and that of Reimar there were several editions. J. Alb. Fabricius undertook a new edition of Dion, but dying before he had completed his labour, his papers came into the hands of H. S. Reimar, his son in law, who published the new edition at Hamburg 1751—1752, 2 vols. fol. with a Latin translation. The edition of Reimar is valuable, as he availed himself of the labours of all his predecessors, arranged the fragments in order, and improved the text and translation, to which he added notes. Some fragments were afterwards discovered in a MS. in the library of St. Mark, by Morelli, and published by him at Bassano in 1798, 8vo. They were reprinted at Paris in 1800, fol., in a form to accompany the edition of Reimar.

The small Tauchnitz print of Dion Cassius, 4 vols. 16mo., contains the fragments. The most recent and perhaps most useful edition is by F. W. Sturz, Leipzig, 1824, 1825, 8 vols. 8vo. There are several German translations of Dion Cassius: the most recent is by F. Lorentz, Jena, 1826, 4 vols. 8vo. There is an old French translation from the Latin, by Dérozières, 1542, fol.

DION, surnamed Chryóstomus, or the Golden-mouthed, on account of the beauty of his style, the son of Pasicrates, a man of consideration at Prusa in Bithynia, was a sophist and stoic. He was in Egypt when Vespasian, who had been proclaimed emperor by his own army, came there, and was consulted by that prince on the proper course to be adopted under the circumstances. Dion had the candour, or, as some may think, the want of judgment, to advise him to restore the republic. Afterwards he resided for some years at Rome, till one of his friends, having engaged in a conspiracy against Domitian, was condemned to death, and Dion, fearing for himself, fled to the modern Moldavia, where he remained till the tyrant's death, labouring for his subsistence with his own hands, and possessing no books but the *Phædon* of Plato and Demosthenes *περί Πανάγορας βίης*. Domitian having been assassinated, the legions quartered on the Danube were about to revolt, when Dion got upon an altar and harangued them so effectually that they submitted to the decision of the senate. Dion was in high favour with Nerva and Trajan, and when the latter triumphed after his Dacian victories the orator sat in the emperor's car in the procession. He returned to Bithynia, where he spent the remainder of his life. Accusations of peculation and treason were brought against him, but rejected as frivolous. Dion died at an advanced age, but it is not known in what year. We have eighty orations attributed to him, which are very prettily written, but not of much intrinsic value. The best edition is that of Reiske, 2 vols. 8vo., Lips., 1784. The name Cocceianus, which Pliny (Epist. x. 85, 86) gives

to Dion, probably refers to his connection with the Emperor Cocceius Nerva.

DIONÆA, a most singular herbaceous plant, remarkable for the irritability of its leaves, which, when brushed against by an insect, will suddenly close upon it and hold it fast, whence it is often called Venus's Fly-trap and the Carolina Catchfly plant. It is botanically related to the Drosera, or sundew, which has also the property of seizing insects by its viscid hairs, but differs so much as to have led some botanists to doubt whether it really belongs to the same natural order. Its flower-branches, for example, are not rolled up before they unfold, but have a straight æstivation; the placenta of the fruit are stationed at the base of the one-celled capsule; the stigma is a lacerated fringed brush, and there are other differences; but upon the whole, it is probably a genuine portion of the droseraceous order.

Dionæa has broad stalked leaves, spreading in a circle round the bottom of the flower stem. Its flower stem rises straight to the height of six or eight inches, and is terminated by a cyme of small greenish-white flowers, each of which has a calyx of five sepals, five wedge-shaped notched petals, ten hypogynous stamens, and an ovary shaped like some of the old German wine-bottles, round at the bottom, and tapering suddenly into a short neck or style. The best modern account of its habits has been given by Mr. M. A. Curtis, who thus speaks of it from his observations upon the plant in its native bogs. 'The Dionæa muscipula is found as far north as Newbern, N. Carolina, and from the mouth of Cape Fear River to Fayetteville. It is stated moreover to grow along the lower branches of the Santee, in S. Carolina; and it is not improbable that it inhabits the savannahs, more or less abundantly, from the latter place to Newbern. It is found in great plenty for many miles around Wilmington in every direction. The leaf, which is the only remarkable part, springs from the root, spreading upon the ground at a little elevation above it. It is composed of a broad stalk, like the leaf of an orange-tree, winged, and from two to four inches long, which at the end suddenly expands into a thick and somewhat rigid blade, the two sides of which are semicircular, about two-thirds of an inch across, and fringed round their edges with somewhat rigid cilia, or long hairs, like eye-lashes. The leaf, indeed, may be aptly compared to the two upper eyelids, joined at their bases. Each portion of the leaf is a little concave on the inner side, where are placed three delicate, hair-like organs, in such an order that an insect can hardly traverse it without interfering with one of them, when the two sides suddenly collapse and enclose their prey, with a force surpassing an insect's attempts to escape. The fringe or hairs of the opposite sides interlace, like the fingers of the two hands clasped together. The sensitiveness resides only in these hair-like processes on the inside, as the leaf may be touched or pressed in any other part without sensible effects. The little prisoner is not crushed and suddenly destroyed, as is sometimes supposed; for I have often liberated captive flies and spiders, which sped away as fast as fear or joy could hasten them. At other times, I have found them enveloped in a fluid of mucilaginous consistence, which seems to act as a solvent, the insects being more or less consumed by it. This circumstance has suggested the possibility of the insects being made subservient to the nourishment of the plant, through an apparatus of absorbent vessels in the leaves. But as I have not examined sufficiently to pronounce on the universality of this result, it will require further observation and experiment on the spot to ascertain its nature and importance.

'It is not to be supposed, however, that such food is necessary to the existence of the plant, though, like compost, it may increase its growth and vigour. But however obscure and uncertain may be the final purpose of such a singular organization, if it were a problem to construct a plant with reference to entrapping insects, I cannot conceive of a form and organization better adapted to secure that end, than are found in the Dionæa muscipula. I therefore deem it no credulous inference that its leaves are constructed for that specific object, whether insects subservise the purpose of nourishment to the plant or not. It is no objection to this view that they are subject to blind accident, and sometimes close upon straws, as well as insects. It would be a curious vegetable, indeed, that had a faculty of distinguishing bodies, and recoiled at the touch of one, while it quietly submitted to violence from another. Such capricious sensitiveness is not a property of the vege-

table kingdom. The spider's net is spread to ensnare flies, yet it catches whatever falls upon it; and the ant-lion is roused from his hiding-place by the fall of a pebble; so much are insects, also, subject to the blindness of accident.' We may add, with reference to the American author's conjecture that the trapped insects may contribute to the nourishment of the leaf of Dionæa, that leaves have actually been fed with chopped meat, and have been found to become more healthy and vigorous in consequence of this artificial stimulus.

DIONYSIA (Διονύσια), festivals held in honour of the god Dionysus, or Bacchus. The most important of such festivals, and those which alone deserve to be specially mentioned, were held at Athens and in Attica; and these are important by reason of their being the occasions on which all the dramatic exhibitions of the Athenians took place. Both the tragedy and comedy of the Athenians arose ultimately from parts of ceremonies, which prevailed in very early times among the Greeks, at the festivals of Dionysus (Aristot. *Poet.* 4. 14); and it is alike a consequence and a proof of this origin, that the dramatic exhibitions and contests among the Athenians, from the earliest to the latest times at which we can trace them, always took place at some one of the Attic Dionysia.

These Attic Dionysia were four in number. Enumerated in the order of time, according to the Attic year, they were: 1, The Lesser or Rural Dionysia, held in the month Poseideon; 2, The Lenæa, held in the month Gamelion; 3, The Anthesteria, held in the month Anthesterion; and 4, The Great or City Dionysia, held in the month Elaphebolion. They were held in four consecutive months, the first of which, Poseideon, coincides with part of December and part of January, and the last, Elaphebolion, with part of March and part of April.

Until recently, the number of the Attic Dionysia was always supposed to be three; the fourth being made to disappear by identifying the Lenæa, the second which we have named, either with the Anthesteria or with the Rural Dionysia. But the incorrectness of both these opinions, and the separate existence of the Lenæa, have been established unanswerably by Boeckh, the author of the *Public Economy of Athens*, in an essay published in 1819 in the *Transactions of the Berlin Academy of Sciences*. It is not in our power to enter into any account of the argument contained in this essay; but the reader may see an abstract of the essay in an article on the Attic Dionysia by Mr. Thirlwall, in the *Philological Museum* (vol. ii. p. 273), and a very brief notice in Buttman's second *Excursus*, in his edition of Demosthenes's oration against Midias. Viewed in its relation to the Attic Drama, the question which is handled in Boeckh's essay, is not unimportant.

We proceed to speak of these festivals separately, and in the order in which they occurred in the Attic year.

1. *The Rural or Lesser Dionysia*, was a festival celebrated all over Attica, the other three being confined to Athens. It was a festival of the vintage, and though it may appear to have been held somewhat late in the year (in the latter-part of December), was not held later than the vintage now takes place, in a more rigorous climate, in some of the vineyards producing the Tokay wine. (*Phil. Mus.*, vol. ii., p. 296.) The Rural Dionysia were celebrated by means of separate festivals in all the demes of Attica; the expenses of these separate festivals fell on the several demes; and the performances, processions, and banquets, of which the festivals consisted, were under the superintendence of the several demarchs. It is inferred from the law of Evagoras, cited by Demosthenes (*Mid.* p. 517), and an inscription contained in Boeckh's *Public Economy of Athens* (App. viii.), that Athens joined, on the occasion of the Rural Dionysia, in the festival celebrated at Piræus. At the dramatic performances of these rural festivals, plays that had before been represented either at the Lenæa or the Great Dionysia, used to be repeated. Of the procession, in which was carried the phallus, and in which was sung the phallic hymn, there is a sketch in miniature in the *Acharnians* of Aristophanes (v. 230, fol.).

2. *The Lenæa*, so called from a wine-press (ληνός), whose erection, in an inclosure called for the same reason *Lenæum*, lying originally a little out of the city and near a marsh (λίμνη), it was supposed to commemorate, may, like the Rural Dionysia, be considered a vintage-festival. Boeckh thinks that a festival which went by the name of *Ambrosia* was the same with the Lenæa; and he supposes, in order

to explain the relation of this festival to the Rural Dionysia, that, after the general vintage had ended, the fruit of some vines was still reserved to a later season, and that from this fruit was extracted a nectar, which being used on the occasion of, and serving to distinguish, this festival, might have given rise to the name *Ambrosia*. (See *Phil. Mus.*, vol. ii., p. 297.) The Lenæa were celebrated also among the Ionian states in Asia Minor, they having carried over with them at their migration the custom of the mother-country; and the Attic month Gamelion, in which the Lenæa were held, received in the Ionian calendar the name Lenæon. In Athens, the Lenæa were under the superintendence of the king-archon, and were celebrated with a public banquet at the expense of the state, and with dramatic exhibitions. As regards these last, we find that they consisted chiefly of new comedies. There are, however, instances of tragedies represented at the Lenæa, as also of comedies at the Great Dionysia, in the performances at which festival tragedies greatly predominated. It will help to show the relation between the Lenæa and the Great Dionysia that at the former foreigners were not, as at the latter, excluded from choruses, and also that the resident aliens (*μέτοικοι*) might at the Lenæa serve as *choragi*, which again was not permitted at the Great Dionysia.

3. *The Anthesteria*, deriving its name from the time of year at which it was held, the month of flowers, is a festival differing materially from the other three, inasmuch as it appears to have comprehended no public dramatic performances. It is inferred however by Hermann, from a law mentioned in the *Lives of the Ten Orators* (Pseud. Plut. vi. p. 253), and from other stray allusions to contests taking place at this festival, that plays were now rehearsed before small audiences, which were to be performed at the Great Dionysia in the succeeding month. Neither was there at the Anthesteria, as at the Lenæa and Great Dionysia, a public banquet provided by the state; but a certain sum, it is supposed, was given to each citizen, with which he was to provide his own repast. (Plut. *Resp. Ger. Pr.* c. 25.) The festival lasted during three days, which respectively bore the names *Pithoegia*, *Choes*, and *Chytiri*. On the first day, as is to be inferred from the name, the wine of the preceding vintage was broached and tasted, and on the second, we may suppose, the new wine was drunk. This was accounted a festival of great sanctity, and included many mysterious ceremonies for which none but the wife of the king-archon and a small number of priestesses (*γέραιραι*) were qualified. One ceremony was a mock marriage between the king-archon's wife and Dionysus. (Demosth. *Neær*, p. 1369.) The Anthesteria were, like the Lenæa, under the superintendence of the king-archon. As during the Roman Saturnalia, the slaves enjoyed a temporary freedom during this festival; it was a custom also to send presents, and, as at the Roman Quinquatria, to pay one's instructors on the occasion of the Anthesteria. (Athen. x. 437.)

4. *The City or Great Dionysia*, or *Dionysia* without any epithet, the most splendid of the four festivals, were under the superintendence of the chief archon (*ἀρχὼν ἐπὶ νόμοις*). This festival was held at a time when Athens was filled with foreigners, those bringing the tribute from her dependent states, and others. (Aristoph. *Ach.* 474, &c.) It was celebrated with a public banquet at the expense of the state, and with dramatic performances, which consisted chiefly, as has been said in describing the Lenæa, of tragedies. Plays which had once won a prize were not allowed to be repeated, though a special exemption from this rule was granted to the plays of Æschylus upon his death, and subsequently to those of Sophocles and Euripides. And indeed, so far as we may conclude from instances, in the absence of any express mention of the regulation in the case of the Lenæa, we may say that it obtained at this festival also.

The times and occasions of the institution of these several festivals are wrapped up in obscurity. The Rural Dionysia, Lenæa, and Anthesteria, were connected with a rural worship of Dionysus or Bacchus, and were, it may be safely said, antecedent to the Great or City Dionysia; and it is, in comparison with this festival that Thucydides (ii. 15) calls the Anthesteria, more antient. The Lenæa and Anthesteria were festivals held in the deme Lenæus before it was inclosed within the city. The institution of the Great Dionysia seems to be referred to in a legend, which relates that

Pegasus brought an image of Dionysus Eleuthereus from Eleutheræ to Athens. Boeckh connects this with an historical tradition of the migration of the Eleutherians from their town to Athens, and conjectures that the migration, and, as he supposes, consequent institution of the Great Dionysia, preceded by a little the return of the Heraclides (1124 B.C.). Welcker, who assigns to the epithet Eleuthereus and other epithets of Dionysus a political meaning, connects with the progress of his rites in the Athenian state the progress of political liberty. A short sketch of Welcker's views, which were propounded by him in his *Nachtrag* (*Supplement to the Treatise on the Æschylean Trilogy*), is given in the article in the Philological Museum which has been already referred to.

DIONYSIUS THE ELDER was born at Syracuse about 430 B.C. In the civil troubles of Syracuse, between the party of Diocles and that of Hermocrates, who was accused of aspiring to the supreme power, Dionysius took part with the latter and was wounded in an attempt which Hermocrates made to take possession of Syracuse. He afterwards married the daughter of Hermocrates. Meantime the Carthaginians had effected their second invasion of Sicily, and had taken Selinus, Himera, and Agrigentum. (Xenophon, *Hellenika*, ii. 2.) All Sicily was in danger of falling into the hands of the conquerors. In the assembly of the people of Syracuse, convoked after the fall of Agrigentum, Dionysius accused the commanders and the magistrates of neglect and treachery. In consequence of this charge he was condemned to a heavy fine, which Philistus, the historian, paid for him, and he then repeated his charges against those who were at the head of the commonwealth, until he persuaded the people to change the military commanders, and appoint new ones, among whom himself was one. His next measure was to obtain the recall of the exiles, to whom he gave arms. Being sent to the relief of Gela, then besieged by the Carthaginians, he effected nothing against the enemy, pretending that he was not seconded by the other commanders, and his friends suggested that in order to save the state the supreme power ought to be confided to one man, reminding the people of the times of Gelon, who had defeated the Carthaginian host and given peace to Sicily. The general assembly proclaimed Dionysius supreme chief of the republic about 405 B.C. when Dionysius was 25 years of age. He increased the pay of the soldiers, enlisted new ones, and under pretence of a conspiracy against his person, formed a guard of mercenaries. He then proceeded to the relief of Gela, but failed in his attack on the Carthaginian camp; he however penetrated into the town, the inhabitants of which he advised to leave it quietly in the night under the escort of his troops. On his retreat he persuaded those of Camarina to do the same. This raised suspicions among his troops, and a party of horsemen, riding on before the rest, on their arrival at Syracuse raised an insurrection against Dionysius, plundered his house, and treated his wife so cruelly that she died in consequence. Dionysius, with a chosen body, followed close after, set fire to the gate of Acradina, forced his way into the city, put to death the leaders of the revolt, and remained undisputed possessor of the supreme power. The Carthaginians, being afflicted by a pestilence, made proposals of peace, which were accepted by Dionysius, on condition that they should retain, besides their old colonies, the territories of Agrigentum, Selinus, and Himera; that Gela and Camarina should be restored to the inhabitants, who were to pay tribute to the Carthaginians, and that Messana, Syracuse, Leontini, and the whole eastern division of the island as well as the towns of the Siculi, in the interior, should remain independent. Himilco with the Carthaginian army returned to Africa, and Dionysius applied himself to fortify Syracuse, and especially the island Ortygia, which he made his strong hold, and which he peopled entirely with his trusty partisans and mercenaries, by the aid of whom he put down several revolts which broke out against him. He took, partly by stratagem and partly by force, the towns of Leontini, Catana, and Naxos, and subjected them to Syracuse. He next prepared for a new war against Carthage by collecting men from every quarter, manufacturing a large quantity of arms, and inventing new engines for besieging towns. The termination of the Peloponnesian war (B.C. 404) had filled the Greek towns of Sicily with emigrants and disbanded mercenaries, many of whom Dionysius enlisted in his service. In the year 397 B.C. he convoked a general assembly of the people and proposed the war, which was unanimously voted, and

which was begun by the people plundering the houses and vessels of the Carthaginian traders. Dionysius sent a herald to Carthage, which was then afflicted by the plague, to declare war, unless all the Greek towns in Sicily were evacuated. He next laid siege to Motya, one of the principal Carthaginian colonies in Sicily, which his brother Leptines attacked by sea. In this siege he tried his new engines, which battered down the walls, and the town being taken, the inhabitants were either killed or sold, and an immense booty was made by the Syracusans. Dionysius reduced also the other towns belonging to the Carthaginians, except Panormos, Soloeis, and Egeste. Meantime the Carthaginians collected a large force under Himilco, who landed at Panormos, while his fleet took the island of Lipara; he then marched against Messana, which he took and destroyed; and thence advanced towards Syracuse. Most of the towns inhabited by the Siculi joined the Carthaginians. On arriving at Tauromenium Himilco found his way along the sea-coast, but was stopped by a great eruption of lava from Ætna, and was obliged to march round by the western base of the mountain. Meantime Mago with the Carthaginian fleet attacked the Syracusan fleet off Catana, and completely defeated it. Himilco encamped under the walls of Syracuse, while his victorious fleet entered the great harbour. Dionysius, on his side, received ships and men from Sparta. A dreadful pestilence breaking out in Himilco's camp, Dionysius availed himself of it to attack the Carthaginians, defeated them, and burnt most of their ships. Himilco with the remainder escaped to Carthage, having paid secretly a large sum to Dionysius for his forbearance.

Dionysius settled the disbanded mercenaries as colonists at Leontini and Messana, which latter city he caused to be rebuilt. Mago, with a new Carthaginian army, having landed in Sicily, 392 B.C., was compelled to reimbarc on condition of paying the expenses of the war. Dionysius now proceeded against Rhegium, with which the other towns of Magna Græcia had formed an alliance, while he gained over to his side the Lucanians, and both together defeated the allies, devastated the territories of Thurii, Croton, Caulon, Hipponium, and Locri, and obliged the Greeks to sue for peace. About this time he is said by Justinus, xx. 5, to have received an embassy from the Gauls, who had just burnt Rome, offering him their alliance. In 387 B.C. he again attacked Rhegium, and took it after a long and obstinate siege. He sold the surviving inhabitants as slaves, and put their commander to a cruel death.

Dionysius was now feared both in Italy and Sicily, and he seems to have aspired at one time to the dominion of both countries. In order to raise money, he allied himself with the Illyrians, and proposed to them the joint plunder of the temple of Delphi: the enterprise however failed. He then plundered several temples, such as that of Proserpina, at Locri, and as he sailed back with the plunder with a fair wind, he, who was a humorist in his way, observed to his friends, 'You see how the immortal Gods favour sacrilege.' Having carried off a golden mantle from a statue of Jupiter, consecrated by Gelon out of the spoils of the Carthaginians, he replaced it by a woollen garment, saying that it was more suited to the vicissitudes of the seasons: he also took away a golden beard from Æsculapius, observing it was not becoming for the son of a beardless father (Apollo) to make a display of his beard. He likewise appropriated to himself the silver tables and golden vases and crowns in the temples, saying he would make use of the bounty of the Gods. (Cicero, *De Natura Deorum*, iii. 34; Ælianus, *Histor.*, i. 20.) He also made an invasion with a fleet on the coast of Etruria, and plundered the temple of Cære, or Agylla, of 1000 talents. With these resources he was preparing himself for a new expedition to Italy, when a fresh Carthaginian armament landed in Sicily, 383 B.C., and defeated

Dionysius, whose brother, Leptines, fell in the battle. A peace followed, of which Carthage dictated the conditions. The boundary of the two states was fixed at the river Halycus, and Dionysius had to pay 1000 talents for the expenses of the war. This peace lasted fourteen years, during which Dionysius remained the undisturbed ruler of Syracuse and one-half of Sicily, with part of Southern Italy. He sent colonies to the coasts of the Adriatic, and his fleets navigated both seas. Twice he sent assistance to his old ally, Sparta, once against the Athenians, 374 B.C., and again in 369, after the battle of Leuctra, when the Spartans were hard pressed by Epaminondas. Meantime the court of Dionysius was frequented by many distinguished men, philosophers and poets. Plato is said to have been among the former, being invited by Dion, the brother-in-law of Dionysius; but the philosopher's declamations against tyranny led to his being sent away from Syracuse. The poets fared little better, as Dionysius himself aspired to poetical glory, for which however he was not so well qualified as for political success. Those who did not praise his verses were in danger of being sent to prison. Dionysius twice sent some of his poems to be recited at the Olympic games, but they were hissed by the assembly. He was more successful at Athens. A tragedy of his obtained the prize, and the news of his success almost turned his brain. He had just concluded a fresh truce with the Carthaginians, after having made an unsuccessful attack upon Lilybæum at the expiration of the fourteen years' peace; and he now gave himself up to rejoicings and feasting for his poetical triumph. In a debauch with his friends, he ate and drank so intemperately that he fell senseless, and soon after died; some say he was poisoned, 367 B.C., in the sixty-third year of his age, having been tyrant of Syracuse thirty-eight years. After the death of his first wife he married two wives at once, namely, Doris of Locri, and Aristæneta, daughter of Hipparinus, of Syracuse: by these women he had seven children, of whom Dionysius, his elder son by Doris, succeeded him in the sovereignty.

Dionysius was a clever statesman, and generally successful in his undertakings; he did much to strengthen and extend the power of Syracuse, and it was probably owing to him that all Sicily did not fall into the hands of the Carthaginians after the taking of Agrigentum. He was unscrupulous, rapacious, and vindictive, but several of the stories stated of his cruelty and suspicious temper appear improbable, or at least exaggerated. The works of Philistus, who had written his life, and who is praised by Cicero, are lost. Diodorus, who is our principal remaining authority concerning Dionysius, lived nearly three centuries after, and was not a critical writer. The government of Dionysius, like that of many others who are styled tyrants in ancient history, was not a despotism; it resembled rather that of the first Medici and other leaders of the Italian republics in the middle ages, or that of the Stadtholders in Holland. The popular forms still remained, and we find Dionysius repeatedly convoking the assembly of the people on important occasions, when full freedom of speech seems to have been allowed.

Coin of Dionysius.

British Museum. Actual size. Silver. Weight, 263 grains.
